The samples were stored frozen (at −21° C) until assayed for 6-keto-prostaglandin $F_{1\alpha}$ (6-keto-$PGF_{1\alpha}$), 2,3-dinor-6-keto-prostaglandin $F_{1\alpha}$ (2,3-dinor-6-keto-$PGF_{1\alpha}$), thromboxane B_2 (TxB_2), and 2,3-dinor-TxB_2 by means of high-performance liquid chromatography followed by radioimmunoassays. The details of all methods except for 2,3-dinor-TxB_2 are given elsewhere[16]; as regards 2,3-dinor-TxB_2, it eluted from high-performance liquid chromatography concomitantly with 6-keto-$PGF_{1\alpha}$ and was assayed with tritium-labeled TxB_2 as a tracer and TxB_2 antibody that has approximately 40% cross reactivity with 2,3-dinor-TxB_2. Creatinine was determined by a routine method, and the prostanoid output was expressed against creatinine excretion.

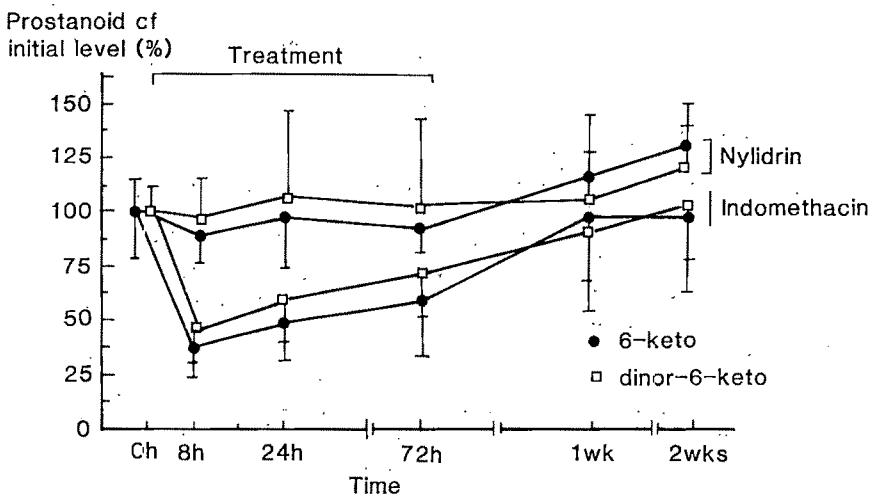

Fig. 1. Mean (± SE) urinary excretion of PGI_2 metabolites (6-keto-$PGF_{1\alpha}$ and 2,3-dinor-6-keto-$PGF_{1\alpha}$) as percentage of initial level in patients with indomethacin and nylidrin treatment. Drops were significant ($p < 0.05$) at 8, 24, and 72 hours during indomethacin treatment but insignificant during nylidrin treatment (Student t test). For numbers of observations see text.

Table II. Urinary excretion of PGI_2 (6-keto-$PGF_{1\alpha}$, 2,3-dinor-6-keto-$PGF_{1\alpha}$) and thromboxane (TxB_2, 2,3-dinor-TxB_2) metabolites and their ratios in women in preterm labor as compared with gestational age–matched control women and women in term labor

	Preterm labor (n = 33)		*Gestational age–matched preterm controls (n = 25)*		*Term labor (n = 28)*	
	Median	*Range*	*Median*	*Range*	*Median*	*Range*
Prostanoid (ng/mmol creatinine)						
6-Keto-$PGF_{1\alpha}$	35.0[a]	13.5-136.0	32.6[b]	6.0-80.9	59.4[c]	8.5-207.4
2,3-Dinor-6-keto-$PGF_{1\alpha}$	44.8[d]	15.9-120.5	38.5[e]	8.1-107.1	40.0	15.6-122.0
TxB_2	17.5[f]	2.6-105.9	11.1[g]	0.7-30.6	18.7	4.2-272.9
2,3-Dinor- TxB_2	77.4[h]	12.1-383.5	54.2[i]	1.7-143.7	73.2	24.2-333.3

$\frac{\text{2,3-Dinor-6-keto-PGF}_{1\alpha}}{\text{2,3-Dinor-TxB}_2}$	0.6[l]	0.1-2.4	0.8[m]	0.1-4.8	0.6	0.1-2.3
$\frac{\text{6-Keto-PGF}_{1\alpha} + \text{2,3-dinor-6-keto-PGF}_{1\alpha}}{\text{TxB}_2 + \text{2,3-dinor-TxB}_2}$	0.9[n]	0.1-2.9	1.1[o]	0.2-7.6	1.1	0.2-3.5

Wilcoxon test, $p < 0.05$, *a* compared with *b*, *a* with *c*, *d* with *e*, *f* with *g*, and *h* with *i*. Student t test, $p < 0.05$, *j* compared with *k*, *l*, with *m*, and *n* with *o*.

Statistical analyses were done by paired and unpaired Student t test for parametric data, by Spearman's correlation, and by Wilcoxon signed rank test for nonparametric data. In addition to the individual prostanoid output, PGI_2 metabolites (6-keto-$PGF_{1\alpha}$ and 2,3-dinor-6-keto-$PGF_{1\alpha}$) and TxA_2 metabolites (TxB_2 and 2,3-dinor-TxB_2) also were summarized to reflect the total production of the parent compound. To better demonstrate any possible treatment-induced changes in prostanoid excretions, they were also expressed as percentages of the initial output.

Results

Preterm labor was accompanied by increased outputs of all prostanoids measured (Table II). The ratio of PGI_2 to TxA_2 metabolites was approximately 36% lower for preterm labor women than for preterm control women (Table II). No relationship was evident between individual prostanoid excretion and days gained by tocolysis, nor there was any difference in prostanoid output between the women ($n = 15$) who subsequently gave birth before the thirty-seventh gestational week and those who proceeded to term ($n = 18$).

There also was no difference in the pretreatment output of prostanoid metabolites between the indomethacin and nylidrin groups (detailed analysis not shown). Indomethacin treatment was accompanied by maximal drops in 6-keto-$PGF_{1\alpha}$ (70% ± 9.1%, SE) and 2,3-dinor-6-keto-$PGF_{1\alpha}$ (60% ± 9.4%, SE) and by maximal drops in TxB_2 (85% ± 8.6%, SE) and 2,3-dinor-

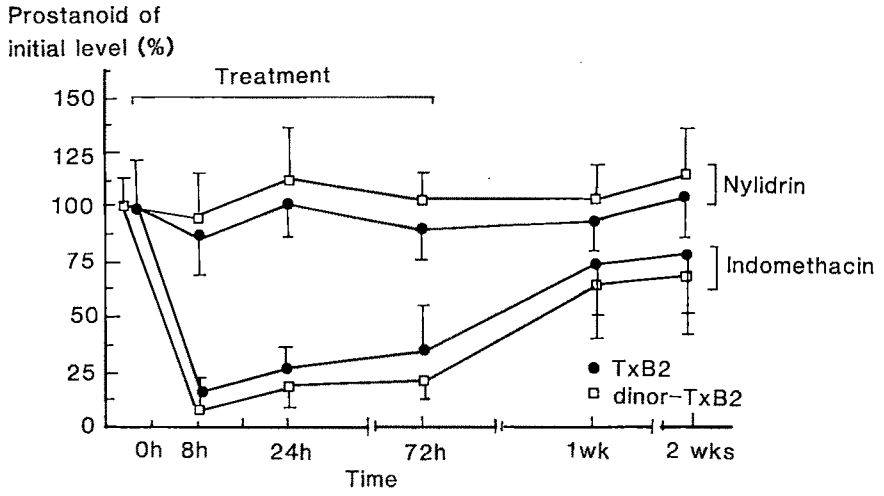

Fig. 2. Mean (±SE) urinary excretion of TxA_2 metabolites (TxB_2 and 2,3-dinor-TxB_2) as percentage of initial level in patients with indomethacin and nylidrin treatment. Drops were significant ($p < 0.05$) at 8, 24, and 72 hours during indomethacin treatment but insignificant during nylidrin treatment (Student t test). For numbers of observations see text.

TxB_2 excretion (95% ± 7.9%, SE) at 8 hours after the start of the tocolysis, whereas nylidrin induced no significant changes (Figs. 1 and 2). Indomethacin treatment decreased TxA_2 (TxB_2 and 2,3-dinor-TxB_2) approximately 35% more ($p < 0.05$) than it did PGI_2 (6-keto-$PGF_{1\alpha}$ and 2,3-dinor-6-keto-$PGF_{1\alpha}$) excretion, resulting in an increased ratio of PGI_2 to TxA_2 metabolites from 1.2 ± 0.2 to the maximum of 3.4 ± 0.7 (SE) ($p < 0.05$) within 8 to 72 hours after the start of indomethacin (Figs. 1 and 2). Within 1 week after cessation of indomethacin, the output of PGI_2 metabolites had recovered to pretreatment levels (Fig. 1), whereas output of TxA_2 metabolites remained lower than the pretreatment value (Fig. 2).

During term labor the excretion of these prostanoids increased in relation to cervical dilatation: 6-keto-$PGF_{1\alpha}$ ($r = 0.6$, $p = 0.001$), 2,3-dinor-6-keto-$PGF_{1\alpha}$ ($r = 0.4$, $p = 0.044$), TxB_2 ($r = 0.6$, $p = 0.002$), and 2,3-dinor-TxB_2 ($r = 0.5$, $p = 0.008$). When the individual prostanoid output figures during term labor were considered in isolation from cervical dilatation, term labor was accompanied by a higher ($p < 0.05$) output of 6-keto-$PGF_{1\alpha}$ (median, 59.4; range, 8.5 to 207.4 ng/mmol creatinine) than was preterm labor (median, 35.0; range, 13.5 to 136.0), whereas all the other prostanoid output figures and the ratio of PGI_2 to TxA_2 metabolites did not show any difference between women in term and preterm labor.

During the first 8 hours of treatment nylidrin induced a significant drop in diastolic blood pressure from a median of 60 (range, 50 to 80) to a median of 50 (range, 30 to 70) mm Hg; this change disappeared after 8 hours. The magnitude of the fall in diastolic blood pressure was of no relation to PGI_2 or TxA_2 output. Indomethacin induced no changes in blood pressure.

Comment

At present the in vivo production of PGI_2 and TxA_2 is measured by determining the urinary metabolites of the parent compounds, although it is not totally clear to what extent they reflect systemic and to what extent renal prostanoid synthesis.[17, 18] The best index of systemic PGI_2 production is considered to be urinary 2,3-dinor-6-keto-$PGF_{1\alpha}$, and 2,3-dinor-TxB_2 is the best index of TxA_2 production by circulating platelets,[19] whereas the majority of 6-keto-$PGF_{1\alpha}$ and TxB_2 may arise from the kidneys.[20] In our study we assessed all four of these prostanoids.

Abundant evidence suggests a role for prostaglandins in the initiation of term human labor.[6-8] Thus activation of arachidonic acid metabolism also could induce preterm labor, although so far there has been little in vivo evidence to support this claim. In the only earlier work Noort[21] found increased amounts of urinary TxB_2 in women in imminent preterm labor. This was confirmed in our study, although we could not demonstrate any value for TxB_2 assay in predicting the outcome of tocolysis in individual patients. As a new finding, the excretion of 2,3-dinor-TxB_2, 6-keto-$PGF_{1\alpha}$, and 2,3-dinor-6-keto-$PGF_{1\alpha}$ also was elevated in threatened preterm labor. Premature uterine activity thus seems to be associated with general stimulation in prostanoid synthesis. However, our current data do not reveal whether this stimulation is a primary change, perhaps connected to the onset of contractions, or a secondary change resulting from the compliance of the uterus and vascular system to preterm contractions. In theory the dominance of the production of contraction/promoting TxA_2,[5] as evident in our study, could be involved in the onset or maintenance of contractions.

Maternal indomethacin treatment caused a transient constriction of the ductus arteriosus in seven of 14

fetuses[11] and of cerebral arteries in six of 13 fetuses.[12] In view of the significant role of PGI_2 in ductal patency,[1-3] PGI_2 suppression is a probable explanation, although no in vivo data on the effect of indomethacin on PGI_2 during pregnancy have been available. We present now the first in vivo evidence that maternal indomethacin suppresses the synthesis of PGI_2, although we do not know the exact site where indomethacin takes this action. It may inhibit PGI_2 on both the maternal and the fetal side,[13] and the suppression in fetal PGI_2 synthesis may be one explanation for the fetal vessels' constriction.[11, 12] PGI_2 synthesis did recover within 1 week after indomethacin treatment, which fits in with the findings that ductal constriction vanishes within the same time after cessation of indomethacin.[11, 22]

β-Sympathomimetic-induced vasodilatation often has been supposed to be due to the excess of PGI_2,[10] and this was supported by small rises in maternal plasma 6-keto-$PGF_{1\alpha}$ after ritodrine infusion.[14] As assessed by its urinary metabolites, nylidrin did not increase PGI_2 production, although a significant fall in diastolic blood pressure ensued. Thus nylidrin and probably also the other β-sympathomimetics are unlikely to affect PGI_2 synthesis in vivo. Also in vitro models β-sympathomimetics had no effect on PGI_2 synthesis.[23] That nylidrin does not affect PGI_2 synthesis in vivo is a finding in harmony with unchanged ductal flow during maternal nylidrin infusion.[22]

We conclude that threatened preterm labor is associated with increased PGI_2 and TxA_2 synthesis and with TxA_2 dominance. Indomethacin suppresses the production of PGI_2 and, even more, that of TxA_2, which may be one reason for the tocolytic efficacy of indomethacin. However, nylidrin has no effect on these prostanoids. Inhibition of fetal PGI_2 synthesis during maternal indomethacin administration may be one reason for the ductal constriction during such a treatment.

Substance P in peritoneal fluid

Joseph S. Sanfilippo, MD, R. Stanford Williams, MD, Marvin A. Yussman, MD, Christine L. Cook, MD, and Francois Bissonnette, MD

Louisville, Kentucky

Substance P is a neuropeptide that has been identified in the ovary, fallopian tube, uterus, and vagina and in the hypothalamic-pituitary axis in both an animal model and human ovaries. We sought to determine if substance P is present in peritoneal fluid and, if so, whether it correlated with the cause of infertility. Its presence was determined by radioimmunoassay in the peritoneal fluid of 66 patients undergoing diagnostic laparoscopy for clinical indications related to infertility. Total volume of peritoneal fluid and cycle day were recorded; patients were evaluated in groups according to diagnosis: endometriosis (n = 24), pelvic adhesions (n = 18), and normal controls (n = 24). The level of substance P (mean ± SEM) was 122 ± 19 pg/ml for endometriosis and 130 ± 19 pg/ml for pelvic adhesions. These values were not significantly different from the normal controls (130 ± 25 pg/ml). There was no significant difference in levels between follicular and luteal phase of the menstrual cycle. We conclude that substance P is present normally in peritoneal fluid and that its levels are not affected by pelvic endometriosis or adhesions. (Am J Obstet Gynecol 1992;166:155-9.)

Substance P is a brain-gut peptide consisting of 11 amino acids and belonging to the family of tachykinins. In the brain it behaves as a neuropeptide and may have a physiologic role as an inhibitor of gonadotropin-releasing hormone.[1] In the gastrointestinal and urogenital tracts substance P has a stimulatory effect on smooth muscles. The neuropeptide also acts on the

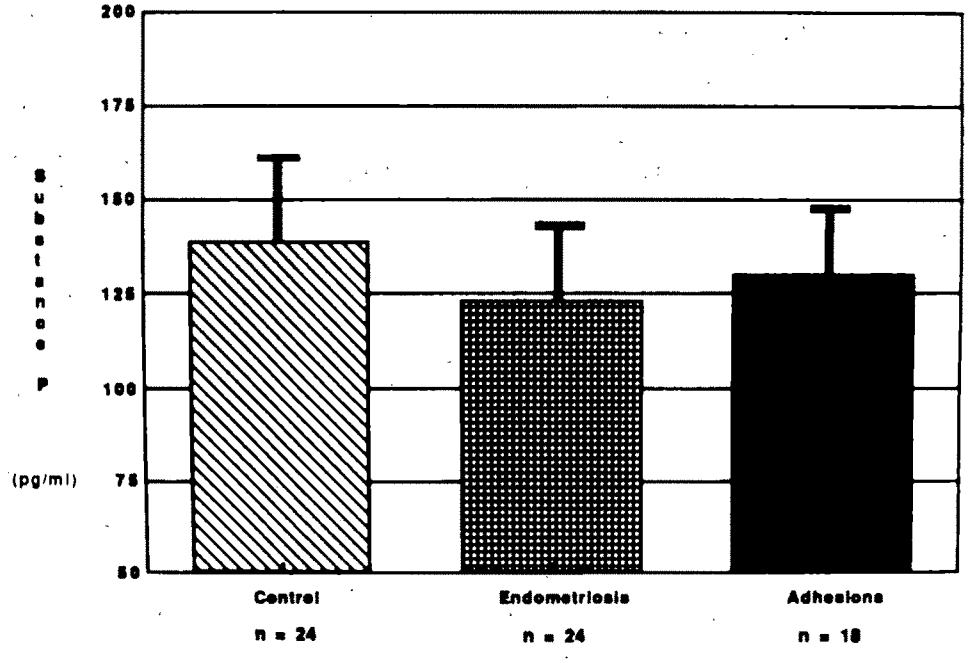

Fig. 1. Substance P in peritoneal fluid for patients with endometriosis and adhesions and control population. (Substance P levels are expressed in picograms per milliliter.)

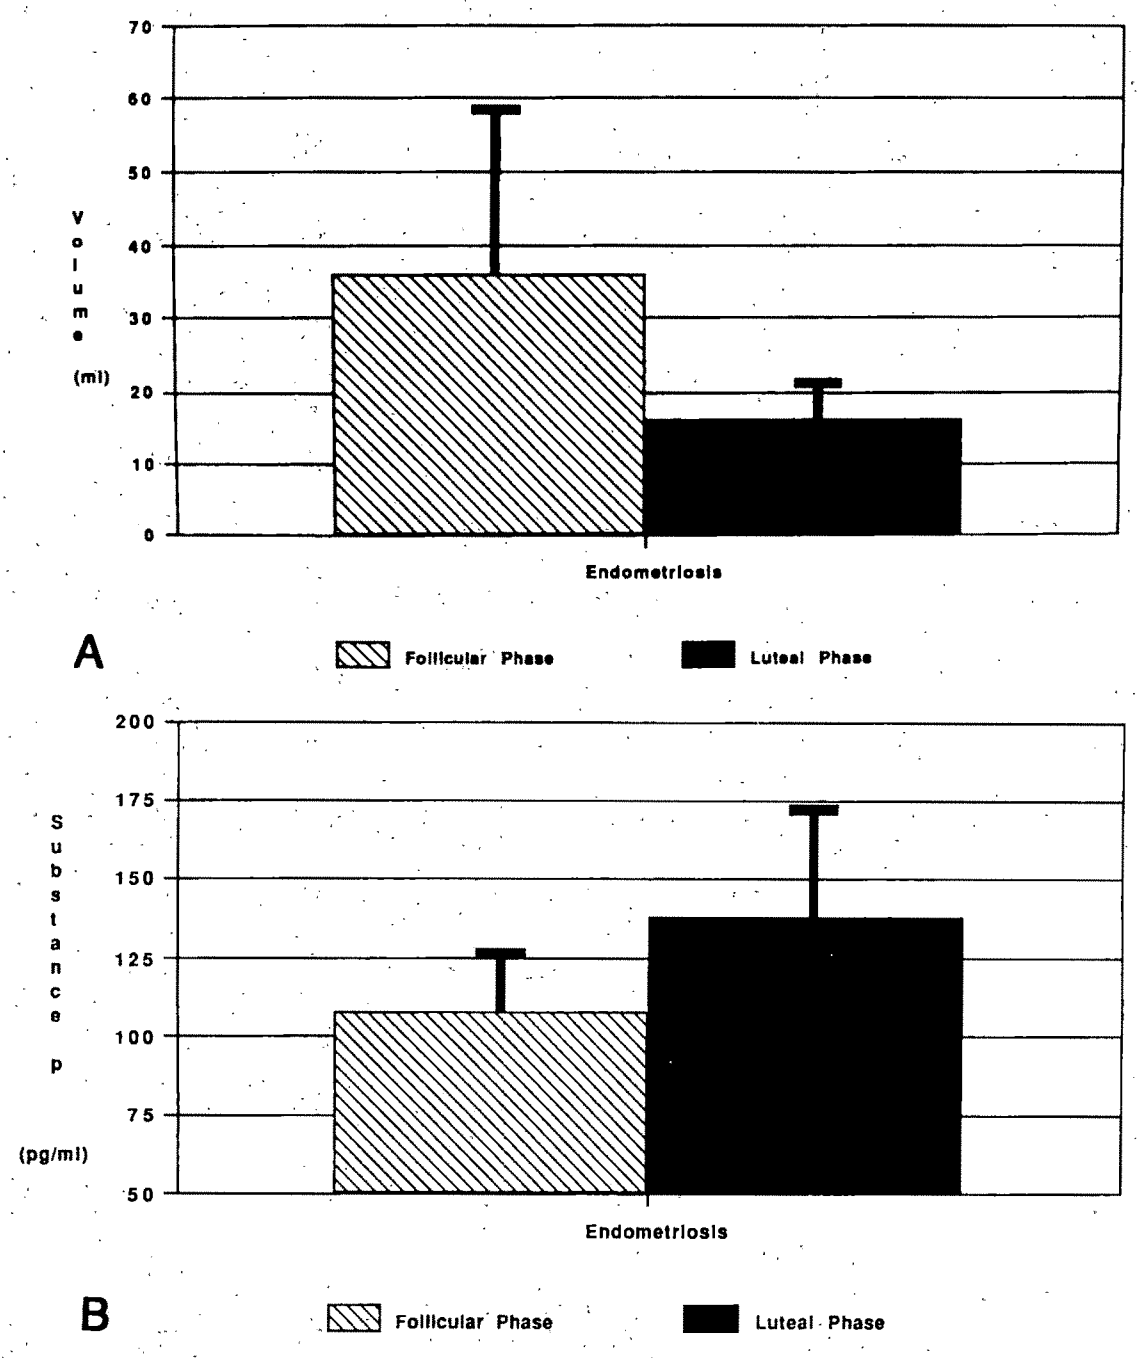

Fig. 2. A, Comparison of peritoneal fluid volumes in follicular versus luteal phases of menstrual cycle in patients with endometriosis. **B,** Substance P levels in endometriosis population, follicular versus luteal phase.

smooth muscles of blood vessels, resulting in vasodilatation.[2]

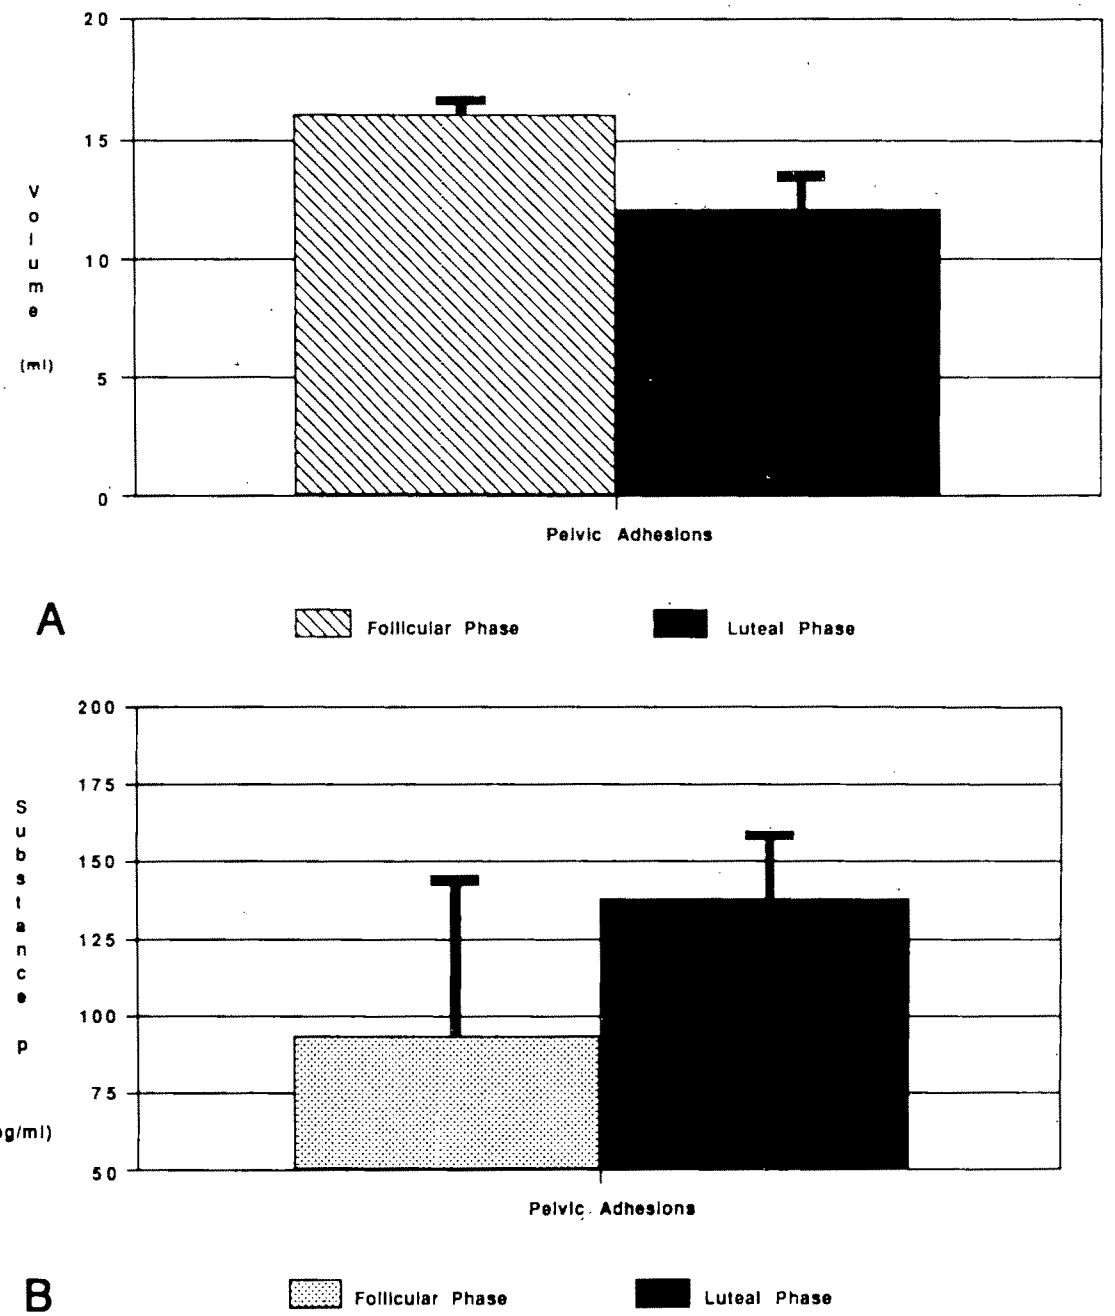
Substance P has been isolated from the ovaries, fallopian tubes, uterus, and hypothalamic-pituitary axis in animal models.[2] It also has been isolated from human ovaries and is found in high concentrations in primary ovarian carcinoid.[3]

The fallopian tube is extremely sensitive to tachykinins. Exposure of fallopian tubes to tachykinins causes an increase in tubal motility. It has been suggested that the increased tubal motility that occurs during ovulation could be mediated by the local release of tachykinins.[4]

The objective of this study was to determine if substance P normally is present in peritoneal fluid and, if so, whether its level is affected by the presence of pelvic pathologic conditions.

Material and methods

Sixty-six patients were evaluated. Each individual underwent diagnostic laparoscopy for evaluation of infertility, sterilization, or chronic pelvic pain and con-



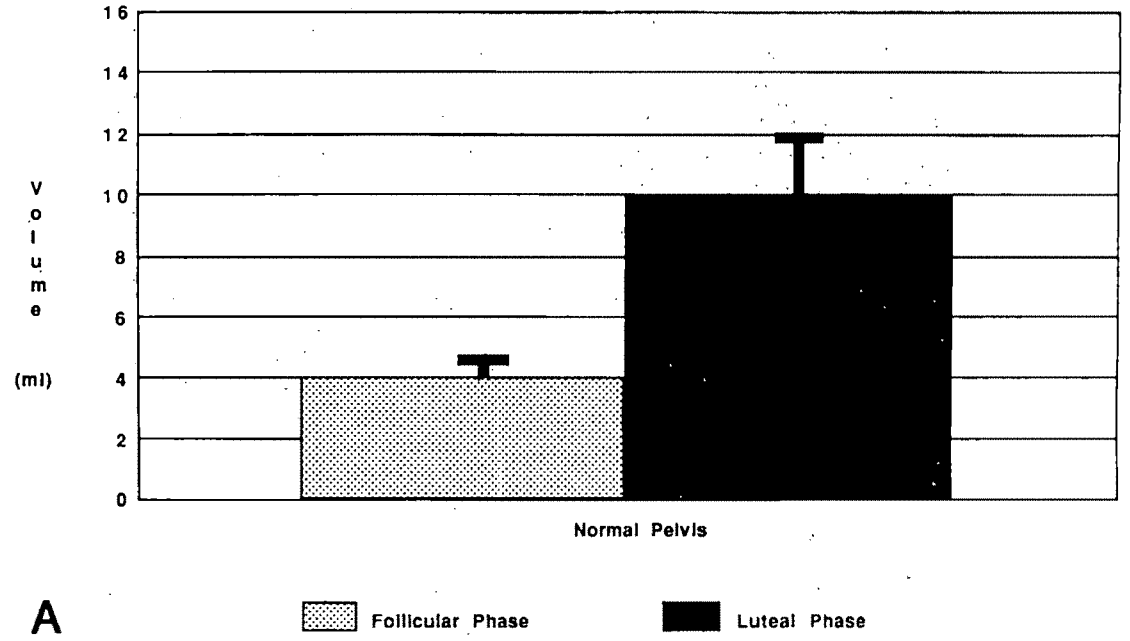


Fig. 3. A, Comparison of peritoneal fluid volumes in follicular versus luteal phase of menstrual cycle in patients with pelvic adhesions. **B,** Substance P levels in pelvic adhesion population, follicular versus luteal phase.

sented to removal of peritoneal fluid for analysis of substance P. Prior institutional review board approval was obtained. Each patient's menstrual cycle day, total peritoneal fluid volume, and intraoperative findings were recorded. If endometriosis (n = 24) was present, it was classified according to the American Fertility Society classification revised in 1988. Adhesions were present in 10 patients, and all were filmy and avascular. Patients with normal pelvic findings (n = 24) served as controls. Phase of the menstrual cycle and total volume of peritoneal fluid were determined.

Radioimmunoassay for substance P. After measuring the total volume of fluid obtained, an aliquot of fresh peritoneal fluid was placed in an ultracold (−70° C) freezer until the assay was performed. The samples were thawed in an ice bath (0° C). An acetone extraction of substance P was obtained from peritoneal fluid.

Radioimmunoassay of substance P was carried out with kits and protocols supplied by the Immuno Nuclear Corporation, Stillwater, Minn. In essence, rabbit anti–substance P serum and iodine 125–substance P was used with both substance P standards and perito-

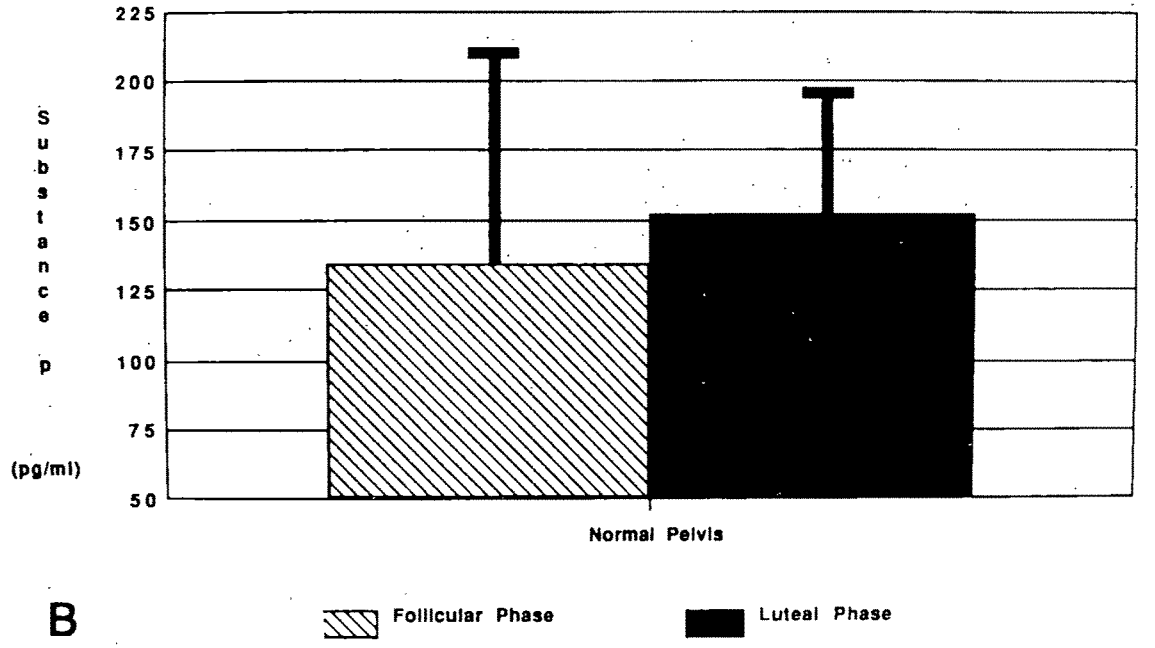

Fig. 4. A, Comparison of peritoneal fluid volumes in follicular versus luteal phase of menstrual cycle in control patient population. **B,** Substance P levels in control population, follicular versus luteal phase.

neal fluid samples (duplicates of each standard and sample).

After incubation, rabbit γ-globulin was added to all tubes, followed by saturated ammonium sulfate, followed by a second incubation. The supernatant was aspirated, and the precipitate of each tube was counted in a γ-scintillation counter. To calculate the percent bound per total count, the following formula was used:

$$\% \text{ Bound/total count} = \frac{\text{counts/min of standard or sample}}{\text{counts/min of total count tube}}$$

A standard curve was prepared by plotting the percent bound on the ordinate and the concentration of the standards in picograms per milliliter on the abscissa. The substance P value was read off the standard curve.

The assay was tested for cross-reactivity with related peptides—methionine enkephalin, leucine enkephalin, β-endorphin, eledoisin, and physalaemin. The interassay coefficient of variation equaled 17.3%, and the intraassay coefficient of variation equaled 7.8%. The assay resulted in a 0.008% cross reactivity with the peptides. Analysis of variance tests were used for statistical analysis.

Results

Patients with endometriosis ($n = 24$) were classified as stage 1 ($n = 2$), stage 2 ($n = 16$), stage 3 ($n = 2$), or stage 4 ($n = 4$). There was no significant difference in substance P levels among stages 1 to 4 of endometriosis. The levels of substance P (expressed in picograms per milliliter, mean ± SEM) in peritoneal fluid for patients with endometriosis (122 ± 19 pg/ml), pelvic adhesions (130 ± 19 pg/ml), and controls (139 ± 25 pg/ml) were not significantly different (Fig. 1).

Levels of substance P in peritoneal fluid were compared in all groups by menstrual phase. There was no significant difference noted between substance P level in the proliferative phase (104 ± 20 pg/ml) and luteal phase (137 ± 17 pg/ml) among study patients nor was there a statistical difference in total volume of fluid between proliferative and luteal phase with the three patient groups: endometriosis 12.6 ± 3.0 ml adhesions 16.5 ± 0.9 ml, and control 5.0 ± 0.7 ml for the proliferative phase and endometriosis 15.8 ± 4.6 ml, adhesions 13.3 ± 2.2 ml, and control 9.8 ± 2.4 ml for the luteal phase (Figs. 2 to 4).

Comment

It has been theorized that the presence of substance P in peritoneal fluid may play a role in regulating tubal motility during ovulation, and alterations in the levels of substance P may alter tubal motility in pathologic conditions.[4] Alterations of substance P in peritoneal fluid associated with pelvic adhesions and endometriosis were investigated.

The levels of substance P in the peritoneum were approximately tenfold higher than in serum.[2] There was no statistical difference in substance P levels in peritoneal fluid between patients with a laparoscopically normal pelvis and patients with either pelvic adhesions or endometriosis. Nor was there a difference in the level of substance P in peritoneal fluid in the follicular phase of the menstrual cycle when compared with the luteal phase in any of the three groups.

In summary, this is a preliminary report noting the similar levels of substance P in peritoneal fluid in women with endometriosis and adhesions compared with controls. The physiologic role of such high levels of substance P in peritoneal fluid on the reproductive tract remains to be determined.

Partial hydatidiform moles have impaired differentiated function (human chorionic gonadotropin and human placental lactogen secretion) in response to epidermal growth factor and 8-bromo-cyclic adenosine monophosphate

Donald W. Morrish, MD, PhD,[a] Louis H. Honoré, MB,[b] and Damyanti Bhardwaj, MD[a]
Edmonton, Alberta, Canada

OBJECTIVE: The null hypothesis is that partial hydatidiform moles have normal differentiated function (human chorionic gonadotropin and human placental lactogen secretion) in response to epidermal growth factor and 8-bromo-cyclic adenosine monophosphate.
STUDY DESIGN: Two complete moles, 10 partial hydatidiform moles, and 19 normal first-trimester placentas in monolayer culture were exposed to 10 ng/ml epidermal growth factor, 1 mmol/L 8-bromo-cyclic adenosine monophosphate plus 1 mmol/L theophylline, or control. Human chorionic gonadotropin and human placental lactogen secretion was measured. Frequency of response to stimuli was compared by χ^2 analysis, and hormone secretion was compared by analysis of variance.
RESULTS: Partial moles demonstrated reduced frequencies of response of human chorionic gonadotropin and human placental lactogen to epidermal growth factor (partial moles 2/8 and 2/8, respectively; normal placentas 16/19 and 7/18, respectively; $p < 0.025$) and of human chorionic gonadotropin to 8-bromo-cyclic adenosine monophosphate (partial moles 3/5, normal placentas 13/16; $p < 0.005$).
CONCLUSION: Partial hydatidiform moles demonstrate impaired human chorionic gonadotropin and human placental lactogen secretory responsiveness to epidermal growth factor and cyclic nucleotides in comparison with normal first-trimester trophoblast. (Am J Obstet Gynecol 1992;166:160-6.)

Key words: Hydatidiform mole, human chorionic gonadotropin, human placental lactogen, epidermal growth factor, growth factors

Partial and complete hydatidiform moles, which are characterized by inappropriate hyperplasia of the villous tissue, demonstrate a variety of morphologic, antigenic, cytogenetic, and hormonal abnormalities.[1-13] Although β-human chorionic gonadotropin (hCG) has been most useful as a disease marker, no information is available regarding the regulation of hCG or other hormones produced by molar tissue. Therefore we wished to determine if there was abnormal regulation of hCG and human placental lactogen (hPL) secretion in response to epidermal growth factor (EGF) and 8-bromo-cyclic adenosine monophosphate (8-bromo-cAMP), two known stimulators of hormone secretion in normal trophoblast.

Material and methods

The study protocol was approved by the institutional ethics review board. Normal first-trimester placentas and hydatidiform mole tissue from spontaneous or therapeutic abortions were obtained and transported in sterile saline solution to the laboratory. Membranes were removed and the entire piece of placenta without dissection was then subjected to eight sequential 10-minute treatments with 0.25% trypsin/10 U/ml deoxyribonuclease I as previously described.[14] Cells were collected after the third to eighth treatment, pooled, centrifuged at 300*g*, and resuspended in Dulbecco's modified Eagle medium containing 10% fetal calf serum and 50 U/ml penicillin, 50 μg/ml streptomycin, and 0.2 mmol/L glutamine. Cells were plated in 60 mm Petri dishes and allowed to attach for 2 hours, after which the medium was changed to Dulbecco's modified Eagle medium without serum for the remainder of the experiment (7 to 9 days). Medium was changed daily and frozen at −20° C for subsequent hCG and hPL assay. After each medium change, plates received either 10 ng/ml EGF or bovine serum albumin (final concen-

tration 0.001%) for the duration of the culture period. To determine hCG responsiveness, 1 mmol/L 8-bromo-cAMP/1 mmol/L theophylline was added to separate plates on culture days 2 to 4. On days 6 to 9 cells were removed from some plates with 0.25% trypsin/0.02 mol/L ethylenediaminetetraacetic acid and counted on a hemocytometer.

Cytospun samples of freshly dispersed normal first-trimester and molar cells were stained by immunoperoxidase-ABC staining procedures as previously described[14] with monoclonal antisera directed against vimentin, cytokeratin, macrophages (HLe-1), and the $F(ab')_2$ fragments of oncomodulin, which were generated with a kit (ImmunoPur Fab Preparation Kit) from Pierce, Rockford, Ill. A syncytiotrophoblast-specific antiserum (GZ100) was also tested.[15] Incubation time was 72 hours at 4° C for oncomodulin and 4 hours at room temperature for all other antisera.

The gestational age of normal and molar placentas was calculated from date of last menstrual period.

Placentas were classified as responders or nonresponders to EGF and 8-bromo-cAMP/theophylline stimulation. A responder to EGF stimulation was defined as a placenta in which the integrated hormone secretion for 7 days of culture was significantly greater than control by paired *t* test. A responder to 8-bromo-cAMP/theophylline secretion was similarly defined, but only the 3 days of 8-bromo-cAMP/theophylline exposure were used in calculations. Comparison of the frequencies of stimulation between moles and first-trimester placentas was performed with Fisher's exact test or χ^2 analysis. Other comparisons were done with analysis of variance.

Trypsin was obtained from ICN Biomedicals Canada, Ltd., Montreal; deoxyribonuclease I, 8-bromo-cAMP, theophylline, Dulbecco's modified Eagle medium, ethylenediaminetetraacetic acid, penicillin-streptomycin, glutamine, and mouse EGF were obtained from Sigma Chemical Co., St. Louis; Petri dishes were from Corning Glass Co., Corning, N.Y.; and bovine serum albumin was from Miles Laboratories, Inc., Elkhart, Ind. Antisera were from Dimension Laboratories, Mississauga, Ontario (vimentin [Monosan]), and Becton-Dickinson Immunocytometry Systems, Mountain View, Calif. (cytokeratin, HLe-1). Oncomodulin polyclonal antiserum was kindly provided by Dr. J.P.

MacManus, National Research Council of Canada, Ottawa. Dr. G. Desoye, University of Graz, kindly provided the GZ100 monoclonal antiserum.

Results

Two complete and 10 partial moles were identified by standard morphologic criteria.[1] The identity and purity of the dispersed partial and complete mole and normal first-trimester cells were determined with multiple markers, as previously described[14] and are shown in Figs. 1 and 2. In the current studies two additional markers (oncomodulin and GZ100) were also used. Partial and complete moles showed positive staining for cytokeratin and oncomodulin and were negative for HLe-1 (macrophages) and vimentin (fibroblasts). An occasional vimentin-positive cell (<0.1%) was noted in

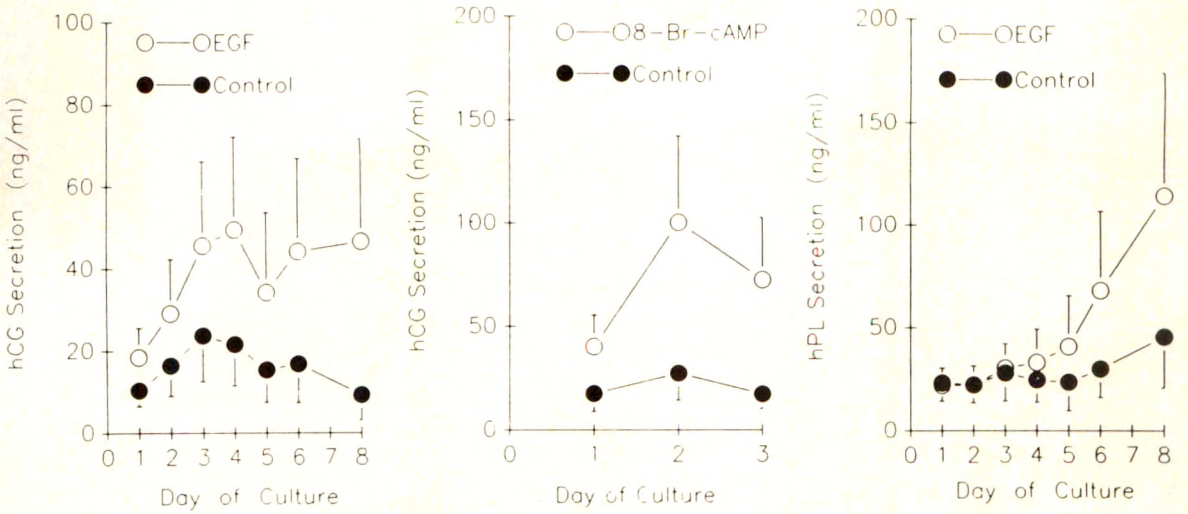

Fig. 3. Stimulation of hCG *(left panel)* and hPL *(right panel)* secretion by 10 ng/ml EGF and of hCG secretion *(middle panel)* by 1 mmol/L 8-bromo-cAMP/1 mmol/L theophylline of normal first-trimester trophoblast compared with controls. Mean ± SEM of responders appears in Table I. Responders were defined as having integrated hormone secretion over 7 culture days (EGF) or 3 culture days (8-bromo-cAMP/theophylline) that was significantly greater than control (see Material and methods). Each individual experiment (placenta) had significantly greater responses to stimuli than its own control. *Day of culture,* Culture day after EGF or 8-bromo-cAMP/theophylline was received.

the partial moles, but the one complete mole tested showed a higher percentage (10% to 15%) of vimentin-positive cells. No GZ100-positive cells were seen. GZ100 antiserum recognizes only first-trimester syncytiotrophoblast (Fig. 1, *b,* and Fig. 2, *b* and *c*).[15] Oncomodulin is a calcium-binding protein that is specific for cytotrophoblast.[16] The combination of these results indicates that the partial mole preparations were nearly pure cytotrophoblast. The complete mole was less purified. The results for normal first-trimester cytotrophoblast staining showed similar results (Fig. 2).[17] Vimentin staining was negative (data not shown), as in Fig. 1, *e,* and as reported.[17] GZ100 and oncomodulin staining of normal first-trimester trophoblast and partial and complete moles, not previously reported, permits positive identification of cytotrophoblast and exclusion of syncytial contamination. The pattern of expression of the antigens tested was the same in partial and complete moles and normal placentas.

Normal first-trimester placentas and molar tissue were collected and processed under identical conditions. Cell viability of isolated cell preparations was >95% in all preparations of both normal and molar tissue.

Table I shows the fraction of cultures that were responders or nonresponders to EGF and 8-bromo-cAMP/theophylline stimulation, using the classification of responders and nonresponders as defined in the Material and methods. By these criteria, EGF induced hCG and hPL secretion in two of eight partial moles and in 16 of 19 and seven of 18 normal first-trimester placentas, respectively. 8-Bromo-cAMP/theophylline induced hCG secretion in five of eight partial moles and 13 of 16 normal first-trimester placentas, respectively. Of the complete moles, two of two and none of two showed hCG and hPL responses to EGF, respectively, and one of two had an hCG response to 8-bromo-cAMP/theophylline. Too few complete moles were available for separate statistical comparisons with partial moles or normal placenta. Partial moles demonstrated reduced frequencies of response of hCG and hPL to EGF ($p < 0.025$, Fisher's exact test), and of hCG to 8-bromo-cAMP/theophylline ($p < 0.005$, χ^2 analysis) in comparison with normal first-trimester placenta. The mean fold or fractional increases in hormone response to EGF and 8-bromo-cAMP/theophylline (defined as EGF/control ratio for 7 culture days and 8-bromo-cAMP/theophylline/control ratio for 3 culture days) are also shown in Table I. By analysis of variance, most responders had significantly greater responses to stimuli than did nonresponders (Table I). Normal placenta and partial mole responders to EGF or 8-bromo-cAMP/theophylline did not show significant differences in the magnitude of increases of hCG or hPL (Table I). Figs. 3 and 4 show the increases in hCG and hPL secretion after EGF and 8-bromo-cAMP/theophylline stimulation in normal first-trimester and partial molar placenta responders, respectively. There was a gradual rise in secretion of hCG and hPL in both tissues in response to EGF during the culture period. Partial mole hCG responses were qualitatively less than those of normal placentas, but the differences were not statistically significant.

Secretion per cell was 0.70 ± 0.41 ng/ml hCG and 1.23 ± 0.21 ng/ml hPL, and the hPL/hCG ratio was 3.46 ± 1.89 (mean ± SEM) in partial moles. Normal

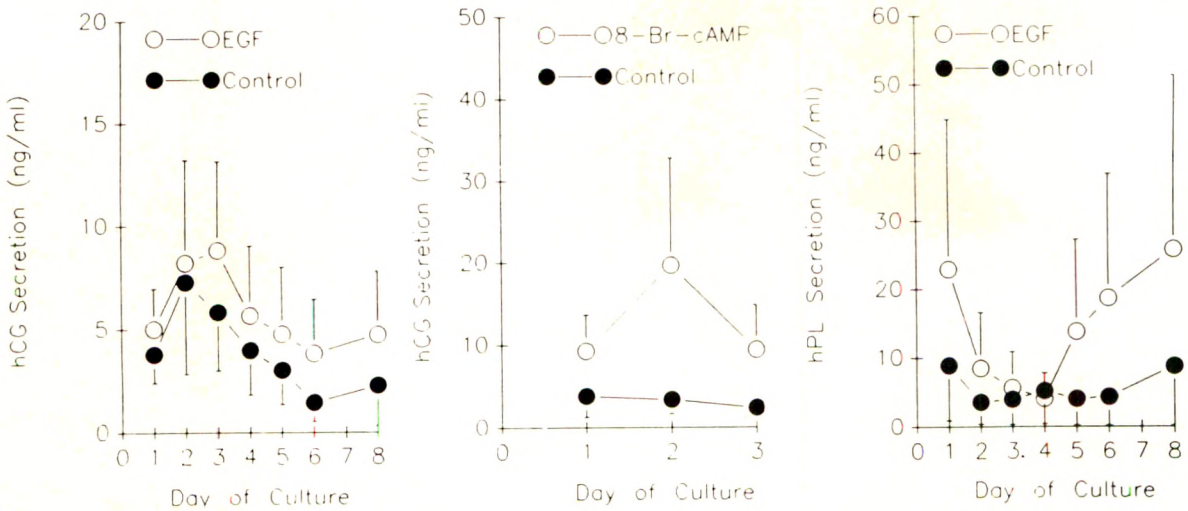

Fig. 4. Stimulation of hCG *(left panel)* and hPL *(right panel)* secretion by 10 ng/ml EGF or of hCG secretion *(middle panel)* by 1 mmol/L 8-bromo-cAMP/1 mmol/L theophylline of partial hydatidiform moles compared with controls. Mean ± SEM of responders appears in Table I. Responders were defined as having integrated hormone secretion over 7 culture days (EGF) or 3 culture days (8-bromo-cAMP/theophylline) that was significantly greater than control (see Material and methods). Each individual experiment (placenta) had significantly greater responses to stimuli than its own control. *Day of culture*, Culture day after EGF or 8-bromo-cAMP/theophylline was received.

first-trimester placenta secreted 3.59 ± 1.41 ng/ml hCG and 8.23 ± 3.26 ng/ml hPL, with an hPL/hCG ratio of 3.46 ± 0.55. The differences between partial moles and normal placenta were not significant.

The gestational age of all partial moles (14.3 ± 2.0 weeks, mean ± SEM, $n = 9$) was significantly greater than that of all normal placentas (10.0 ± 0.5 weeks, $n = 19$) by analysis of variance ($p < 0.01$). The two complete moles had gestational ages of 12.7 and 16.7 weeks. The age of one partial mole was unknown. The possible effect of gestational age on partial mole and normal placenta responses to 8-bromo-cAMP/theophylline and EGF stimulation was determined in two analyses, shown in Table II. Comparison of the gestational age of partial mole responders with partial mole nonresponders showed no significant difference (Table II). The same comparison showed no differences in the normal placenta group (Table II). The data were also analyzed by comparing partial mole responders and nonresponders with normal placenta responders and nonresponders, respectively (Table II). Although the gestational age of partial moles tended to be greater in all groups, only two comparisons showed statistical significance; 8-bromo-cAMP/theophylline responders were older in the partial mole group, and hPL nonresponders to EGF were also older in the partial mole group.

Comment

In the current study partial hydatidiform moles lacked response of hCG and hPL secretion to EGF stimulation and lacked a secretory response of hCG to 8-bromo-cAMP/theophylline. Partial moles thus showed a failure to develop differentiated function under EGF stimulation or to respond to 8-bromo-cAMP, a known secretagogue of hCG.[18] Complete moles showed a mixed response to these stimuli, but too few were available for statistical analysis. Few previous data in first-trimester placentas are available for comparison. Barnea et al.[17] showed that EGF induces rapid hCG release in a superfusion system and in static cultures but did not note morphologic differentiation. In term placentas we[14] and others[19] have found that EGF induces differentiated trophoblast function, that is, hCG and hPL secretion, and we have determined that the mechanism was due to differentiation of the cytotrophoblast into syncytium.[14] Thus most of the partial moles tested apparently lacked the ability to develop either a secretagogue response or possible morphologic differentiation after EGF exposure. It is unknown if this is due to EGF receptor deficiency or postreceptor events; further studies will be required to determine the mechanisms accounting for the defective response. In partial moles it is unknown why focal hyperplasia occurs. Because the hyperplasia is largely syncytial, the lack of an EGF response is consistent with uncontrolled proliferation. Differentiation ultimately occurs in partial moles; therefore factors other than EGF must be dominant in producing the hyperplasia. Such factors are currently unknown.

It is not clear why not all normal placentas responded to EGF or 8-bromo-cAMP/theophylline, but we pre-

sume this relates to tissue quality. Cell viability of preparations was not a factor because both normal and molar tissue had >95% viability by nigrosine dye exclusion.

In addition to a lack of EGF responsiveness, moles have demonstrated a variety of other hormonal abnormalities including low β-hCG/pregnancy-specific β_1-glycoprotein ratios in both partial and complete moles[10] and low prolactin (partial or complete mole not stated).[9] Complete moles and choriocarcinomas have high free α-subunit and free β-subunit production.[11, 12] The careful study by Berkowitz et al.[13] showed that both complete and partial moles had higher free α-subunit and higher free β-subunit levels than normal placentas. However, partial moles demonstrated higher free α-subunit levels in comparison with those of complete moles, and complete moles had higher free β-subunit levels than partial moles.

Consistently high hCG production has always been assumed to be proportional to increased tissue mass.[20] Our studies (Table I) indicate that the relative responsiveness of partial mole tissue to stimuli, and the hormone produced per cell, is not different from that of normal placenta, confirming this assumption. It is of interest that some studies have noted that hPL levels are lower in molar pregnancy,[6, 9] but we did not find this to be true in cultured cells, wherein the hPL/hCG ratios were similar. The reason for this discrepancy is not known.

We determined the effect of gestational age on the response to 8-bromo-cAMP/theophylline and EGF stimulation of hCG and hPL, because placentas of different ages may have responded differently (Table II). We observed that there was no difference in age between responders and nonresponders within each group separately (partial moles and normal placentas, Table II). We also analyzed the gestational age of responders compared to nonresponders (Table II). Partial moles tended in all comparisons to be older than normal placentas, but only two comparisons reached statistical significance. If age had affected the results, we would have expected responder moles–normal placentas to have different gestational ages than nonresponder moles–normal placentas. This was not observed. Together, these analyses indicate that the older gestational age of the partial moles could not account for their lack of response to stimuli. Consistent with this conclusion is the observation that the magnitude of response of first-trimester normal placentas to 8-bromo-cAMP/theophylline and EGF (Table I[17]) is similar to that seen in our previous studies of term placenta,[14, 18] implying no age-related alteration in trophoblast responsiveness to stimuli. Further studies would need to be conducted to specifically confirm this.

These studies also demonstrate that the antiserum for oncomodulin is useful as a positive cytotrophoblast marker, and GZ100 antiserum is useful to exclude syncytial contamination of cytotrophoblast preparations. Few such markers are available. It should be noted that the presence of Fc receptors on trophoblast[21] necessitates the use of $F(ab')_2$ fragments of polyclonal antisera

to ensure specificity. Additionally, it is of interest that partial and complete moles and normal placentas had the same pattern of expression of a small set of antigens, as tested in this study.

We conclude that partial moles have impaired differentiated function as represented by hCG and hPL secretion in response to stimulation by EGF and 8-bromo-cAMP/theophylline.

Rapid growth of leiomyoma in patient receiving tamoxifen

P.V. Dilts, Jr., MD,[a] Michael P. Hopkins, MD,[a] Alfred E. Chang, MD,[b] and Robert L. Cody, MD[c]

Ann Arbor, Michigan

A 49-year-old patient with breast cancer had a leiomyoma that rapidly enlarged shortly after she started therapy with tamoxifen. Exploratory laparotomy was necessary to confirm the diagnosis. The rapid growth may have resulted from the estrogen agonist properties of tamoxifen or alternatively by ovarian stimulation resulting in endogenous estrogen production. (Am J Obstet Gynecol 1992;166:167-8.)

Key words: Tamoxifen, leiomyoma

Tamoxifen citrate is a nonsteroidal agent that has demonstrated estrogen agonist and antagonist properties.[1] Its antagonist properties make it a seemingly ideal drug for treatment of patients with breast cancers shown to be positive for estrogen receptors. Recently the recommendation has been made that all low-risk patients with breast cancer undergo adjuvant therapy.[2] This will result in a large number of perimenopausal and postmenopausal women being placed on a regimen of tamoxifen for 3 to 5 years. The gynecologic consequences of such widespread use are unknown because little attention has been given to this aspect of therapy. Previously, only high-risk patients or patients with recurrent disease were treated with tamoxifen. Now, low-risk patients undergoing therapy will live longer and will have a longer time in which side effects can develop. Because of the weak agonist properties of tamoxifen for estrogen-sensitive tissues, unexpected results may ensue from its usage. A patient is described to highlight a possible sensitivity for tamoxifen in a previously stable leiomyoma.

Case report

A 49-year-old woman, gravida 3, para 1, spontaneous abortions 2, with no living children, 5 feet 8½ inches tall, weighing 131 pounds, underwent a right modified radical mastectomy in August 1987 for removal of intraductal breast cancer. She received no further therapy. She was diagnosed in August 1988 with a left intraductal breast cancer and underwent a left modified radical mastectomy. Lymph nodes were negative, and tests for estrogen and progesterone receptors were positive. Because both tumors were estrogen receptor positive, in September 1988 she was started on tamoxifen, 10 mg twice daily, as adjuvant therapy, which the patient states she took as directed (assay is available). Her gynecologic history was unremarkable, and she was reported to have had a normal result of pelvic examination in July 1988 by the attending physician at the referring university hospital, before discovery of the second breast cancer. The patient had a computed tomographic scan of the abdomen performed before mastectomy, and at that time an abnormally thickened gastric wall was reported. It was otherwise normal. Three months after she started tamoxifen, a computed tomographic scan was performed at our institution for follow-up of the previously identified abnormality. The thickened gastric wall was normal; however, a large pelvic tumor, which previously had not been present, was discovered. On this scan she was noted to have a 10 × 15 cm, solid lower abdominal mass. On pelvic examination this filled the pelvis and was somewhat deviated to the right. It could not be distinguished from the uterus. Radioimmunoassay for pregnancy gave negative results, and an ultrasonographic examination revealed a probable leiomyoma with the possibility of a 4 cm cyst in one ovary. Menses had been regular before she started tamoxifen, with the last normal menstrual period on Sept. 4, 1988. She reported spotting for 1 day on Nov. 3, 1988.

At exploratory laparotomy the pelvis was noted to be markedly estrogen stimulated, similar to that seen with a term pregnancy. There was extensive venous engorgement. A total abdominal hysterectomy and bilateral salpingo-oophorectomy were performed. The remainder of the abdomen, including the stomach, was normal. The pathologic findings showed a 380 gm uterus with a benign leiomyoma 7 cm in diameter. The endometrium showed secretory endometrium. One ovary contained a corpus luteum cyst and the other contained a hemorrhagic corpus luteum. The patient had a normal postoperative course and was restarted on the previous dosage of tamoxifen. The patient is currently free of disease 26 months from the time of hysterectomy.

Comment

Tamoxifen competes with estradiol for receptor protein–binding sites. Hot flashes, vaginal discharge, and

irregular menses are the principal side effects of tamoxifen in the woman of reproductive age. All of these symptoms suggest the usual antiestrogenic effects attributed to tamoxifen. This drug does have agonist properties, however, and was originally developed as a fertility agent in the family of clomiphene citrate. In the case reported tamoxifen may have blocked the estrogen receptors in the hypothalamus, leading to an intense output of gonadotropins, which then led to intense ovarian stimulation and ovulation. This would explain the reported findings, consisting of secretory endometrium (evidence that ovulation occurred) and bilateral corpora lutea and enlargement of the leiomyoma. Alternatively, the pelvic organs may have responded to tamoxifen in an unexpected stimulatory fashion. It is possible that tamoxifen was bound to receptor sites on the leiomyoma, providing a greater stimulation than the perimenopausal estrogen level. This direct stimulation could then lead to rapid enlargement of the leiomyoma.

To our knowledge there are no previous reports in the literature concerning leiomyomas increasing in size under the stimulus of tamoxifen. However, it is known that tamoxifen has an apparent affinity for uptake by the endometrium and there is some selective uptake by the corpus luteum. Thus, in perimenopausal or postmenopausal patients in whom leiomyomas are expected to decrease in size after menopause and loss of estrogen, there may be a direct stimulatory effect by the action of tamoxifen. One report indicates no change in size of leiomyomas in six women receiving 20 mg tamoxifen per day.[3]

Surgical exploration was necessary in this patient because of the rapid growth of a new pelvic mass. The preoperative diagnosis included metastatic breast cancer, a primary ovarian tumor, leiomyosarcoma, or an enlarging leiomyoma, with this being the most likely diagnosis.

Until further cases are reported, it would seem prudent to advise all women who are to be treated with tamoxifen for breast malignancy to have a pelvic examination before such treatment. An initial follow-up examination could then be performed 3 to 6 months after tamoxifen is begun for those thought to have a leiomyoma and then annually to ensure that uterine size remains stable. Abnormal bleeding may also be a result of tamoxifen stimulation, and endometrial biopsy may be necessary in these patients should abnormal bleeding occur. Surgical exploration for enlarging leiomyoma will still be necessary to ensure that malignancy is not present, but the preoperative diagnoses will be less alarming.

Transient severe unilateral and subsequent bilateral primary fetal hydrothorax with spontaneous resolution at 34 weeks' gestation associated with normal neonatal outcome

David M. Sherer, MD, Jacques S. Abramowicz, MD, Paula C. Eggers, RDMS, and James R. Woods, Jr., MD

Rochester, New York

Unilateral primary fetal hydrothorax with spontaneous resolution is a rare occurrence. We present a case in which severe unilateral primary fetal hydrothorax was visualized at 28 weeks' gestation. Two weeks later bilateral primary fetal hydrothorax was documented. Ultrasonographic follow-up demonstrated further dynamic changes in the fetal condition, with an isolated unilateral hydrothorax 1 week later and subsequent complete resolution at 34 weeks' gestation. Delivery resulted in a normal neonate with no signs of pulmonary hypoplasia. (Am J Obstet Gynecol 1992;166:169-70.)

Key words: Unilateral fetal hydrothorax, spontaneous resolution

Fetal pleural effusions are either primary or secondary. Primary effusions are usually chylous, as opposed to secondary collections, which are more often associated with overall fluid retention seen with nonimmune fetal hydrops.[1] The incidence of primary fetal hydrothorax is estimated at one case per 15,000 pregnancies.[1] In the past only three cases of primary fetal hydrothorax with spontaneous resolution have been reported.[1] The following case describes a fetus with severe unilateral pleural effusion at 28 weeks' gestation, which then became bilateral and resolved spontaneously at 34 weeks with normal neonatal outcome.

Case report

A 20-year-old woman, gravida 2, para 0, was seen for her first antenatal visit at 21 weeks' gestation when she presented with spotting. At that time fundal height was S + 21 cm. Laboratory results were: hematocrit 32%, blood type B, Rh positive, negative antibody screen, and Venereal Disease Research Laboratory test and human immunodeficiency virus negative. Ultrasonographic examination revealed a singleton fetus with normal fetal anatomy and a composite gestational age of 21 weeks 4 days. Placental location was posterior, midheight, with no signs of abruptio placentae. At 28 weeks 3 days, repeat ultrasonography performed to document fetal growth disclosed a massive right unilateral primary fetal hydrothorax (Fig. 1). The ratio of lung span to hemithorax diameter was 0.46.[2] No signs of fetal hydrops were noted and a complete fetal echocardiogram was normal, apart from a mild pericardial effusion within normal limits (Fig. 1, *B*). Genetic amniocentesis was performed and subsequently showed a normal 46,XX karyotype. Further workup for nonimmune hydrops, which included maternal testing for α-thalassemia, glucose-6-phosphatase dehydrogenase deficiency, and a Kleihauer-Betke test, failed to disclose a possible cause of the fetal hydrothorax. Venereal Disease Research Laboratory, TORCH, (toxoplasmosis, rubella, cytomegalovirus, and herpes simplex) and parvovirus titers were negative. Repeated detailed ultrasonography did not disclose any further fetal anomalies. Follow-up ultrasonography at 30 weeks 5 days' gestation demonstrated bilateral hydrothorax (Fig. 2, *A*), again without any other signs of fetal hydrops. Because of this dynamic development and anticipation that preterm delivery might be indicated if fetal hydrops were to appear, 12.5 mg intramuscular betamethasone was administered twice to enhance fetal pulmonary maturation, and weekly ultrasonographic follow-up was initiated. At 31 weeks 2 days' gestation the hydrothorax was notable only on the right. This accumulation of fluid markedly decreased at 32 weeks 4 days and at 34 weeks 1 day had completely resolved (Fig. 2, *B*). Subsequent weekly ultrasonographic studies remained unchanged. At 36 weeks induction of labor was performed because of severe oligohydramnios. The patient was delivered vaginally of a female infant weighing 2440 gm with Apgar scores of 9 and 9 at 1 and 5 minutes, respectively. Umbilical artery blood gas values were pH 7.35, P_{O_2} 25 mm Hg, P_{CO_2} 43 mg, oxygen saturation 51%, and base excess −2 mEq/L. Neonatal examination revealed a completely healthy infant with normal chest roentgenogram and electrocardiogram. Both mother and infant were discharged in good health on postpartum day 3.

Comment

Large persistent pleural effusions may prevent normal lung development. Crucial factors in the development of pulmonary hypoplasia are time of onset, severity, and duration of pleural effusions.[1] Our case is unique in that serial ultrasonographic examinations documented late midtrimester, severe, unilateral primary fetal hydrothorax with later bilateral involvement finally resolving at 34 weeks. In the absence of fetal structural or chromosomal anomalies or immune or nonimmune fetal hydrops, the cause of transient pleural effusions is generally unknown. However, one may speculate that intermittent mild fetal cardiac failure may have precipitated this event. Undetected causes could include brief fetal cardiac arrhythmias, transient fetal hypoalbuminemia with associated low colloid osmotic pressure, or an undiagnosed fetal infection. In the presence of intact membranes and the subsequent delivery of an appropriate-for-gestational-age, nonhypoxic, nonacidotic infant, the cause of the oligohydramnios is unclear. It is doubtful whether the oligohydramnios and pleural effusions were related.

Castillo et al.[2] recently noted a lung span–to–hemithorax diameter ratio of 0.44 to 0.77 (mean 0.60) to be uniformly associated with pulmonary hypoplasia. Our case stresses the inability to predict pulmonary hypoplasia on the basis of these ultrasonographic indices alone in cases in which dynamic amounts of fluid collection and lung compression occur. Clearly emphasized is the importance of two main pathophysiologic factors underlying pulmonary hypoplasia, namely, the time of onset and the duration of this insult. We believe that the late onset, beyond 20 weeks' gestation, and limited duration of the fetal hydrothorax in our case contributed to the successful outcome.

Meconium aspiration syndrome: Reflections on a murky subject

Vern L. Katz, MD, and Watson A. Bowes, Jr., MD
Chapel Hill, North Carolina

Meconium-stained amniotic fluid occurs in approximately 12% of live births. In approximately one third of these infants meconium is present below the vocal cords. However, meconium aspiration syndrome develops in only 2 of every 1000 live-born infants. Ninety-five percent of infants with inhaled meconium clear the lungs spontaneously. Recent investigations have suggested that a reexamination of our assumptions about the etiology of meconium aspiration syndrome is in order. Several authors have provided evidence that support the hypothesis that it is not the inhaled meconium which produces the primary pathologic condition of meconium aspiration syndrome but rather it is fetal asphyxia that is the etiologic agent. Asphyxia in utero produces pulmonary vasospasm and hyperreactivity of the pulmonary vessels. With severe asphyxia the fetal lungs undergo pulmonary vascular damage with pulmonary hypertension. The damaged lungs are then unable to clear the meconium. In the most severe cases there is right-to-left shunting and persistent fetal circulation with subsequent fetal death. The incidence of meconium aspiration may thus be essentially unaffected by current obstetric and pediatric interventions at birth. For the asphyxiated or distressed infant we recommend suctioning at birth and tracheal intubation. In the healthy fetus observation may be sufficient. (Am J Obstet Gynecol 1992;166:171-83.)

Key words: Meconium aspiration, asphyxia, postdates

This review questions three long-standing assumptions about meconium. The first is that the presence of meconium in the amniotic fluid is an independent marker of fetal distress. The second is that meconium aspiration primarily occurs when the fetus gasps at birth or in utero, in response to severe asphyxia. The third is that meconium aspiration syndrome is a result of the deleterious effect of the inhaled meconium on the neonatal lungs.

Generations of clinicians have cared for infants dying of respiratory causes after being born through meconium-stained fluid. Our assumptions about meconium aspiration are based on a cause-and-effect relationship derived from such patients. These assumptions link the inhalation of meconium and subsequent severe respiratory distress. When "pea soup" meconium is noted during labor and the nasopharynx and trachea are suctioned, the clinician feels relief and satisfaction if the infant subsequently does well. However, a review of recent reports questions whether the respiratory disease of meconium aspiration syndrome is caused simply by the aspiration of meconium. The clinician who has appropriately managed a case of an infant with meconium has most likely obtained a favorable outcome, not by suctioning the nasopharynx but by avoiding perinatal asphyxia.

Meconium passage

Several studies have examined meconium passage. In the largest series meconium was found in the amniotic fluid of approximately 21,500 of 177,000 live births.[1] The Collaborative Perinatal Project documented a slightly lower incidence of 10.3%,[2] because stained membranes rather than discolored amniotic fluid were counted. Meconium staining of the amniotic membranes begins 1 to 3 hours after the fetus passes meconium.[3] Various series (Table I) have noted incidences between 7% and 22% of live births.[1, 2, 4-20] Meconium passage is rare before 38 weeks but occurs more than 30% of the time in pregnancies >42 weeks' gestation.[6-8, 20-24] Green discoloration of amniotic fluid is found in 1% to 3% of second-trimester amniocentesis

procedures.[25-27] This discolored fluid has been noted to contain multiple hemoglobin breakdown products.[25, 26] Table II summarizes series that have examined meconium passage as a function of gestational age.

The hormonal control of fetal meconium passage is maturationally dependent.[28-30] Motilin, an intestinal peptide, is a hormone responsible for bowel peristalsis and defecation.[29] Umbilical cord motilin levels are higher in infants who have passed meconium compared with those in infants with clear amniotic fluid, and motilin levels are lower in premature infants than in term and postterm infants.[29-31]

The neural control of meconium passage is also dependent on gestational age, because maturation and myelination of the neural plexus of the gastrointestional tract progress throughout gestation.[28] As the nervous system matures, parasympathetic stimuli may be propagated and initiate defecation. Under laboratory conditions, when subjected to umbilical cord compression or fetal hypoxia, many near-term fetal animals pass meconium.[32, 33] Thus vagal stimulation, such as from umbilical cord or head compression, will initiate meconium passage only after the innervation of the fetal intestinal tract has matured.

Meconium and fetal distress

The first clinical assumption that many authors have questioned is whether meconium is an independent marker of fetal distress. Obstetrics texts throughout the seventeenth, eighteenth, and nineteenth centuries reported meconium passage as a sign of fetal death or impending death.[34] Several modern studies have examined data collected around the time of birth to correlate meconium passage and fetal distress. Such data must be viewed cautiously because the association of the events of labor and particularly of delivery does not necessarily represent the intrauterine environment at the time of meconium passage. For example, analysis of Apgar scores to correlate distress with meconium-stained fluid may be misleading, because Apgar scores are affected by tracheal intubation. Blood gas analyses may be more accurate indicators of fetal well-being. For meconium to be an independent marker of fetal distress, infants with meconium staining would have adverse perinatal outcomes without other evidence of fetal compromise. This has not been found to be the case.

Table III summarizes studies that have examined the relationship between meconium and fetal distress. In general, when normal fetal heart rate (FHR) patterns are found with meconium-stained fluid, the neonatal outcome is similar to that of neonates with clear fluid.[11, 16, 24, 35-41] Similarly, when infants with meconium have antepartum signs of distress, such as fetal tachycardia, decreased FHR variability, and the absence of accelerations, the neonatal outcomes are similar to those of non-meconium-stained infants with similar FHR abnormalities.[11, 36, 38, 42, 43] Among infants in the Collaborative Perinatal Project the incidence of meco-

nium in the amniotic fluid was similar in asphyxiated and nonasphyxiated infants.[41] Thus meconium is not an independent marker of fetal distress but rather a result of an event, such as cord compression, and often an environment, such as decreased amniotic fluid, that may predispose to or be a consequence of fetal compromise. Some fetuses with meconium-stained fluid will be compromised, but most will not. As Miller et al.[35] have stated, "the presence of meconium in the amniotic fluid without signs of fetal asphyxia . . . is not a sign of fetal distress . . . ."

Meconium aspiration

The second assumption is that meconium aspiration is primarily a consequence of a fetal gasping at birth. Meconium aspiration may be defined as the presence of meconium below the vocal cords (as opposed to meconium in the oropharnyx). Meconium is found below the vocal cords in 11% to 58% (mean 35%) of live births with meconium-stained amniotic fluid, approximately 4% of all live births (Table IV).[11, 13, 15, 18, 40, 43-45] Meconium may pass through the trachea and into the lungs through two related mechanisms, gasping and deep breathing.

Fetal gasping is a normal response to asphyxia. The asphyxia may vary from a mild increase in carbon dioxide to severe acidemia and may represent temporary umbilical cord occlusion or profound metabolic acidosis.[32, 33, 46] Dawes et al.[32] induced meconium aspiration in fetal lambs with umbilical cord occlusion. The fetal lambs passed meconium, gasped, and inhaled the meconium into their lungs. When the occlusion was relieved, amniotic fluid and meconium passed out of the fetal lungs. Gasping has been induced in rhesus monkeys and baboons.[47, 48] Block et al.[47] produced meconium aspiration after placing meconium in amniotic fluid of pregnant baboons and then occluding the maternal aorta.

Human gasping has been described in high-risk fetuses 24 to 72 hours before intrauterine death.[49] Amniotic fluid, cellular debris, and meconium may be found in the lungs of fetuses who have died in utero of asphyxia.[50, 51] Autopsies of severely asphyxiated preterm stillborn fetuses consistently demonstrate amniotic fluid and debris in the fetal lung parenchyma, but meconium is rarely found.[51, 52] This is because meconium is seldom present in the amniotic fluid of preterm infants.

Fetuses also aspirate meconium and amniotic fluid by deep (irregular) breaths in utero. The net flow of fluid is out of the fetal lungs into the amniotic cavity with the shallow, regular thoracic motion that constitutes 90% of fetal "respirations".[32, 33, 49, 53] Shallow, regular "breathing" may demonstrate some forward and backward flow. However, Dawes et al.[32] found repetitive

periods in which the fetus made "relatively deep inspiratory efforts" in unasphyxiated animals. These deep inspiratory efforts were seen more frequently as gestation advanced and represented up to 10% of all fetal "breathing." This normal deep breathing may account for some of the meconium that is inhaled in utero. Thus meconium below the vocal cords may be related to the concentration of meconium, as well as to the duration of meconium exposure.

In nonasphyxiated, nonhypoxic human fetuses, regular passage of amniotic fluid deep into the fetal lung is well documented. Injection of radiopaque contrast medium into amniotic fluid has produced images of the fetal lungs in utero.[38] Duenhoelter and Pritchard,[54] injected chromium 51–labeled red blood cells intraamniotically. The red blood cells were found only deep in the fetal lung parenchyma and in the stomach in both abortuses and fetal rhesus monkeys that were exposed to the red blood cells for 24 hours. To show that the chromium-labeled cells were not inhaled immediately before delivery, iron 59–labeled red blood cells were also injected into the amniotic fluid shortly before delivery. There were many chromium-labeled cells but few iron-labeled cells deep in the fetal lungs. In their studies Duenhoelter and Pritchard showed that human fetuses as well as rhesus monkey fetuses, inhale approximately 200 ml/kg/24 hours.

Fetal hypercarbia will increase the incidence of deep breathing.[53] An increase in the P_{CO_2} of as little as 5 mm Hg may induce increased deep breathing.[55] This level of hypercarbia without asphyxia can occur from transient umbilical cord compression.[32, 48, 53] Martin et al.[48] demonstrated deep breaths concurrently with variable

decelerations in rhesus monkeys. Other investigators[32, 33, 53] have produced gasping with umbilical cord occlusion. Such umbilical cord occlusion may not be sufficiently prolonged to induce fetal distress, manifested as acidemia, yet may increase P_{CO_2}, which results in deep respirations that draw meconium into the lungs. Although hypoxia decreases breathing motion, hypoxia and hypercarbia act synergistically to stimulate gasping.[56]

Several investigations[11, 13, 15, 43, 44] have examined the status of infants with meconium below the vocal cords (Table IV). The finding of meconium below the cord is rarely a consequence of severe fetal compromise. However, there is a subgroup of infants with meconium below the cords who will be severely distressed. Dooley et al.[44] analyzed 272 births of infants with meconium-stained fluid. Meconium was found below the cords in 21% of these infants. When the groups with and without meconium below the cords were compared, there was no difference in gestational age, birth weight, umbilical cord pH, P_{CO_2}, P_{O_2}, base deficit, percent of infants with pH <7.2, or base deficit >5 mEq/ml. In a study by Yeomans et al.[43] of meconium-stained infants, among a group of infants with meconium below the vocal cords, 69% had an umbilical artery pH >7.19. Eleven percent of infants in the study of Yeomans et al. had an umbilical cord pH <7.15, corresponding to the infants who may aspirate as a secondary result of severe asphyxic stress. Five percent of infants had low umbilical cord pH and did not have meconium below the vocal cords.

In a study of 238 births with meconium-stained amniotic fluid, Rossi et al.[11] found meconium below the cords more commonly in the presence of thick meco-

nium. This finding agrees with the theory that the greater the concentration of meconium in the amniotic fluid, the more meconium will pass transtracheally.

Timing of meconium aspiration

In the 1970s through the late 1980s, many authors[12, 18, 22, 35] felt that meconium was aspirated with the infant's first breath. This concept arose from an influential experiment by Gooding et al.[57] in which puppies could not be induced to aspirate meconium until it was injected below the vocal cords before the puppies' first breath.

Carson et al.[12] advocated oral DeLee tube suction by the obstetrician followed by tracheal intubation and suction of meconium by the pediatrician, all before an infant's first breath. In a retrospective review they found five deaths in 18 cases of meconium aspiration syndrome without combined suction and no deaths among seven cases of meconium aspiration syndrome after the institution of the combined suction protocol. Their conclusion was that because aspiration occurred with the first breath, clearing the airway decreased the severity of meconium aspiration syndrome. When other investigations confirmed the findings of Carson et al., the concept of meconium aspiration occurring with the infant's first breath was established.[18, 22, 45]

Within a few years of the work of Carson et al., several reports emerged that questioned this concept of meconium aspiration. Meconium was found below the vocal cords in fetuses dying in utero and in infants before their first breath. Severe disease developed in spite of suction at delivery (Table IV).[7, 11, 13, 15, 18, 19, 40, 43-45, 50, 51] Falciglia,[15] in reviewing a series of 4896 deliveries, concluded: "Our findings suggest that meconium aspiration is predominantly an intrauterine event." The aspiration of amniotic fluid is not only an intrauterine event but also an antepartum process. In the fetus with oligohydramnios and cord compressions, meconium aspiration will continue during labor, with continued fetal gasping.

Meconium aspiration syndrome

The third assumption that recent investigations have focused on is that the pathologic condition of meconium aspiration syndrome is primarily a result of the injurious effects of meconium on the fetal and neonatal lungs. A review of the clinical findings in meconium aspiration syndrome suggests that parenchymal lung damage or airway obstruction from inspired meconium is not the primary cause of the pathophysiologic condition.

Meconium aspiration syndrome represents a wide spectrum of clinical disease. Mild transient distress in the setting of meconium-stained amniotic fluid, without the need for treatment, has been labeled "subclinical meconium aspiration syndrome."[5] Respiratory distress

with minimal oxygen requirements (<40%) for <48 hours is considered mild disease.[11] Respiratory distress lasting for >48 hours with an oxygen requirement necessitating mechanical ventilation is usually defined as severe disease.[11] Meconium aspiration syndrome is fatal in up to 40% of cases (Table I); the percentage varies with the extent to which mild aspiration syndrome is included in the diagnosis. Almost all disease is manifest within the first few hours of birth, and severe disease is often manifest from the time of delivery. Fatal meconium aspiration syndrome may occur within minutes of birth.[19, 50, 58, 59]

The radiographic findings of the chest x-ray film are specific and diagnostic for meconium aspiration syndrome.[60] These findings include coarse and patchy areas of decreased aeration, areas of widespread consolidation or infiltrates, and occasional areas of increased aeration.[60] Small pleural effusions occur in up to one third of infants. Air leaks represented by pneumothoraces and pneumomediastinum occur in up to one quarter of all infants.[1, 11, 18, 22, 60-63] When sequential radiographs are obtained during the course of the disease, labeled meconium can be seen to migrate into the lung parenchyma over the first 4 hours after birth.[57, 60, 64] Areas of diminished aeration clear within 24 hours, and 80% of all x-ray films are clear within 48 hours.

Forty percent to 73% of infants born with meconium-stained fluid have positive chest x-ray findings, although fewer than half of these infants show signs of respiratory distress.[18, 45, 60] In addition, the severity of x-ray findings may not always correlate with the clinical disease. Some infants may experience severe disease with minimal x-ray findings, while other infants have remarkable x-ray findings without clinical disease.[18, 65]

Hypoxia is the primary clinical problem for infants with meconium aspiration syndrome. The hypoxia may be mild or profound. Profound hypoxia is usually secondary to right-to-left shunting.[62, 63, 65-69] Measurement of oxygen saturation during ventilation with 100% oxygen demonstrates shunting of varying degrees.[66, 69] In one study shunts from 27% to 73% were documented.[65] Severe meconium aspiration syndrome is associated with pulmonary hypertension and persistent fetal circulation, with a patent ductus arteriosus and patent foramen ovale.[1, 6-8, 11, 13, 15, 19, 44, 50, 51, 52, 59, 61-69] Neonatal cardiac catheterization in infants with meconium aspiration syndrome has demonstrated high right ventricular and pulmonary artery pressures equal to or exceeding systemic arterial pressures.[66]

Autopsy findings include meconium, vernix, fetal squamous cells, and cellular debris at different levels in the lungs from the small airways deep into the alveoli. Meconium may obstruct some airways.[19, 51, 58, 59, 70] Occasionally, minimal meconium or no meconium will be found in the lungs, although the clinical disease mimics classic meconium aspiration syndrome.[19, 71] The inflammatory response to meconium may appear as consolidation and pneumonia with polymorphonuclear leukocytes, macrophages, and edema. However, large quantities of meconium with wide distribution are often found deep in the lungs without histologic signs of inflammation.[70] Hyaline membranes are frequently seen in infants surviving for >24 hours.[70, 72] In one autopsy series of postmature infants, 18 of 21 infants had hyaline membrane disease and 17 of these 18 died of meconium aspiration syndrome.[72]

Pathologic conditions in the pulmonary vasculature of infants dying of meconium aspiration syndrome include diffuse and severe pulmonary hemorrhage and necrosis of pulmonary vessels and pulmonary parenchyma.[19, 58, 59, 71, 73] Platelet-rich microthrombi in small arterioles have also been noted.[74] Muscularization in the distal pulmonary vasculature has been found in severe meconium aspiration syndrome.[70, 75-77] Ordinarily, muscular pulmonary vessels course together with the airways and extend to the level of the terminal bronchioles.[63, 69, 75-77] Less than 20% of pulmonary vessels traversing along the respiratory bronchioles have identifiable smooth muscle. However, many infants dying of meconium aspiration syndrome, whose clinical course is characterized by persistent pulmonary hypertension, have muscularity of the small vessels extending to the distal arterioles and into the vessels surrounding the alveoli.[63, 67, 70, 75-77] Perlman et al.[70] found muscularization not only in stillborn infants and neonates dying of meconium aspiration but also in stillborn infants dying of abruptio placentae. Excessive muscularization takes 3 to 7 days to develop in utero and has been reproduced in animals by fetal exposure to hypoxia.[77-81]

The theory of meconium aspiration syndrome in question is that the pathologic characteristics of the disease are primarily a result of the effects of meconium on the lung parenchyma. This theory does not account for the following: (1) 35% of infants born with meconium in the amniotic fluid will have meconium in the lungs, with up to 55% of all meconium-stained infants having abnormal chest x-ray findings, yet respiratory distress develops in only 5% to 10% of infants with meconium below the vocal cords; (2) some infants die in utero or within the first hour of life, with histologic evidence of meconium aspiration; (3) clinical disease may occur in some cases without signs of inflammation, occasionally with no meconium at all found below the vocal cords.

Etiology of meconium aspiration syndrome

Recent investigations have advanced the hypothesis that the respiratory distress and hypoxia of meconium

aspiration syndrome are initiated by pulmonary vascular disease. The pathophysiologic changes are vascular spasm and vascular hyperreactivity of the pulmonary vessels. In mild cases the vascular disease is a transient, reversible hyperreactivity manifest as brief episodes of desaturation.[61, 62, 68] In the most severe cases of meconium aspiration syndrome, the pulmonary vascular disease is a fixed pulmonary hypertension with persistent fetal circulation and pulmonary vascular necrosis and hemorrhage.[63, 65, 67, 72] The normal transition from fetal to adult circulation, from pulmonary vasoconstriction to pulmonary vasodilatation, is profoundly disrupted in infants with severe meconium aspiration syndrome.[63, 77, 78, 81] The cause of the pulmonary vascular spasm, is fetal hypoxia and asphyxia.[61, 62, 63, 66, 70, 77, 82, 83] Meconium inhaled below the vocal cords in an unasphyxiated infant produces only a mild, benign, self-limited respiratory challenge that is asymptomatic >90% of the time.[11, 15, 44] Meconium aspiration syndrome is a multifaceted disease. Antenatal asphyxia is the primary problem that injures the lungs. Meconium may compound the insult by causing localized areas of pulmonary hypoxia, as well as a chemical pneumonitis. Infection also may contribute to the pathophysiologic condition by further inducing pulmonary vasospasm and by injuring the alveoli.

The normal fetal pulmonary vasculature remains constricted until birth. With the transition to an extrauterine environment, the sudden increase in the size of the pulmonary vascular bed causes an abrupt fall in pulmonary arterial pressure.[67, 78] Pulmonary circulation increases within 1 minute from 10% of the cardiac output to 50%.[67, 80] The muscular arteries in the proximal pulmonary arterial circulation undergo a shrinkage in wall thickness and contractile cells over the next 3 to 4 days. Although the complete mechanism of pulmonary vasorelaxation is unknown, increasing P_{O_2} and expansion and inflation of the lungs at birth, as well as humoral factors, are involved.[67-69, 75, 77, 78, 83, 84] In contrast, hypoxia produces vasoconstriction in both the fetal and the neonatal pulmonary circulation.[67-69, 77, 78, 83]

In the newborn the pulmonary vascular response to hypoxia is dependent on both the age of the infant and previous hypoxic exposures. In the infant who has progressed beyond the first week and in the adult, hypoxia produces increased pulmonary artery pressures.[85] However, the increase in pulmonary artery pressure is always less than the systemic arterial pressures. In contrast, in the fetus and very young newborn, hypoxia can produce a rise in pulmonary artery pressure that is greater than the systemic artery pressure.[85] Clinically, such an increase in pressure can produce a return to the fetal circulation, with shunting of blood from the right side of the circulation to the left side with a precipitate decrease in oxygen saturation. In this way the newborn response to hypoxia is different than that of older infants or adults.[85, 86]

The critical factor that influences the response of a newborn to hypoxia is the prior exposure of the fetus to a low P_{O_2}. Hypoxia and asphyxia in utero produce a pulmonary vasoreactivity that lasts well into the newborn period.[61, 62, 75-77] This pulmonary vasoreactivity may cause marked increases in pulmonary artery pressures in response to only minimal changes in oxygen in the newborn. This pulmonary vascular spasm may be "set off" by changes in temperature, stimulation, or any irritation that results in a change in systemic arterial pressures (as well as by hypoxia). Slight hypoxia may set off a vicious cycle in which resulting vasospasm causes worse hypoxia and additional vasospasm.[61, 62, 66-72, 82, 83]

The severity of the vasospasm is dependent on the extent of the fetal hypoxic insult.[68, 78, 82, 83] If the fetal asphyxia was brief and mild, the neonatal pulmonary vasospasm may result in transient shallow declines in oxygen saturation and respond readily to oxygen therapy.[67, 78, 82] If the asphyxia in utero was severe, the pulmonary vasoreactivity may be manifest as a fixed pulmonary hypertension, with extensive right-to-left shunting and histologic findings of muscularization of the most distal pulmonary arterioles.[61-63, 66-73] It is this pulmonary vasohyperreactivity that initiates the pathologic condition of meconium aspiration syndrome. Severe fetal hypoxic insults are rare; thus severe meconium aspiration syndrome is rare, occurring in <2% of infants who pass meconium (approximately 2/1000 live-born infants).[1]

Several investigators have demonstrated the cause-and-effect relationship between fetal asphyxia and neonatal pulmonary vascular disease.[87-92] Drummond and Bissonnette,[87] using placental embolization, produced both pulmonary hypertension and an exaggerated response to hypoxia in newborn lambs. Gersony et al.[88] produced pulmonary hypertension, persistent fetal circulation, and pulmonary vascular spasm in newborn lambs by creating maternal hypotension with aortic occlusion of the pregnant ewes and subsequent decreased placental blood flow. These investigators reproduced in newborn lambs the downward spiral of hypoxia, pulmonary vascular spasm, right-to-left shunt, worsening hypoxia, worsening pulmonary hypertension, and neonatal death seen in meconium aspiration syndrome.[88]

Excess muscularization is the most severe form of pulmonary vascular disease in meconium aspiration syndrome. Experimentally, fetal exposure to hypoxia produces excessive muscularity in pulmonary vessels of rats in 3 to 7 days.[79-81] Newborn pulmonary hypertension may also be produced by the induction of fetal systemic hypertension.[91] In sheep, prolonged fetal arterial hypertension produced by ligation of one renal

artery led to fixed pulmonary hypertension and distal pulmonary vessel muscularization.[91]

One of the most important experiments pertaining to meconium aspiration in the past three decades was performed by Jovanovic and Nguyen,[93] who illustrated the relationship between severe in utero hypoxia and meconium aspiration syndrome.[93] Fetal guinea pigs were exposed to either a pH of 7.10 for 1- and 2-hour periods before delivery or to a pH of 7.10 for 1 hour per day for 2 weeks before delivery, or they were delivered without hypoxic exposure. At the time of delivery, before the first breath, the tracheas of the guinea pig pups were injected with either amniotic fluid or meconium. After 24 hours, in the unasphyxiated guinea pig pups both amniotic fluid and meconium fluid produced only minimal lung parenchymal reaction. However, in the asphyxiated pups there was extensive pulmonary necrosis and diffuse hemorrhage with destruction of alveolar walls. The worse the asphyxia, the greater the degree of pulmonary damage. In the asphyxiated guinea pig pups there was no difference between amniotic fluid and meconium-induced pathologic conditions.[93] As in the severely asphyxiated human fetuses seen in many studies, the type of aspirate, amniotic fluid, or meconium did not acutely affect the severity of the pulmonary disease.[65, 69, 73] The asphyxia was the major element that caused the clinical distress and pathologic damage. Jovanovic and Nguyen[93] concluded "... our results suggest strongly that the extent of lung destruction seen in meconium aspiration syndrome is not related to the aspiration of meconium, but to the length and degree of asphyxia."

Asphyxia may produce pulmonary disease in the newborn through other mechanisms besides pulmonary vascular spasm and vascular hyperreactivity. The reabsorption of fetal lung fluid is critical in the transition from fetal to newborn life. This reabsorption of fluid is dependent on a change in an adenosine triphosphatase–dependent pump in the pulmonary epithelium. This pump may be compromised by asphyxia,[94] and the result would be increased lung fluid and hypoxia. Asphyxia also inhibits capillary flow. Hutchison and Russell[95] demonstrated a 25% reduction in pulmonary capillary blood flow in asphyxiated term infants. As pulmonary capillary blood flow declines, the relative hypoperfusion leads to alveolar damage, which results in injury of type 2 cells, a decrease in surfactant, and atelectasis, producing further hypoxia and the formation of hyaline membranes.[96] The hypoxic damage to the alveolae causes an increase in pulmonary lung permeability and increased lung fluid, which in turn increases hypoxia and leads to right-to-left shunting and the consequent respiratory symptoms.[61, 62, 72, 73, 95]

This question now arises: What is the role of meconium in meconium aspiration syndrome? The presence of meconium in the asphyxiated lung is definitely deleterious, yet in the unasphyxiated lung current evidence suggests that it is rarely harmful. The hypoxia and pulmonary hypoperfusion in the asphyxiated infant impair the normal mechanisms that clear aspirated meconium and amniotic fluid from the lungs. Cilia in the neonatal respiratory tree may be damaged in hypoxia. The meconium that is normally cleared through the pulmonary circulation may remain and induce the chemical pneumonitis that is characteristic of meconium aspiration syndrome.[96] In the alveoli, meconium may act to inhibit and displace surfactant, resulting in atelectasis and hyaline membranes.[72, 97-99] The asphyxiated and injured lung cannot respond well to the insult produced by meconium. Thus asphyxia plus meconium is significantly worse than asphyxia alone. Thibeault et al.[73] studied a group of infants with an initial pH <7.00. Of 14 infants without meconium aspiration, all needed mechanical ventilatory support and four died. Of 25 infants with asphyxia in addition to meconium aspiration, four infants died with persistent fetal circulation. However, among the survivors there was more pulmonary insufficiency, significantly more time on the ventilator, and more respiratory distress than in the infants who were asphyxiated without meconium. Meconium in an injured and severely asphyxiated lung may severely exacerbate the clinical symptoms.

Postdate pregnancies, thick meconium, oligohydramnios, and neonatal disease

The theory that meconium aspiration syndrome is initiated by pulmonary vasoreactivity as a secondary effect of antepartum and neonatal hypoxia helps explain several epidemiologic aspects of meconium aspiration. Among large series of deliveries, respiratory disease rarely develops in infants with meconium but without FHR abnormalities in labor, and the worst disease develops in the infants who are asphyxiated.[11, 15, 19, 64, 100, 101]

The association between postmaturity and meconium passage may be explained by the increased likelihood of cord compression as amniotic fluid declines with advancing gestation, coupled with a more mature fetal intestinal tract.[21, 23, 35, 36, 102-106] Decreasing amniotic fluid volume is a progressive feature of advancing gestation.[8, 16] Druzin and Adams[104] found a 50% incidence of meconium passage in postdate pregnancies with oligohydramnios. Trimmer et al.[105] noted meconium passage in 13% of postdate pregnancies with normal amniotic fluid volume. However, 38% of infants passed meconium in postdate pregnancies with decreased amniotic fluid volume. The decrease in amniotic fluid volume may occur over a matter of 24 hours.[106]

The incidence of meconium aspiration syndrome is increased eightfold in postdate infants in comparison

with term infants, even though the incidence of meconium passage only doubles.[7] The increased incidence of meconium aspiration syndrome with postmaturity is, in part, related to oligohydramnios. Both increased fetal systemic arterial pressure and redistribution of fetal circulation away from the kidneys (and resultant decreased fetal urine output) are a response to hypoxia.[87-90, 92, 104] The decreased urine output results in decreased amniotic fluid and more umbilical cord compression. In one series of pregnancies >42 weeks, 74% of all labors were accompanied by variable decelerations related to cord compressions.[102] Oligohydramnios predisposes to fetal compromise through umbilical cord compression.[102-104] Alternatively, oligohydramnios is in itself a sign of uteroplacental insufficiency.[7, 8, 23, 102, 107, 108]

The consistency of meconium-stained fluid is a product of the amount of meconium passed and the quantity of amniotic fluid in which the meconium is diluted.[6, 8, 13, 16, 21, 23] The less amniotic fluid, the thicker the meconium.[107] In a longitudinal study with amnioscopy, light meconium became thick over time; however, thick meconium did not become thin.[107] Ninety-five percent of meconium aspiration syndrome develops in the presence of thick meconium.[7, 8, 11] Although 5% of meconium aspiration syndrome develops in the presence of thin meconium, the associated respiratory disease is mild.[8, 11]

Meconium aspiration syndrome is particularly severe and often lethal in the presence of infection, because infection may lead to pulmonary hypertension through the direct action of toxins on the pulmonary vasculature.[83, 109] Group B streptococcal exotoxin causes pathologic conditions by the induction of pulmonary vascular spasm. This vascular spasm is mediated through a different pathway than hypoxic vasospasm. Hypoxia and infection may produce compound effects in a logarithmic fashion.[83] Other types of bacteria and viruses have also been associated with pulmonary hypertension.[108, 110, 111] Meconium is also known to inhibit the normal amniotic fluid bacteriostatic qualities, thus promoting bacterial growth.[112] Thus severe or lethal disease may develop in a patient with mild pulmonary insult and meconium inhalation in the presence of infection.[58, 108, 113]

Prevention and treatment

In the period of the late 1950s through the 1960s, when meconium was thought to be a marker of fetal distress, obstetric intervention was called for whenever meconium was noted in the amniotic fluid. In the mid-1970s, authors[114] stated that the presence of meconium was an indication for fetal scalp sampling. Currently, most obstetric protocols call for internal fetal heart monitors in the presence of thick meconium-stained amniotic fluid.[115] Internal monitoring is recommended because of the finding of absent or decreased variability in infants with distress and meconium, patterns more adequately assessed with internal monitors.

In the early 1970s, several investigators thought that meconium aspiration syndrome developed as a result of the infant aspirating meconium with the first breath. Thus protocols were developed calling for nasopharyngeal and oropharyngeal suctioning immediately on delivery of the baby's head, followed by suctioning of the trachea under laryngoscopic visualization by the pediatrician, a "combined approach."[12] If meconium was seen in the trachea, then intubation with subsequent suctioning was advocated. Some authors also advocated routine bronchotracheal saline solution lavage; this is no longer routine.[115]

Although the "combined approach" found widespread acceptance and became the "standard of care," severe disease to develop continued in infants.[10] Many investigators questioned aspects of the combined approach. Hageman et al.[13] found no difference in the clinical outcome of infants with moderate-to-thick meconium who had obstetric suction on the perineum with either the DeLee catheter or a bulb. In 130 infants suctioned by bulb compared with 186 infants suctioned by DeLee catheter, the incidence of meconium below the cords and meconium aspiration syndrome was similar.[13] In addition, respiratory complications developed in three infants from the pediatric suction and tracheal visualization. Locus et al.,[14] in a recent study, also failed to show a superiority between DeLee and bulb suction in removing moderate or thick meconium from the trachea of infants. Falciglia[15] found no difference in the incidence of meconium in the trachea or meconium aspiration syndrome with obstetric suction before or after delivery. Dillard[116] compared the neonatal outcomes of infants not suctioned with those of infants in the series of Gregory et al.,[18] who advocated a combined approach. Dillard found no difference in outcome when infants were not suctioned.

The potential problems of the pediatric aspects of the protocol, DeLee suction and laryngoscopic visualization, were also questioned by a series of reports noting complications. Cordero and Hon[117] studied 46 consecutive neonates who had nasopharyngeal suction. Cardiac arrhythmias developed in seven infants, and five became apneic. Ballard et al.[118] reported a series of eight physicians who were exposed to pathogens from infants' secretions. Organisms ingested by pediatricians included *Neisseria gonorrhoeae,* three cases; herpes simple, one case; varicella, two cases; and *Staphylococcus aureus,* in one. In a survey of pediatricians Ballard et al. found that 74% had ingested secretions during DeLee suction. Van Dyke and Spector[119] reported a case of herpes simplex transmission from pediatrician to

newborn because of suction. Ballard et al.[118] concluded that DeLee suction by mouth was inappropriate and that suction machines should be used.

Further studies did not confirm the original reports of a decrease in the rate of meconium aspiration syndrome or a resolution of the mortality rate after the adoption of the "combined" obstetric-pediatric approach.[1, 4-15, 17, 19] Perinatal advances in the 1970s and 1980s did produce a decrease in the mortality rate of meconium aspiration syndrome. Meconium aspiration syndrome continued to develop in infants in spite of adequate suctioning (Table IV). The explanation as to why the combined approach has been unsuccessful is that meconium is not the primary cause of the pathologic condition of aspiration syndrome; thus removal of meconium does not greatly affect outcome.

With increasing reports of complications from suctioning, as well as questionable efficacy, Linder et al.[17] prospectively studied 572 healthy, unasphyxiated newborns with thick meconium. They compared infants undergoing DeLee suction laryngoscopic visualization and tracheal intubation with infants undergoing DeLee suction only. There were no deaths from meconium aspiration syndrome in either group of infants. In the tracheal visualization group, respiratory complications developed in six infants, meconium aspiration syndrome developed in four, and respiratory complications related to the intubation, stridor, and persistent hoarseness developed in two. In the DeLee-suction-only group, no infant had respiratory complications. The conclusion of the study of Linder et al. was that in healthy newborns laryngoscopic visualization with tracheal suction may be harmful and certainly is not helpful in the prevention of meconium aspiration syndrome. A follow-up review in the *Journal of Pediatrics*[120] concluded that the combined suction protocol should be reevaluated because the etiology of meconium aspiration syndrome may not be associated with the aspiration of meconium, and harm may be done with laryngoscopic visualization.

In a comprehensive study of meconium aspiration syndrome in the armed services from 1973 to 1987, Wiswell et al.[1] showed that there was no change in either the death rate from meconium aspiration syndrome or the incidence of meconium aspiration syndrome for several years after the initiation of a combined obstetric-pediatric protocol in 1973 to 1975. The rate of meconium aspiration syndrome in the period between 1973 and 1976 was lower than at any time until 1985. The death rate in 1975 was also less than the death rate for all years up until 1986. When the years 1973 and 1987 are compared, there was a statistically significant decrease in the incidence of both meconium aspiration syndrome and death from meconium aspiration syndrome. Wiswell et al.[1] stated that although a decrease in the rate of this disease was found, "... these declines were likely influenced by other improvements in perinatal care, which have occurred since the early 1970s. The results do not support that severe meconium aspiration syndrome and resultant deaths can be prevented altogether."

Falciglia[15] stated in 1988 that the rate of meconium aspiration syndrome was similar before and after the incorporation of DeLee and tracheal suctioning. He concluded that meconium aspiration syndrome occurred before birth, and thus the suction was by itself inadequate therapy.

Amnioinfusion is currently being advocated as a treatment for meconium. Sadovsky et al.[121] showed an improvement in arterial cord pH and a reduction in the incidence of meconium below the cords from 29% in 21 fetuses without amnioinfusion to 0% in 9 fetuses with amnioinfusion. Of interest, meconium aspiration syndrome did not occur in either group. In Wenstrom and Parson's study,[122] 36 patients were treated with amnioinfusion and 44 patients were not. Meconium aspiration syndrome developed in three control patients whereas the syndrome did not develop in any infant in the amnioinfusion group. Meconium was present below the cords significantly more frequently in the nonamnioinfusion group. Strong et al.[123] used amnioinfusion in the presence of oligohydramnios and showed a decrease in meconium passage in labor.

Amnioinfusion may help with several of the clinical problems of oligohydramnios. By a decrease in umbilical cord compression there will be less fetal gasping, and by a dilution of the meconium in utero gasping and deep breathing will result in less meconium being inhaled. To assess whether amnioinfusion will decrease the incidence or the severity of meconium aspiration syndrome, large prospective clinical trials will be necessary.[121-123]

Current clinical and experimental data support the theory that meconium aspiration syndrome is a result of intrauterine fetal asphyxia. The best prevention of these conditions is the identification of fetuses who are at risk of asphyxia by means of clinical observation and selective antepartum testing. The postterm pregnancy, as well as other conditions in which oligohydramnios occurs, places patients at particularly high risk for meconium aspiration syndrome. The presence of decreased amniotic fluid in the term and postterm pregnant patient should initiate obstetric intervention. The study of Usher et al.,[7] in which postterm pregnancies were managed with protocols to identify and selectively intervene in cases of oligohydramnios, resulted in no cases of severe meconium aspiration syndrome.

Intrapartum management should include all of the measures that enhance adequate uteroplacental perfusion and reduce the risk of umbilical cord compression. Amnioinfusion in cases of oligohydramnios may be a promising technique for reducing cord compres-

sion, gasping, and intrapartum aspiration of meconium, although additional confirmatory studies are needed. We advocate careful FHR monitoring in the presence of meconium to detect which fetuses may be compromised. Of obvious importance is the timely evaluation of FHR abnormalities that are predictive of fetal asphyxia.

The immediate management of the infant's airway is the most controversial and unsettled matter. It is not clear that the aspiration of meconium before the first breath alleviates in any way the severity of meconium aspiration syndrome; nor is it clear whether any of the methods of removing secretions from the oropharynx and nasopharynx by either obstetrician or pediatrician are effective in preventing or reducing the severity of meconium aspiration syndrome.

Furthermore, there is no convincing evidence that obstetric or immediate neonatal suctioning of the airway to remove meconium improves outcome even in the asphyxiated infant. Clearly, prompt resuscitation and oxygenation are beneficial to such infants. Tracheal intubation and removal of secretions are often necessary to adequately oxygenate the infant. Whether gentle removal of airway secretions, by bulb or DeLee suctioning before delivery of the thorax, reduces neonatal morbidity remains to be shown. Overly vigorous efforts at oropharyngeal or nasopharyngeal suctioning or endotracheal suctioning may be harmful. Local tissue trauma, reflex bradycardia, and delay in providing adequate ventilation are all potential consequences. Well-designed, prospective studies are required to assess the need for and best method of managing the airway of the newly born infant in the presence of meconium-stained amniotic fluid.

Rapid identification of deoxyribonucleic acid sequence differences in cytochrome P-450 21-hydroxylase (CYP21) genes with denaturing gradient gel blots

Richard H. Reindollar, MD, Brian C.J. Su, MD, Steven R. Bayer, MD, and Mark R. Gray, PhD

Boston, Massachusetts

Denaturing gradient gel electrophoresis was used to identify single-base differences in the cytochrome P-450 21-hydroxylase (CYP21) genes of 132 unrelated control individuals and family members of three unrelated patients with 21-hydroxylase deficiency. The salt-wasting variety was caused by gene deletion and gene conversion/deletion mutations in affected members of two families studied. The simple virilizing form, present in the third family, was caused by an apparent point mutation not detectable by routine Southern blots. We have detected many restriction fragment melting polymorphisms in the CYP21 genes of the members of both salt-wasting families and normal individuals with denaturing gradient gel electrophoresis. We also identified a restriction fragment melting polymorphism specific for the simple virilizing patient in the third family. The data demonstrate that the CYP21 genes are highly polymorphic and that denaturing gradient gel electrophoresis is useful for genomic deoxyribonucleic acid analysis of patients with 21-hydroxylase deficiency. (AM J OBSTET GYNECOL 1992;166:184-91.)

Key words: Congenital adrenal hyperplasia, 21-hydroxylase deficiency, denaturing gradient gel electrophoresis

21-Hydroxylase deficiency is the most common cause of congenital adrenal hyperplasia. Classic congenital adrenal hyperplasia is manifested during intrauterine life by varying degrees of aldosterone or cortisol underproduction. Female infants may be adversely affected by masculinization of the external genitalia. Both males and females with the salt-wasting form of 21-hydroxylase deficiency develop sodium depletion and shock after 1 to 2 weeks of life, if left untreated. Prenatal diagnosis and intrauterine treatment of affected female infants will prevent morbidity and mortality associated with this inborn error of metabolism.[1]

Two genes exist for 21-hydroxylation: 21-hydroxylase A (CYP21A) and 21-hydroxylase B (CYP21B).[2, 3] These genes are arranged within the class III region of the histocompatibility complex, in tandem with the two genes coding for the fourth component of complement, C4A and C4B (Fig. 1).[5] Each CYP21 gene consists of 3184 base pairs, differing from each other by 71 bases. Ten of these base pair differences change the protein-coding portion of the sequence.[4, 7] Three deoxyribonucleic acid (DNA) sequence differences in the CYP21A gene disrupt protein translation, making CYP21A a pseudogene. CYP21A and CYP21B have also been called CYP21P and CYP21, respectively, referring to them as the pseudo and active genes.

To date, nearly all of the mutations identified within the 21-hydroxylase genes of patients with congenital adrenal hyperplasia can be attributed to genetic interchange between the CYP21A and CYP21B genes during meiosis.[5, 8-14] Approximately 11% of patients with congenital adrenal hyperplasia have large gene deletions that remove both the CYP21B and C4B genes.[14] Another 11% have large gene conversions in which most of the CYP21B gene sequence has been converted to that of the CYP21A gene.[14] Nearly 76% have point mutations within the CYP21B gene. Many of the point mutations are identical to CYP21A gene mutations.[14]

Only the large gene deletion and conversion mutations are easily identified by routine Southern blotting techniques. These mutations often demonstrate absence of 3.7 kb *Taq* I and 2.9 kb *Kpn* I fragments.[8, 10] Deletions, insertions, and single-base substitutions under 100 base pairs are undetectable on Southern blots,

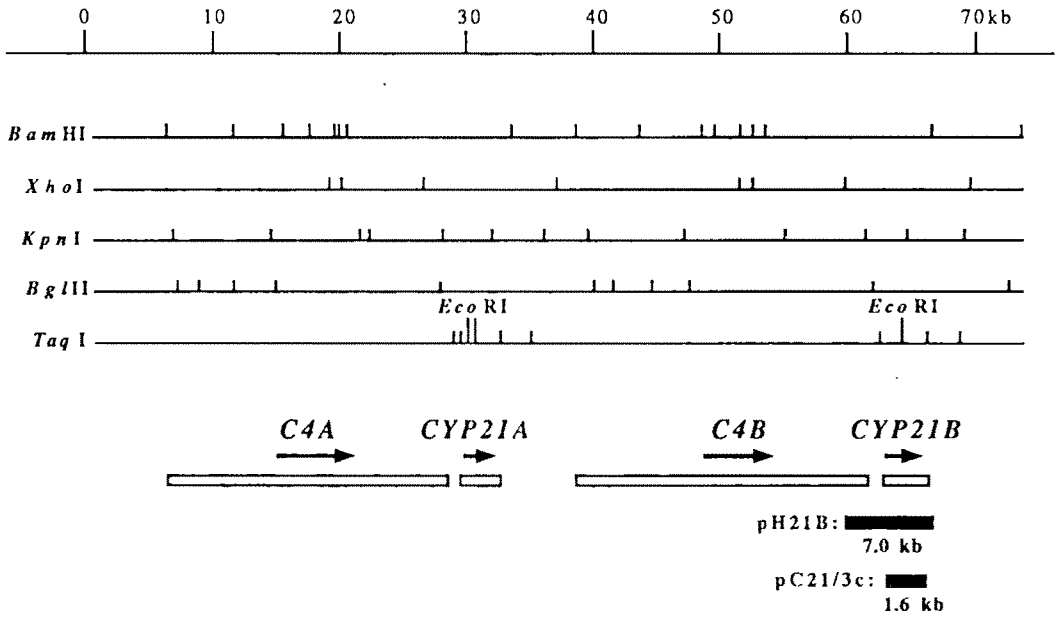

Fig. 1. Structure of CYP21 genes. *Top line* indicates scale in kilobases. Partial restriction map is aligned below scale. Positions of genes at bottom are represented by *open boxes*, with *arrows* indicating direction of transcription. Probes used in experiments are represented by *solid boxes*. This diagram was made with published map and DNA sequence data.[4-6]

unless they change the sequence of certain restriction enzyme recognition sites.[15] The lack of easily identifiable DNA sequence polymorphisms within the 21-hydroxylase genes has limited the use of 21-hydroxylase gene probes for prenatal diagnosis to about 25% of affected chromosomes, by standard Southern blot procedures.[16] Some investigators have suggested that the CYP21 genes are less polymorphic than usual. Consequently, the prenatal diagnosis of congenital adrenal hyperplasia has been made largely by linkage studies that have used DNA probes of closely linked histocompatibility loci.[1, 17]

Denaturing gradient gel electrophoresis can be used to find mutations by detecting small differences in the melting behavior of short (200 to 700 base pairs) DNA fragments.[18] Most DNA fragments subjected to an increasingly denaturing physical environment melt in a discontinuous, stepwise manner, with discrete melting domains of fragments becoming single-stranded in a very narrow range of denaturing conditions. When DNA fragments are electrophoresed in acrylamide gels at high temperatures (60° C) with an increasing gradient of the denaturing solvents formamide and urea, their mobilities sharply decrease as they partially melt, because their shapes become more complex. The denaturant concentration and final gel position, at which a fragment partially melts, are dependent on the DNA sequence of the melted domain. This critical gradient concentration and gel position are often different even when only a single base in the sequence of the melted region is changed. When a mixture of many different fragments is electrophoresed, each will stop at a sequence-dependent position in the denaturing gradient. Fragments containing an A + T–rich domain stop at relatively low denaturant concentrations at a position high on the gel. Conversely, the more stable uniformly G + C–rich fragments usually run to positions low on the gel.

In previous experiments with denaturing gradient gels we physically mapped mutations in the *rosy* locus of *Drosophila melanogaster* to within several hundred base pairs of DNA sequence.[19] The purpose of this study was to apply denaturing gradient gel electrophoresis to identify DNA sequence polymorphisms within the 21-hydroxylase genes of congenital adrenal hyperplasia families and normal control individuals. Because of frequent crossover events between CYP21A and CYP21B genes in normal individuals, it seemed likely that CYP21 gene sequences would be highly polymorphic.[11, 20] Easily detectable polymorphisms would be useful as markers for prenatal diagnosis in the 75% of congenital adrenal hyperplasia chromosomes with point mutations.

Material and methods

This study was approved by the Human Investigational Review Board of New England Medical Center. Informed consent was obtained from all study subjects.

Genomic DNA was extracted from peripheral blood leukocytes with a slightly modified version of a standard method.[6] Samples of 10 ml heparinized blood were mixed with 30 to 35 ml cold cell lysis buffer (0.32

mol/L sucrose, 10 mmol/L Tris hydrochloride [pH 7.5], 5 mmol/L magnesium chloride, and 1% Triton X-100) in 45 ml disposable plastic tubes. Nuclei were pelleted by centrifugation at 2500 revolutions/min for 15 minutes at 4° C. The nuclear pellet was resuspended in 5 ml cold nuclear lysis buffer (75 mmol/L sodium chloride, 24 mmol/L ethylenediaminetetraacetic acid, pH 8.0). Sodium dodecyl sulfate was added to 1% and proteinase K to 100 μg/ml, and the suspension was incubated at 55° C for 1 to 24 hours. The lysate was extracted once in phenol/chloroform (1:1, equilibrated with 0.5 mol/L Tris hydrochloride, pH 8.0), and the DNA was precipitated with isopropanol. The pellet was washed once with 70% ethanol, vacuum dried, and resuspended in TE (10 mmol/L Tris hydrochloride, 1 mmol/L ethylenediaminetetraacetic acid, pH 7.5), at 1 mg/ml. Electrophoresis samples contained 5 to 10 μg of genomic DNA digested in a total volume of 10 to 15 μl. DNA digestions were performed with restriction endonucleases according to the supplier's recommendations.

Digested genomic DNA samples were electrophoresed on 0.8% agarose gels. After pretreatment of the gels, denatured restriction fragments were transferred onto Nytran (Schleicher and Schuell, Keene, N.H.) by Southern blotting.[21] Membranes were vacuum dried at 80° C for 1 to 2 hours.

Denaturing gradient gels were prepared as previously described.[19] The apparatus used for the preparation and electrophoresis of the denaturing gradient gels was designed by Leonard Lerman and purchased from Green Mountain Lab Supply (Waltham, Mass.).[22] All of the denaturing gradient gels were 6.5% acrylamide (37.5:1 acrylamide/bisacrylamide) in TAE buffer (40 mmol/L Tris acetate, 20 mmol/L sodium acetate, 1 mmol/L ethylenediaminetetraacetic acid, pH 7.4). The range of denaturant concentration in the gels was at least 20% to 80% (100% denaturant concentration is 7 mol/L urea and 40% formamide). DNA samples were electrophoresed at 75 to 80 V for 16 to 18 hours at 60° C. Afterward, the gels were stained in ethidium bromide (1 μg/ml) for 5 minutes and examined over a long-wave ultraviolet light source.

The destained denaturing gradient gels were soaked in 0.5 mol/L sodium hydroxide for 5 minutes, 0.5 mol/L Tris, pH 8.0, for 5 minutes, and then in transfer buffer (20 mmol/L Tris, 1 mmol/L ethylenediaminetetraacetic acid, pH 8.0) for at least 5 minutes. Next, each gel was placed in a stack with a nylon hybridization membrane (Nytan), and the stack was inserted into an electrophoretic Western blot transfer apparatus. DNA fragments were transferred by electrophoresis at 600 mA for 2 hours. After electrotransfer, the DNA blots were rinsed briefly in 6× saline sodium citrate buffer (0.15 mol/L sodium chloride, 15 mmol/L sodium citrate, pH 7.4) and baked under a vacuum at 80° C for 1 to 2 hours.

Plasmids containing CYP21B gene inserts were kindly supplied to us by Dr. Perrin White. The plasmid pH21B includes a 7.0 kb *Xho* I/*Bam*HI fragment that contains the entire CYP21B gene and part of the C4B gene as well (Fig. 1).[7] The plasmid pC21/3c contains a 1.6 kb *Bam*HI fragment that includes the CYP21B complementary DNA (Fig. 1).[7] Both insert fragments were excised from their respective plasmids and purified by acrylamide gel electrophoresis. Purified DNA fragments were labeled with phosphorus 32 with the method of primer oligonucleotide extension after hybridization with random primers.[23]

The blots were hybridized as previously described.[19, 24] After hybridization, the blots were washed as follows: (1) 2× saline sodium citrate plus 1% sodium dodecyl sulfate at 22° C for 30 minutes, (2) 1× saline sodium citrate plus 1% sodium dodecyl sulfate at 68° C for 30 minutes, and (3) 0.1× saline sodium citrate plus 1% sodium dodecyl sulfate at 68° C for 30 minutes. Blots were exposed to x-ray film at −70° C in the presence of an intensifying screen for 1 to 10 days.

Results

Study subjects. Control DNA was prepared from peripheral blood leukocytes of 132 unrelated male and female volunteers, not known to have any form of congenital adrenal hyperplasia. A second group of study subjects consisted of members of three families with at least one individual diagnosed with 21-hydroxylase deficiency: families K (n = 3, two generations), T (n = 10, four generations), and M (n = 4, two generations). These three families were selected because they were thought to have at least one of the common types of 21-hydroxylase gene mutations associated with classic congenital adrenal hyperplasia. Salt-wasting 21-hydroxylase deficiency was manifested in affected members of the T and K families and was caused by gene deletion and gene conversion-deletion mutations, respectively. The simple virilizing congenital adrenal hyperplasia manifested by the M family proband was caused by an apparent point mutation.

Southern blot analysis. Genomic DNA from normal and subjects with congenital adrenal hyperplasia was examined for large deletions and chromosomal rearrangements in the 21-hydroxylase genes with Southern blots. Southern blot results were compared with the congenital adrenal hyperplasia classification of Morel et al.[14]

Control subjects. Genomic DNA from all normal individuals tested had the expected CYP21A and CYP21B gene-specific 3.2 and 3.7 kb *Taq* I fragments, respectively, and the CYP21A and CYP21B gene-specific 4.0 and 2.9 kb *Kpn* I fragments, respectively (data

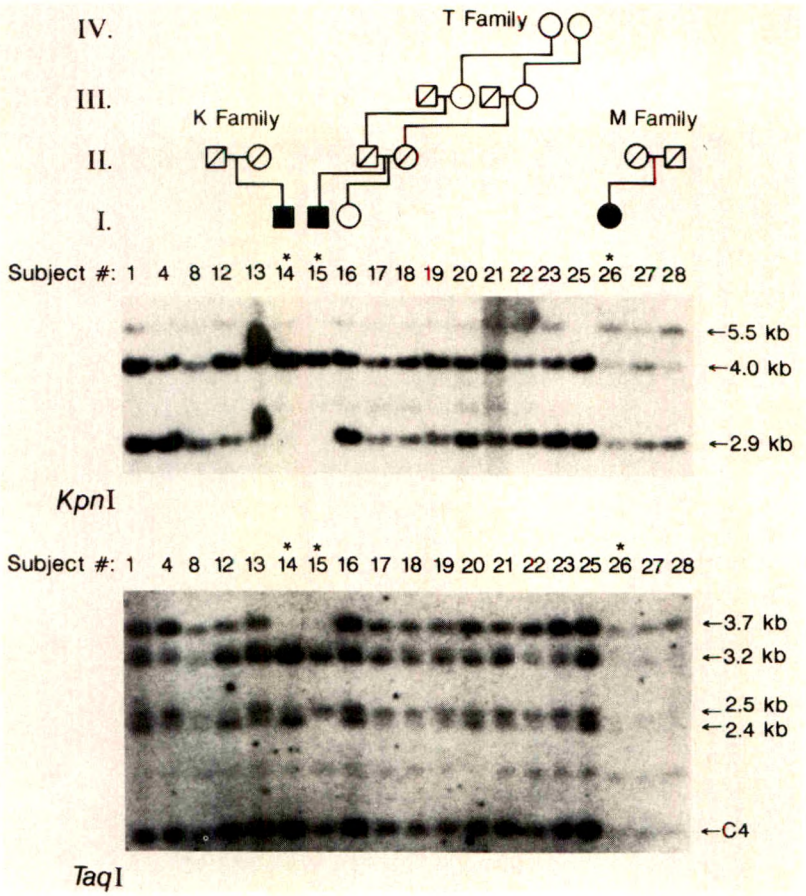

Fig. 2. *Kpn* I and *Taq* I restriction analysis of congenital adrenal hyperplasia pedigrees and controls. *Controls,* Subjects 1, 4, and 8 are control individuals demonstrating the CYP21A 4.0 kb *Kpn* I fragment and 3.2 and 2.5 kb *Taq* I fragments. CYP21B 2.9 kb *Kpn* I fragment and 3.7 and 2.4 kb *Taq* I fragments are also present. *K family,* Affected son is a compound heterozygote for gene conversion and gene deletion mutations. Mutant paternal CYP21 haplotype contains two CYP21A alleles: two copies of 4.0 kb *Kpn* I fragment and 3.2 and 2.4 kb *Taq* I fragments. Mutant maternal CYP21 haplotype is CYP21B gene deletion, with absence of the 2.9 kb *Kpn* I and 3.7 and 2.5 kb *Taq* I fragments. *T family,* Affected son is homozygous for CYP21B gene deletion. All CYP21B fragments are deleted. *M family,* Affected daughter has point mutations not detectable by *Kpn* I and *Taq* I Southern blot analysis.

not shown). The expected downstream CYP21A and CYP21B gene-specific 2.4 and 2.5 kb *Taq* I fragments, as well as the C4 fragment, were present in all normal individuals. Hybridization intensities for the CYP21A and CYP21B gene-specific fragments were approximately equal in most (e.g., Fig. 2, subject 1), but not all (e.g., subject 4), normal individuals. This suggests that unequal copy numbers of the two 21-hydroxylase genes are common among normal individuals. Additionally, because control subjects did not undergo adrenocorticotropin stimulation testing, it is possible that several of these individuals were heterozygote carriers of CYP21 gene mutations.

K family: Gene conversion-deletion. The affected son lacked a normal CYP21B gene (Fig. 2, subject 14). Whereas a densitometric comparison of CYP21A and CYP21B gene fragments was not performed, a visual comparison of band intensities suggests that the affected son's paternal sixth chromosome had two copies of the CYP21A gene and was missing CYP21B. This was demonstrated by three doses each of the 4.0 kb *Kpn* I fragment and the 3.2 and 2.4 kb *Taq* I fragments and only one dose each of the 2.9 kb *Kpn* I fragment and the 3.7 and 2.5 kb *Taq* I fragments (Fig. 2, subject 12). This hybridization pattern is likely a variant of Morel's gene conversion, congenital adrenal hyperplasia haplotype IV.[14] The affected subject's maternal sixth chromosome had a large deletion of DNA originating in the 2.4 kb *Taq* I fragment downstream from the CYP21A gene, and ending within the 3.7 kb *Taq* I fragment of CYP21B gene (Fig. 2, subject 13). This phenotype is consistent with Morel's congenital adrenal hyperplasia haplotype V, a deletion of approximately 30 kb extending from the middle of the CYP21A pseu-

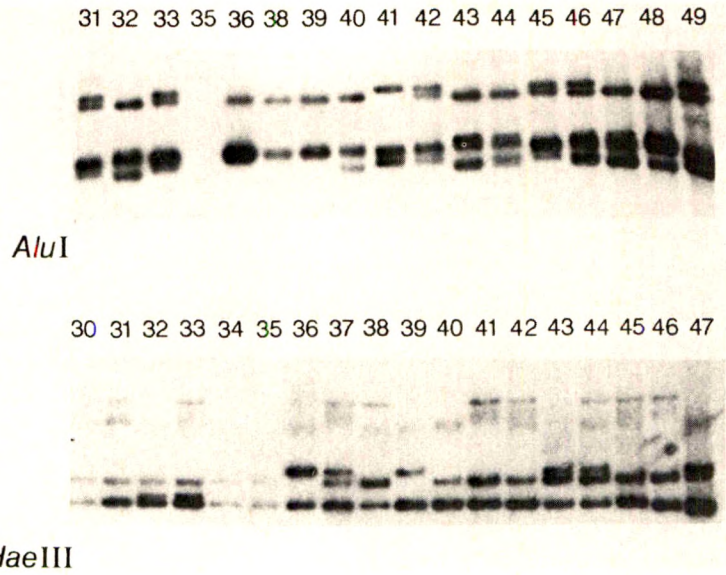

Fig. 3. Denaturing gradient gel electrophoresis blot of *Alu* I and *Hae* III digests of control subjects' genomic DNA. *Alu* I patterns demonstrate melting polymorphism for both upper and lower cluster of fragments. Five distinct fragment melting patterns are represented. *Hae* III patterns demonstrate melting polymorphism, with at least seven different melting patterns present.

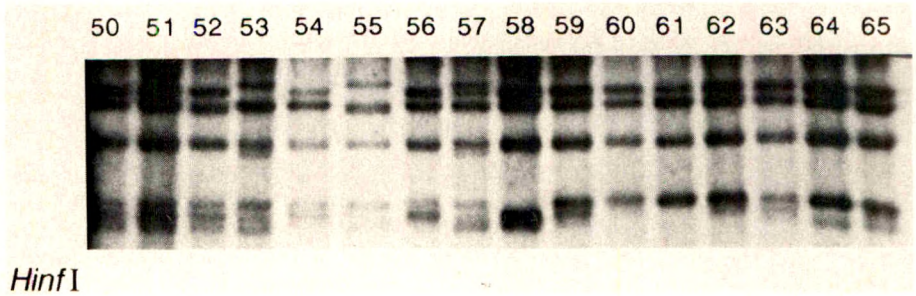

Fig. 4. Denaturing gradient gel electrophoresis blot of *Hin*fI digest of control subjects' genomic DNA. Extensive melting polymorphism is present, with at least seven different *Hin*fI melting patterns represented.

dogene to a corresponding position in the middle of the CYP21B gene. Both of the affected individual's sixth chromosomes were probably inherited intact from the parents, without any recombination or further gene conversion in the CYP21 region (Fig. 2, subject 14).

T family: Homozygous deletion. The affected son was homozygous for a deletion that removes most or all of the CYP21B gene, extending through the C4B gene to the 3′-end of the CYP21A gene. The affected son lacked both the 3.7 and 2.4 kb *Taq* I fragments and also the 2.9 kb *Kpn* I fragment (Fig. 2, subject 15). Genomic DNA from both parents (Fig. 2, subjects 17 and 18), the paternal grandfather (subject 19), and the maternal grandfather (subject 21) demonstrated decreased hybridization intensities for the three fragments absent in the affected son. This deletion corresponds to Morel's congenital adrenal hyperplasia haplotype V as discussed above.[14]

M family: Point mutation or small gene conversion. The affected daughter, unaffected sister (data not shown), and both parents (Fig. 2, subjects 26, 27, and 28) demonstrated normal CYP21 gene *Taq* I and *Kpn* I fragments. This result matches Morel's point mutation congenital adrenal hyperplasia haplotype I.[14] Genomic DNA from the M family was digested with several additional restriction enzymes (*Bgl*I, *Hin*dIII, *Bam*HI, and *Eco*RI), and analyzed on Southern blots. These blots were not different from the blots of normal individuals (data not shown).

Denaturing gradient gel blot analysis

Control subjects. Genomic DNA samples from normal, unrelated volunteers, digested with the restriction enzymes *Alu* I ($n = 84$), *Hae* III ($n = 55$), *Hin*fI ($n = 45$), and *Rsa* I ($N = 40$) were electrophoresed on denaturing gradient gels. Blots prepared from these gels were hybridized with a radioactive probe prepared from CYP21 gene complementary DNA.

In striking contrast to our Southern blot data, most small CYP21 gene fragments from normal, unrelated individuals were polymorphic on denaturing gradient

Fig. 5. Denaturing gradient gel electrophoresis blot of *Alu* I and *Hae* III digests of genomic DNA for congenital adrenal hyperplasia pedigrees and controls. *Controls,* Subjects 10 and 11 are control individuals and demonstrate different fragment melting patterns for each digest. Melting pattern differences are seen in K and T family members and can be followed through each generation represented. *K family (left pedigree),* Affected son is compound heterozygote for gene conversion and gene deletion mutation. Only upper *Alu* I fragment is missing. *T family (middle pedigree),* Affected son is homozygous for CYP21B gene deletion. Both upper fragments in *Alu* I and *Hae* III digests are missing. *M family (right pedigree),* Affected daughter has point mutations. *Alu* I and *Hae* III fragments of her genomic DNA do not differ from those of her parents.

gel blots. Each lane of the blot in Fig. 3 showed polymorphic (two or more gel position phenotypes) *Alu* I fragments. The top fragment in each lane had distinct alleles, with the lower form more common in this group of individuals. The lower cluster of *Alu* I bands was caused by either multiple alleles of a single fragment or a group of several different fragments, with at least one having polymorphic alleles. Taken together, the *Alu* I fragments revealed five distinctive fragment melting patterns. *Hae* III fragments were similarly polymorphic in control individuals (Fig. 3). At least seven different melting patterns were present in the control individuals shown. *Hin*fI digestion of genomic DNA from normal control subjects also revealed extensive polymorphism, as demonstrated by at least seven different melting patterns (Fig. 4). Among three polymorphic *Rsa* I fragments, at least seven different melting patterns were found in normal control DNA (data not shown).

Congenital adrenal hyperplasia family members. Denaturing gradient gel blots of genomic DNA of the K, T, and M congenital adrenal hyperplasia family members were prepared and hybridized with the CYP21 gene complementary DNA probe. *Alu* I and *Hae* III digests electrophoresed on denaturing gradient gels demonstrated an array of melting polymorphisms similar to that found in normal individuals (Fig. 5). The highest *Alu* I fragment was missing in the affected T and K males (Fig. 5, subjects 14 and 15). This result suggests that the missing fragment originated from the CYP21B gene. The presence of this *Alu* I fragment, in either of the two allelic forms, was associated with the absence of congenital adrenal hyperplasia in the T and K families, through four generations.

No restriction fragment melting polymorphisms were found in the *Alu* I and *Hae* III digests of genomic DNA from M family members. The M family was studied further with the restriction enzymes *Hin*fI, *Rsa* I, *Bst*NI, *Sau*3A, *Pst* I, and *Sau*96I. Except for the *Bst*NI digests, the patterns were identical in each set of digests of DNA from the original three M family members, with the addition of an unaffected daughter (Fig. 6). The presence of the lowest *Bst*NI band was associated with congenital adrenal hyperplasia in this small family.

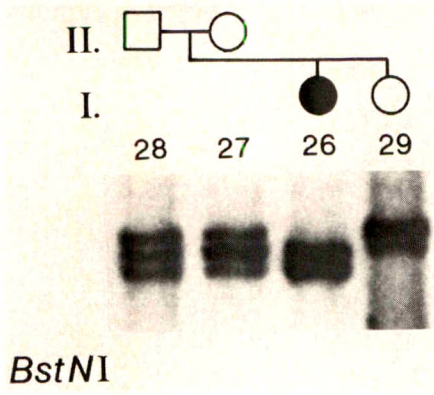

Fig. 6. Denaturing gradient gel electrophoresis blot of *Bst*NI digests of M family genomic DNA. Melting differences are noted between M family members after denaturing gradient gel electrophoresis in *Bst*NI digests only. Restriction fragment melting polymorphism shown here marks CYP21B allele that segregates with congenital adrenal hyperplasia in this family. DNA from the unaffected daughter is included here.

This restriction fragment melting polymorphism marked the CYP21B allele that segregated with congenital adrenal hyperplasia.

Comment

Prior studies that used routine Southern blot analysis demonstrated relatively few easily identifiable polymorphisms within the CYP21 genes. The data presented here with molecular analysis of denaturing gradient gel electrophoresis demonstrate that numerous DNA sequence polymorphisms exist within the CYP21 genes of normal and patients with congenital adrenal hyperplasia. By presenting one family with each of the major types of 21-hydroxylase deficiency mutations, we have demonstrated the mendelian inheritance of these polymorphisms. Furthermore, we have demonstrated the potential clinical usefulness of denaturing gradient gel electrophoresis for the molecular analysis of the CYP21 genes in families affected with 21-hydroxylase deficiency. The rapid identification of single-base differences in the 21-hydroxylase genes will permit a CYP21 gene-specific prenatal diagnosis.

The denaturing gradient gel electrophoresis analysis of the CYP21 genes demonstrated polymorphisms for more than half of the fragments produced by digestion with each of the restriction enzymes tested. These genes appeared to be more highly polymorphic than other autosomal genes studied (Gray MR. Unpublished data). The polymorphisms found within the DNA of control individuals were also present in families carrying each of the three major types of CYP21 gene mutations. Although the T and K families carry CYP21B gene deletion and large gene conversion mutations, our results for the affected T and K individuals suggest that many of the CYP21 gene restriction fragment melting polymorphisms were in the CYP21A pseudogene. CYP21B-specific fragments were also identified: The T male with a gene deletion lacked the highest bands shown in the *Hae* III and *Alu* I blots. The K male retained the highest *Hae* III fragment but lost the highest *Alu* I fragment.

The T and K family denaturing gradient gel electrophoresis results revealed fragments specific for deletion and conversion mutations. Denaturing gradient gel electrophoresis of *Alu* I and *Hae* III digests distinguished between deletion and conversion mutations. Deletion mutations may result in absence of both highest *Alu* I and *Hae* III fragments, and large conversion mutations may result in absence of the *Alu* I fragment only. Further denaturing gradient gel electrophoresis studies of other CYP21 gene deletion and conversion chromosomes are needed to test this finding.

The data on the M family demonstrated that denaturing gradient gel electrophoresis analysis of the 21-hydroxylase genes can be used to identify the affected CYP21 point mutation allele for prenatal diagnosis. Although the *Bst*NI restriction fragment melting polymorphism in the affected female was not likely to be the specific mutation causing congenital adrenal hyperplasia, it was an intragenic marker for the mutation in this family. Denaturing gradient gel electrophoresis can also provide a rapid means of identifying the mutant region of CYP21B and permit a more rapid sequence determination of this specific region.

Recent studies with CYP21A-specific oligonucleotide probes and densitometric analysis of CYP21A and CYP21B-specific gene fragments have provided evidence of frequent genetic interchange between the two 21-hydroxylase genes, even in normal individuals.[11, 20] The extensive number of polymorphisms found by denaturing gradient gel electrophoresis is consistent with observations of extensive genetic activity in the region of the CYP21 genes.

Use of denaturing gradient gel electrophoresis will greatly augment our ability to identify 21-hydroxylase gene mutations. This is important for the 76% of congenital adrenal hyperplasia chromosomes with point mutations not detectable on routine Southern blots.[14] Histocompatibility linkage studies, presently required for prenatal diagnosis of such point mutations, will be enhanced by the adjunctive use of denaturing gradient gel electrophoresis and potentially replaced by this technique. The more direct denaturing gradient gel electrophoresis method permits intragenic diagnosis of congenital adrenal hyperplasia and eliminates the potential misdiagnosis caused by recombination between histocompatibility loci and CYP21B.[5]

In summary, our data provide evidence that the DNA sequences of the 21-hydroxylase genes are highly polymorphic in all individuals. Our data demonstrate the

potential clinical usefulness of denaturing gradient gel electrophoresis for the intragenic prenatal diagnosis of 21-hydroxylase deficiency.

We thank Dr. Perrin White for providing the CYP21 gene probes.

Transforming growth factor-α and epidermal growth factor messenger ribonucleic acid and protein levels in human placentas from early, mid, and late gestation

Francois Bissonnette, MD,[a] Christine Cook, MD,[a] Thomas Geoghegan, PhD,[b] Marlen Steffen, BS,[b] John Henry, PhD,[b] Marvin A. Yussman, MD,[a] and Gregory Schultz, PhD[c]

Louisville, Kentucky, and Gainesville, Florida

OBJECTIVE: Human placenta expresses receptors for transforming growth factor-α and epidermal growth factor throughout pregnancy. Experiments were performed to determine whether epidermal growth factor or transforming growth factor-α might be synthesized by placental cells and act through an autocrine mechanism to influence functioning of placental cells in vivo.

STUDY DESIGN: Human placentas from early, mid, and late gestations were analyzed for transforming growth factor-α and epidermal growth factor messenger ribonucleic acid and proteins. Polyadenylic acid–positive ribonucleic acid was isolated from placentas from 10, 11, 13, 21, 32, 38, 39, and 40 weeks of gestation and analyzed by Northern analysis for hybridization with complementary deoxyribonucleic acid probes specific for epidermal growth factor or transforming growth factor-α. Levels of immunoreactive epidermal growth factor and transforming growth factor-α were measured by specific radioimmunoassays in pools of placentas from early, mid, and late gestations, and levels of epidermal growth factor and transforming growth factor-α receptor–active protein were measured by radioreceptor assay.

RESULTS: All placentas had a strong transforming growth factor-α hybridization band at 4.5 kb and a weak epidermal growth factor hybridization band at 5.2 kb. High levels of transforming growth factor-α immunoreactive protein (90 to 180 ng/mg protein) and low levels of immunoreactive epidermal growth factor (3 to 9 pg/mg protein) were detected in pools of placentas from early, mid, and late gestations. High levels of epidermal growth factor and transforming growth factor-α receptor–active protein (250 ng/mg protein) were also detected.

CONCLUSION: Human placentas contain relatively high levels of immunoreactive and receptor–active transforming growth factor-α, as well as transforming growth factor-α messenger ribonucleic acid, throughout gestation. This finding suggests that transforming growth factor-α may act by an autocrine system to influence human placental cell function in vivo. (Am J Obstet Gynecol 1992;166:192-9.)

Key words: Growth factors, transforming growth factor-α, epidermal growth factor, placenta, messenger ribonucleic acid, autocrine systems

Transforming growth factor-α (TGF-α) and epidermal growth factor (EGF) are structurally related polypeptides that bind to a common cellular receptor protein, the EGF–TGF-α receptor.[1, 2] They are potent mitogens for many types of cells, including epithelial cells and fibroblasts. In addition to their mitogenic action, EGF and TGF-α can influence specialized functions of several types of differentiated cells. EGF rapidly stimulated prolactin synthesis and inhibited growth hormone synthesis in rat pituitary cell cultures[3] and inhibited gastric acid secretion by guinea pig parietal cells.[4]

Several lines of evidence suggest that TGF-α or EGF may play important physiologic roles in fetal-placental development and function. Human placental membranes express high levels of EGF–TGF-α receptors throughout gestation.[5-7] Although the physiologic actions of EGF or TGF-α on human placental cells are not completely understood, they may influence synthesis of placental hormones. EGF stimulated secretion of chorionic gonadotropin and prolactin by normal hu-

man placental trophoblasts in short-term culture.[8-10] In addition, EGF stimulated synthesis of progesterone by JEG-3 human choriocarcinoma cells in culture[11] and attenuated follicle-stimulating hormone–induced estrogen synthesis by rat granulosa cells.[12] The effects of TGF-α on placental cell functions have not been examined.

The source(s) of TGF-α or EGF that could influence human placental function in vivo has not been determined. EGF or TGF-α could be produced by maternal cells and delivered to the placenta through the maternal circulation by a typical endocrine mechanism. The growth factors also could be synthesized by fetal syncytiotrophoblast cells or produced by maternal decidua cells and act by autocrine or paracrine mechanisms to influence fetal syncytiotrophoblasts.

Initial reports of blood levels of EGF indicated that plasma levels of immunoreactive EGF material in nonpregnant women were very low (30 pmol/L) and did not increase during pregnancy.[13] Subsequent studies demonstrated that immunoreactive EGF material detected in platelet-rich plasma and serum was generated from degranulated platelets, which suggested that plasma does not normally contain physiologically significant levels of EGF.[14, 15] Plasma levels of immunoreactive TGF-α from normal individuals were recently reported to be approximately 5 pmol/L, which is below the level of TGF-α that significantly stimulates mitosis of most cells in vitro.[16] Plasma levels of TGF-α have not been reported for pregnant women. Thus it seems unlikely that placental cells would be influenced significantly by either EGF or TGF-α in maternal blood.

Results of experiments in mice and rats suggest that TGF-α or EGF may influence rodent placental cells by autocrine or paracrine mechanisms. Before development of the placenta, TGF-α messenger ribonucleic acid (mRNA) and protein (but not EGF, basic fibroblast growth factor, nerve growth factor, granulocyte colony-stimulating factor) were detected in mouse preimplantation blastocysts.[17] After implantation of rat embryos, high levels of TGF-α mRNA were detected in rat maternal decidua; then mRNA levels slowly declined as the decidua was resorbed.[18] At day 14 of gestation, low levels of TGF-α mRNA were also detected in rat placental tissue. Human placenta has not been analyzed for TGF-α and EGF mRNA and proteins.

To help assess if EGF or TGF-α might interact with human placental cells by autocrine or paracrine mechanisms, we used complementary deoxyribonucleic acid (cDNA) hybridization techniques and specific radioimmunoassays (RIA) and radioreceptor assays to analyze samples of normal human placental tissues obtained during early, mid, and late gestation for the presence of TGF-α and EGF mRNA and proteins.

Material and methods

Placental tissue collection. Early human placental material was obtained from curettage of the uterus during the first trimester of pregnancy. Placentas from mid and late gestation were obtained at delivery. Care was taken to select only fetal placental tissue. Placental tissues were immediately washed with saline solution, frozen in liquid nitrogen, and then stored at −70° C. The gestational age was determined from the date of the last menstrual period or from clinical or ultrasonographic evaluation. Tissues were procured under appropriate guidelines of the Human Study Committee and the Animal Care and Use Committee of the University of Louisville and the University of Florida.

Preparation of ribonucleic acid (RNA). Total RNA was prepared from frozen tissues by slight modifications of the method of Rall et al.[19] Briefly, tissues were homogenized in 10 volumes of 5 mol/L guanidinium thiocyanate containing 100 mmol/L Tris hydrochloride, pH 7.6, 10 mmol/L ethylenediaminetetraacetic acid (EDTA), and 14% 2-mercaptoethanol. Homogenates were centrifuged at 10,000*g* for 10 minutes at 4° C and RNA precipitated from the supernatants by overnight incubation at 4° C in 5.5 volumes of 4 mol/L lithium chloride. Pellets were resuspended and washed with a solution of 3 mol/L lithium chloride containing 4 mol/L urea until the supernatant was clear. Samples were dissolved in 10 mmol/L Tris hydrochloride, pH 8.0, and 0.5% sodium dodecyl sulfate and then digested with protease K (200 μg/ml) for 30 minutes at 30° C. RNA was further deproteinized by extraction with phenol/chloroform/isoamyl alcohol (1:1:0.1) and recovered by overnight precipitation with 66% ethanol and 33% 0.1 mol/L sodium chloride. RNA samples were stored at −20° C in ethanol–sodium chloride.

Polyadenylic acid–positive RNA was isolated from total RNA by oligo(dT)-cellulose chromatography.[20] Samples of total RNA were dissolved in 500 mmol/L sodium chloride, 10 mmol/L Tris hydrochloride, pH 7.6, 1 mmol/L EDTA, and 0.5% sodium dodecyl sulfate (binding buffer) and mixed for 30 minutes with the oligo(dT)-cellulose resin (previously equilibrated with binding buffer). Suspensions of resin were then poured into columns and washed successively with binding buffer, intermediate buffer (100 mmol/L sodium chloride, 10 mmol/L Tris hydrochloride, pH 7.6, 1 mmol/L EDTA, 0.5% sodium dodecyl sulfate), and elution buffer (10 mmol/L Tris hydrochloride, pH 7.6, 1 mmol/L EDTA, 0.5% sodium dodecyl sulfate. Polyadenylic acid–positive RNA was recovered by precipitation of the elution buffer with ethanol–sodium chloride. RNA concentrations were determined by absorbance at 260 nm (one A_{260} unit equaling 40 μg/ml RNA).

Hybridization analysis. Northern blots were performed as described with slight modifications.[20] Briefly, samples of polyadenylic acid–positive RNA (5 μg) were denatured by heating at 55° C for 15 minutes in a solution containing 50% formamide, 2.2 mol/L formaldehyde, 20 mmol/L MOPS buffer (3-{N-morpholino}propanesulfonic acid), pH 7.0, 5 mmol/L sodium acetate, and 0.5 mmol/L EDTA. Samples were subjected to electrophoresis at 35 V for 20 hours through a 1% agarose gel containing 2.2 mol/L formaldehyde, 40 mmol/L MOPS, pH 7.0, 10 mmol/L sodium acetate, and 1 mmol/L EDTA. Total placental RNA was also subjected to electrophoresis and analyzed by ethidium bromide staining to determine location of 18S and 28S ribosomal size markers. RNA was blotted onto nylon filters by capillary transfer and fixed by heating at 80° C. Blots were prehybridized at 42° C for 2 hours in a solution containing 50% formamide, 5× SSPE (1× SSPE is 0.18 mol/L sodium chloride, 10 mmol/L sodium phosphate, pH 7.7, and 1 mmol/L EDTA), 5× Denhardt's solution (50× Denhardt's is 1% acetylated bovine serum albumin, 1% ficoll, and 1% polyvinylpyrrolidone), 0.1% sodium dodecyl sulfate, and denatured salmon sperm deoxyribonucleic acid (DNA) (200 μg/ml). Hybridization was performed for 16 hours at 42° C in the same solution but containing 10% dextran sulfate and 10^6 counts/min/ml of phosphorus 32–labeled TGF-α or EGF probe. After hybridization, blots were washed four times with 2× SSPE containing 0.1% sodium dodecyl sulfate for 5 minutes each and twice with 0.2× SSPE and 0.1% sodium dodecyl sulfate at 65° C for 15 minutes each. Autoradiograms were generated by exposing the blots to Kodak AR (Eastman Kodak, Rochester, N.Y.) film with DuPont (DuPont Instruments, Wilmington, Del.) intensifying screen for 24 hours at −80° C.

TGF-α and EGF cDNA probes. The rat TGF-α cDNA probe was kindly provided by Oncogen (Seattle) and consisted of a 2.3 kb *Eco*RI insert subcloned into pEBBL.[21] The TGF-α cDNA clone encodes the entire 159 amino acid precursor TGF-α molecule and has been shown to hybridize to a single species of approximately 4.5 kb with rat RNA. The gene for human TGF-α also has been cloned and was found to encode for a 160 amino acid precursor polypeptide.[22] Hybridization of a human TGF-α cDNA probe to polyadenylic acid–positive RNA obtained from normal human skin also generated a single band of approximately 4.5 to 4.8 kb.[23]

The human EGF cDNA probe was kindly supplied by Chiron Corporation (Emeryville, Calif.). It encodes the entire 1207 amino acid precursor form of EGF and consisted of a 6.4 kb *Sma* I insert cloned into pSAD.[24] The probe has been shown to hybridize to a single transcript of 5.0 to 5.2 kb from adult human kidney polyadenylic acid–positive RNA.[24] Both the TGF-α and EGF cDNA probes were radiolabeled to a specific activity of approximately 10^9 counts/min/μg with an oligonucleotide random priming kit (Amersham Corp., Arlington Heights, Ill.).

RIAs for EGF and TGF-α. Individual placentas from fetuses at early and mid gestation were too small to permit RIAs for both EGF and TGF-α. Thus samples of placental tissue were formed by combining individual placentas of early, mid, and late gestation. Each pooled sample contained 5 gm of tissue. The sample from early gestation contained tissue from nine placentas of 9 to 13 weeks' gestation. The samples from mid and late gestation each contained tissue from six placentas of 21 to 32 weeks' gestation and 33 to 40 weeks' gestation, respectively.

TGF-α immunoreactive protein was measured with an RIA kit specific for TGF-α, obtained from BioTope (Seattle). Placental samples were extracted with denaturing detergent and reduced according to manufacturer's instructions, and samples were assayed in triplicate at three dilutions. Displacement data were linearized by logit transformation, and the best fit line was determined by linear regression analysis. Slopes of the lines generated by placental samples and by the TGF-α standard were compared for differences by *t* test for slopes.[25] Samples that produced displacement lines that were parallel to TGF-α standard were considered to contain immunoreactive TGF-α. Levels of immunoreactive TGF-α protein were expressed as nanograms of immunoreactive TGF-α per milligram of protein determined by BCA protein assay (Pierce Chemical Co., Rockford, Ill.). The half-maximal displacement occurred at approximately 20 nmol/L TGF-α, and nonspecific binding was approximately 3% of total binding. All samples were analyzed in a single assay, and the intraassay coefficient of variation was 3%. The TGF-α RIA used polyclonal goat antiserum generated to the C-terminal 17 amino acid sequence of TGF-α (amino acids 34 to 50). The RIA is highly specific for TGF-α (no cross-reactivity with mouse or human EGF at 1 μmol/L).

EGF immunoreactive protein was measured with minor modifications to a solid-phase RIA described previous.[26] Briefly, placental samples were extracted with 1% Triton X-100 detergent in phosphate-buffered saline (PBS) solution and assayed in triplicate at three dilutions. Displacement data were linearized by logit transformation, and slopes of lines determined by linear regression analysis were analyzed for differences with *t* test for slopes as described. Levels of immunoreactive EGF protein were expressed as nanograms of immunoreactive EGF per milligram of protein determined by BCA protein assay. Half-maximal displacement for the assay was approximately 300 pmol/L, and nonspecific binding was <15%. All placental samples

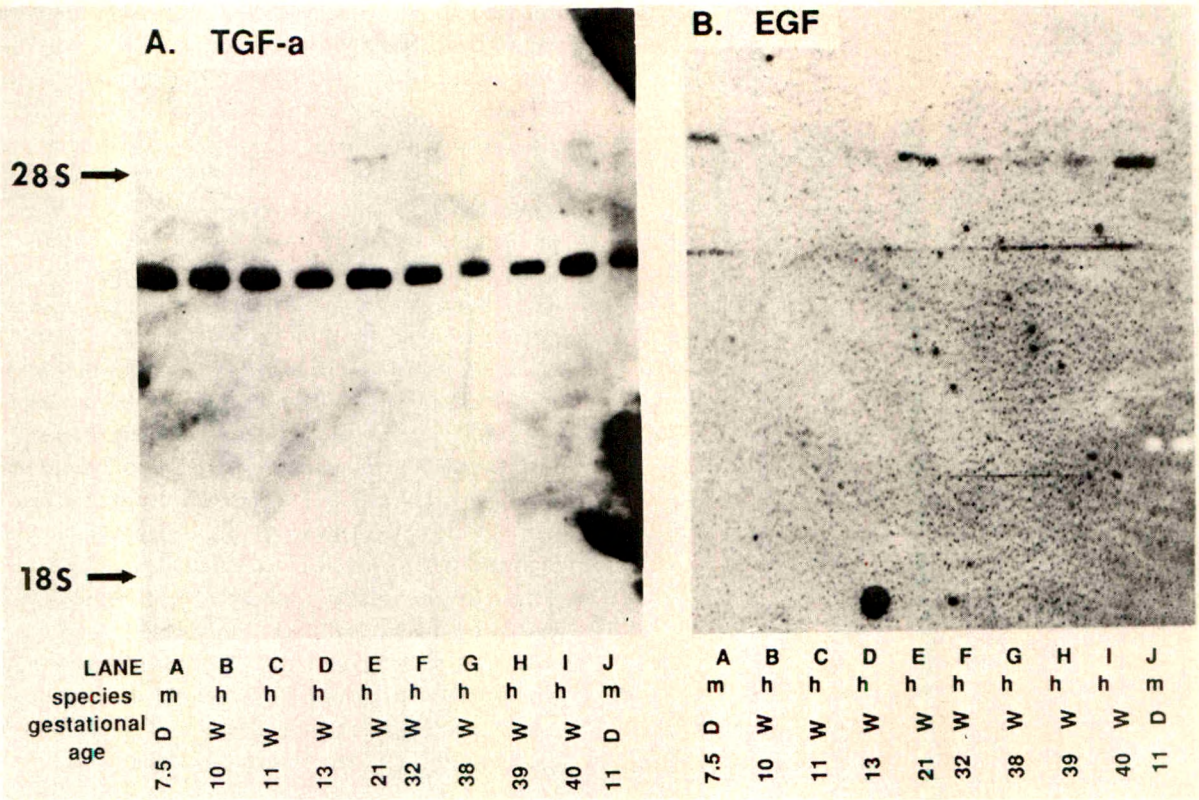

Fig. 1. Northern analysis of placental polyadenylic acid–positive RNA for TGF-α and EGF mRNA. Polyadenylic acid–RNA (5 μg per lane) was isolated from mouse *(lanes A and J)* or human *(lanes B through I)* placentas of varying gestational ages (*lane A*, 7.5 days; *lane J*, 11 days; *lanes B through I*, 10, 11, 13, 21, 32, 38, 39, and 40 weeks, respectively). Blots were hybridized under high-stringency conditions with cloned cDNA for rat TGF-α **(A)** and human EGF **(B).** TGF-α probe in **A** hybridized to 4.5 kb mRNA and EGF probe hybridized to 5.2 kb mRNA.

were analyzed in a single assay, and the intraassay coefficient of variation was approximately 10%. The EGF RIA used polyclonal rabbit antiserum generated to the complete 53 amino acid sequence of recombinant human EGF. The RIA is highly specific for EGF (no cross reactivity with human TGF-α at 1 μmol/L).

Radioreceptor assay for TGF-α and EGF. Placentas from five fetuses of early gestation (6 to 9 weeks) and five of late gestation (37 to 42 weeks) were individually homogenized at 4° C in 5 ml PBS solution with a Polytron (Brinkmann Instruments, Westbury, N.Y.) homogenizer. Samples were centrifuged at 30,000*g* for 30 minutes at 4° C, and the supernatants were assayed for EGF receptor-active material with a modification of a radioreceptor assay described previously.[27] Briefly, confluent cultures of FaDu human squamous carcinoma cells (American Type Culture Collection, Bethesda, Md.) were washed with PBS solution and then fixed by brief exposure to 10% neutral buffered formalin for 10 minutes at room temperature. The fixed cells were washed with PBS solution containing 130 mmol/L glycine, pH 7.5, for 30 minutes to quench residual formalin, and then 100 μl of placental supernatant or standard EGF solution was added to wells along with 100 μl of iodine 125–EGF. After 2 hours of incubation at 37° C, the cells were washed three times with PBS solution and dissolved in 1 ml 4N sodium hydroxide, and the radioactivity was measured by γ-counter. Placental samples were assayed in duplicate at three dilutions and the displacement data were linearized by logit transformation. Slopes of lines generated by placental samples and EGF standard were compared for differences by *t* test for slopes. Levels of EGF receptor–active material were expressed as picograms EGF–TGF-α per milligram protein as determined by BCA protein assay.

Results

Northern blot analysis. Northern blot hybridization of polyadenylic acid–positive RNA from individual placentas obtained at various stages of gestation are shown in Fig. 1, *A*. Hybridization with the TGF-α cDNA probe generated a major band corresponding to a 4.5 kb mRNA for all the human placenta samples (lanes B through I). In addition, a similar size species was detected in polyadenylic acid–positive RNA from mouse

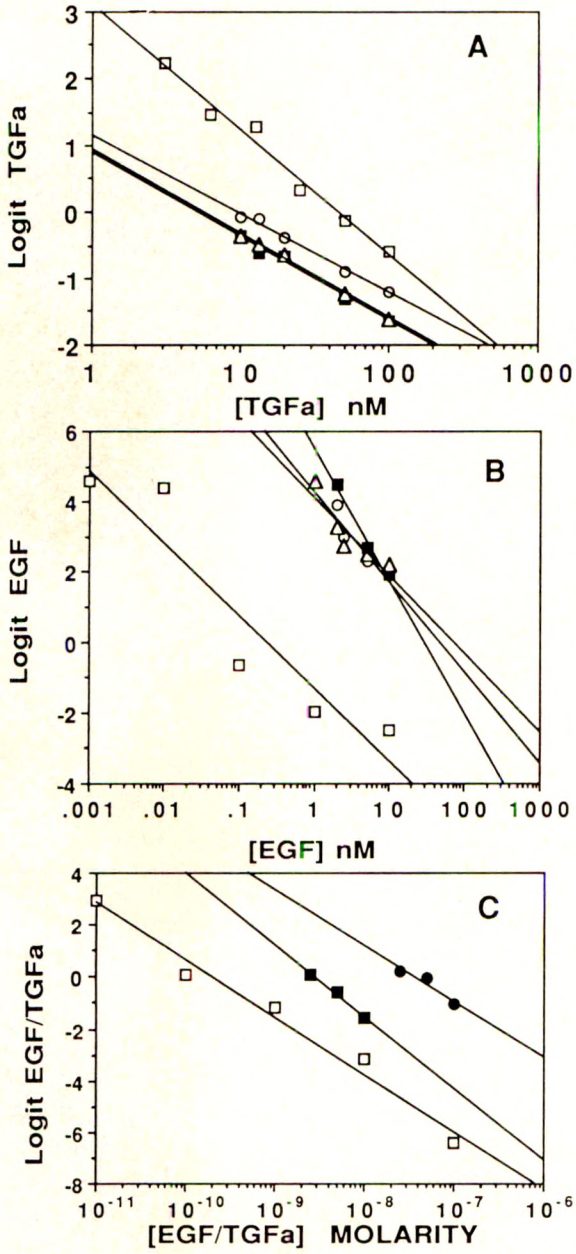

Fig. 2. Analysis of placental extracts for TGF-α and EGF immunoreactive proteins and for biologically active EGF and TGF-α proteins. Pools of human placentas from early, mid, and late gestation were extracted and analyzed for immunoreactive TGF-α **(A)** or EGF **(B)** with specific radioimmunoassays. Symbols for samples: EGF (□) or TGF-α (□) standards; early gestation (○); mid gestation (■); and late gestation (△). Analysis of placental homogenates for biologically active EGF or TGF-α proteins is shown in **C.** Homogenates of two placentas at 37 (●) and 42 (■) weeks produced displacement lines that were parallel to that generated by standard EGF (□).

decidual-placental tissue obtained at 7.5 and 11 days' gestation (lanes A and J). The size of the major hybridization band (4.5 kb) agrees with previous reports for rat TGF-α mRNA[18, 21] and human TGF-α mRNA.[23]

In addition to the major 4.5 kb species, a faint hybridization band was detected at approximately 5.4 kb in samples of 21-, 32-, and 40-week human placentas and in both mouse placenta samples. The 5.4 kb band may result from weak cross-hybridization of the TGF-α cDNA probe to EGF mRNA, which migrates at approximately the same position.

Hybridization of the same samples of polyadenylic acid–positive RNA with the EGF cDNA probe generated a faint band at 5.2 kb in all the human placentas and in both samples of mouse placenta (Fig. 1, *B*). The size of the hybridization band agreed with the size reported for prepro-EGF mRNA isolated from mouse submaxillary gland of 5.0 to 5.3 kb.[28] The intensity of the EGF cDNA hybridization signal was substantially less than that of the TGF-α cDNA hybridization signal, although the specific activity of the cDNA probes and exposure times were approximately equal.

Northern hybridization was also performed on samples of total RNA isolated from pooled placentas of early, mid, and late gestation. No hybridization bands were detected with either the TGF-α or the EGF probe, even when 10 μg of total RNA of each sample was applied to the gel (data not shown). The failure to detect hybridization bands with samples of total RNA suggests that, under the high-stringency conditions used, the TGF-α and EGF probes did not hybridize nonspecifically to RNA species present in total RNA samples and, additionally, that the levels of mRNA for TGF-α and EGF were too low to be detected by Northern analysis of total RNA samples.

RIAs for TGF-α and EGF. Detection of mRNA for TGF-α and EGF in individual placentas indicated that placental cells had the potential to synthesize TGF-α and EGF proteins. To further investigate whether the mRNA might be translated into protein, samples of placentas from early, mid, and late gestation were extracted and analyzed for TGF-α and EGF protein by specific RIAs. As shown in Fig. 2, *A*, samples of placentas from early, mid, and late gestation each generated linear displacement curves that were parallel to the TGF-α standard curve, indicating the presence of immunoreactive TGF-α protein in the samples. As shown in Table I, the levels of immunoreactive TGF-α protein measured in samples of placentas from mid or late gestation (approximately 90 ng/mg protein) were about one half the level measured in the pool of placentas from early gestation (188 ng/mg protein).

In comparison with other tissues, placenta appears to be a very rich source of TGF-α. Levels of immunoreactive TGF-α protein measured in samples of placentas from mid or late gestation were approximately fivefold higher than those measured in acid-ethanol extracts of normal and psoriatic epidermis (approxi-

mately 17 ng/mg protein),[29] approximately twentyfold higher than levels measured in chemically induced rat mammary tumors (approximately 0.5 ng/mg),[30] and approximately thirtyfold higher than levels measured in human breast cancer cell lines (3 ng/mg).[31] However, the levels of TGF-α immunoreactive protein measured in placenta or other tissues by RIA may not represent the levels of biologically active TGF-α present in the samples, because the RIA for TGF-α only detects antigenic structures present in the C-terminal 17-mer of TGF-α, which has been shown to lack the complete receptor-binding domain of intact TGF-α.[32]

Analysis of the early, mid, and late placental samples with the EGF RIA also produced linear displacement curves that were parallel to the EGF standard curve (Fig. 2, *B*). As shown in Table I, levels of immunoreactive EGF measured in the three samples from different gestational periods (between 3 and 9 pg/ml) were approximately 10,000-fold lower than the levels of TGF-α immunoreactive material. Levels of immunoreactive EGF protein have been reported for a number of other human tissues and fluids; however, these levels were usually expressed on the basis of the wet weight of tissues or the volume of fluid samples rather than on the basis of milligrams of protein in the sample. For example, the average concentration of immunoreactive EGF in cerebrospinal fluid was 233 pg/ml for men and 206 pg/ml for women.[33] Urinary levels of EGF at birth averaged 12 pg/ml (38 ng/ml creatinine), which increased during the first 2 years to approximately 70 mg/ml (170 ng/mg creatinine), then gradually decreased until puberty to approximately 82 ng/ml (70 ng/ml creatine).[34] EGF immunoreactivity has also been reported in saliva (1.9 ng/ml),[35] in seminal plasma (53 ng/ml),[36] and in milk (5 ng/ml).[37] Levels of immunoreactive EGF in homogenates of human tissues were highest in kidney (5.5 ng/gm tissue) and thyroid gland (5.3 ng/gm tissue).[38] Very high levels of EGF were found in mouse submaxillary glands (580 ng/mg protein, approximately 100,000 times higher than in human placenta), indicating that the submaxillary gland is a major site of EGF synthesis in mice.[39]

Radioreceptor assay for EGF–TGF-α. Levels of biologically active EGF and TGF-α proteins in placentas from early and late gestation were determined by radioreceptor analysis of placental homogenates. As shown in Fig. 2, *C*, supernatants of representative placental homogenates generated displacement curves that were parallel to the EGF standard curve, indicating the presence of EGF and TGF-α receptor–active protein in the samples. The average concentrations of EGF and TGF-α receptor–active protein were similar in placentas from early (246 ± 157 ng/mg protein) and late (249 ± 97 ng/mg protein) gestation. These levels of EGF and TGF-α receptor–active protein were slightly higher than the average level of immunoreactive TGF-α protein (124 ng/mg protein) measured in placentas from early, mid, and late gestation.

Table I. Levels of immunoreactive TGF-α and EGF protein in pools of human placentas from early, mid, and late gestation

Stage of gestation	*TGF-α (ng/mg)*	*EGF (pg/mg)*
Early	189 ± 28	8 ± 3
Mid	93 ± 13	3 ± 1
Late	91 ± 12	9 ± 2

Placentas from different stages of gestation were pooled, extracted, and analyzed for EGF or TGF-α proteins with specific RIAs. All placental samples generated displacement curves with slopes parallel to EGF or TGF-α standard curves. Values are mean ± SE of concentrations determined from logit transformation of multiple dilutions of samples and are expressed as nanogram equivalents of EGF or TGF-α per milligram of soluble protein.

Comment

Previous reports have implicated TGF-α, EGF, and their receptors in the development and functioning of the placenta in vivo. These include the expression of the TGF-α–EGF receptor by placental cells[5-7] and EGF stimulation of secretion of placental peptide and steroid hormones by cultures of placental cells in vitro.[8-11] However, the source of TGF-α or EGF that could influence placental cell function has not been established. Circulating plasma levels of EGF and TGF-α appear to be too low to significantly influence placental cells[13-16]; therefore production of the factors by placental cells is a more likely source.

Our results demonstrate the presence of substantial levels of TGF-α mRNA and high levels of immunoreactive and receptor-active TGF-α protein in extracts of human placental tissue throughout gestation. These results support the concept that TGF-α may act by an autocrine or paracrine mechanism to influence human placental cells. Additional studies are needed, however, to determine if the TGF-α and EGF mRNA is translated into protein and which cells in the maternal-fetal-placental unit synthesize the proteins before it can be conclusively determined that these peptides influence placental cells by autocrine or paracrine mechanisms.

Although human placenta has not been analyzed previously for TGF-α mRNA and immunoreactive protein throughout gestation, human term placenta was reported to contain biologic activity consistent with either EGF or TGF-α. Stromberg et al.[40] reported that acid-ethanol extracts of term human placentas contained four different size species (6, 10, 20, and 30 kd) that stimulated growth of NRK cells in soft agar and competed for binding of ^{125}I-EGF to EGF–TGF-α membrane receptors. Levels of EGF and TGF-α receptor–

binding activity were in the range of 11 ng of EGF equivalents per placenta. Interestingly, analysis of the 6 and 10 kd samples for EGF by a specific human RIA failed to detect any immunoreactive EGF material. Thus their results generally agreed with our finding of low levels of immunoreactive EGF protein.

In a study of mouse embryos, Nexo et al.[41] detected low levels of immunoreactive EGF in extracts of 15-day embryos (approximately 1 ng/gm wet weight) that were approximately fortyfold lower than the levels of EGF and TGF-α receptor–active material detected in 12- to 17-day mouse embryos. Popliker et al.,[42] however, reported no detectable levels of EGF mRNA in mouse fetuses or placenta from day 9 of gestation through birth. They reported that the onset of endogenous synthesis of EGF began in neonatal mice in the kidney at 2 weeks post partum. These results lead them to conclude that immunoreactive EGF protein and EGF receptor–active protein detected in mouse fetus and placenta were probably of maternal origin. Taken together, these series of studies[40-42] suggest that placental tissue from mouse, rat, and human contains little or no immunoreactive EGF protein but does contain substantial levels of EGF and TGF-α receptor–active protein(s). On the basis of our analysis of human placentas for EGF and TGF-α mRNA, immunoreactive proteins, and receptor–active proteins, the paradoxic results reported previously of low levels of immunoreactive EGF protein but high levels of EGF and TGF-α receptor–active proteins may be due to placental synthesis of TGF-α protein that was not detected by EGF RIAs but was detected by EGF–TGF-α radioreceptor assays.

Our results do not establish which cells within the human placenta synthesize TGF-α mRNA or which cells contain TGF-α protein. In situ hybridization studies with cDNA probes specific for TGF-α could indicate which placental cells contain TGF-α mRNA, and immunohistochemical analysis with antibodies specific for TGF-α could designate which cells contain immunoreactive TGF-α. Han et al.[18] used in situ hybridization and Northern blot analysis to demonstrate that maternal decidual cells of 8-day rat fetuses were the primary source of TGF-α mRNA, not embryo cells. At 14 days of gestation, however, they detected low levels of TGF-α mRNA in rat placental cells. Human uterine decidual cells have not been examined for TGF-α mRNA or protein, and particular care was taken to exclude any maternal decidual cells or uterine cells in the samples of human placentas. If human decidual cells synthesize and secrete TGF-α or EGF, it is possible that the peptides could influence placental syncytiotrophoblasts through a paracrine mechanism.

The substantial levels of TGF-α mRNA and protein detected in human placenta throughout gestation provide evidence that supports the concept that TGF-α and its receptor may influence normal human fetal placental development and function. Additional studies are needed, however, to begin to understand what roles TGF-α and its receptor play in normal and abnormal human placental function. Insight might be gained by determining if levels of TGF-α mRNA and protein are altered significantly during abnormal placental development. In this initial study of normal placentas, Northern analysis of polyadenylic acid–positive RNA from eight individual human placentas suggested that TGF-α mRNA levels were similar throughout gestation and immunoreactive TGF-α protein levels were similar in pools of placentas from early, mid, and late gestation. Further studies will be required to accurately assess whether TGF-α mRNA and protein levels change significantly during normal and abnormal placental development, but the apparent autocrine action of TGF-α in human placenta suggests that TGF-α and its receptor may play key roles in placental physiologic characteristics.

Oxytocin given in a pulsatile manner to the ewe at 120 to 140 days' gestational age increases fetal sheep plasma cortisol

Drew W. Sadowsky, BA, Juliann Martel, MS, Theresa Cabalum, MD, M. Gabriella Poore, DVM, PhD, and Peter W. Nathanielsz, MD, PhD

Ithaca, New York

A single intravenous injection of oxytocin into pregnant sheep (123 to 144 days' gestational age) causes a bout of myometrial activity and an increase in fetal plasma corticotropin levels. We hypothesized that a sustained increased frequency of myometrial contractures accelerates the normal increase in fetal adrenal secretion in sheep in the last 3 weeks of gestation. To test this hypothesis, pulses of saline solution (group 1, 9 ewes and 10 fetuses) or oxytocin (group 2, 11 ewes and 12 fetuses) 600 or 960 μU/kg/min for 5 of every 30 minutes were infused into the maternal jugular vein for 6 days beginning at day 128 ± 2 (mean ± SD) days' gestational age. Total myometrial activity increased to 160% of baseline in group 2 by day 6. Myometrial activity did not change throughout the study in group 1. Maternal plasma cortisol concentrations did not rise during oxytocin infusion when compared with their own baselines (group 2) and were not different from concentrations in saline-infused ewes (group 1). By day 4 of oxytocin administration fetal plasma cortisol concentrations had risen significantly above baseline in group 2 ($p < 0.05$). Fetal plasma cortisol concentrations did not rise in group 1. Corticotropin levels were not elevated in the fetal carotid arterial plasma of either group. A small but significant decrease occurred in fetal carotid arterial Po_2 in group 2 by day 6 but not in group 1. In conclusion, increased myometrial activity produced by pulsed oxytocin is accompanied by increased fetal plasma cortisol concentrations, demonstrating that long-term alteration of myometrial activity affects fetal adrenal function over several days at this critical period of gestation. (Am J Obstet Gynecol 1992;166:200-5.)

Key words: Pulsatile infusion, oxytocin, fetal cortisol, myometrial contractility, fetal sheep

Spontaneous myometrial activity occurs throughout the second half of pregnancy in many species, including sheep,[1] rhesus monkey,[2] and human beings.[3] Epochs of myometrial activity of prolonged duration (3 to 15 minutes) are called contractures and are the predominant form of activity until the onset of labor, when they are replaced by short-lived, expulsive contractions. Contractures are time-associated with various physical stimuli to the fetus: decrease in fetal arterial Po_2[4]; deformation of the fetus, as seen as a decrease in the dorsal-ventral and an increase in the transverse dimensions of the chest wall diameter[1]; increase in intracranial pressure[5]; and a redistribution of fetal blood to the carcass away from the placenta.[6] Oxytocin-induced contractures have been shown to stimulate fetal corticotropin secretion.[7] At 123 to 144 days' gestational age a 100 mU oxytocin bolus given to a pregnant ewe caused a single myometrial electromyographic epoch of activity and an elevation in fetal corticotropin levels to 145% of baseline. Corticotropin levels remained elevated for 20 minutes.[7]

Ovine fetal plasma cortisol begins to rise slowly from 10 to 40 pg/ml over the last 20 days of pregnancy.[8] Maturation of the fetal hypothalamic-pituitary-adrenocortical axis plays an important role in the initiation of parturition as well as in the maturation of many fetal organ systems. We hypothesize that a sustained increase in the frequency of myometrial contractures in the last 3 weeks of gestation will alter fetal adrenocortical function in the sheep. We elected to increase myometrial activity with a regimen of 5-minute pulses of oxytocin administered intravascularly to the ewe every 30 minutes because this regimen is effective in increasing contracture frequency for several days without the loss in efficacy in stimulating myometrial activity that occurs when oxytocin is continuously infused.[9]

Material and methods

Care of animals. Twenty Rambouillet and Dorset cross ewes of known gestational age were used in these studies. Two ewes, one from each group, had twin fetuses. Animals were housed in metabolic cages and given free access to alfalfa cubes and water ad libitum. Lights were on for 16 hours each day beginning at

6 AM. New York State College of Veterinary Medicine guidelines for the care and use of the sheep were followed. Experiments were conducted under an approved Cornell Institutional Animal Care and Use Committee protocol.

Before surgery animals were divided into two groups: group 1 (saline solution control; 9 ewes, 10 fetuses) and group 2 (oxytocin-infused; 11 ewes, 12 fetuses). Surgery was conducted with halothane general anesthesia at 118 ± 2 days' gestational age (mean ± SD) with techniques described previously.[1] Ewes were instrumented with polyvinyl catheters placed in the jugular vein and carotid artery and with multistrand bipolar stainless steel wires (AS632; Cooner Sales Co., Inc., Chatworth, Calif.) sewn 5 mm apart into the myometrium of the pregnant horn to record a myometrial electromyogram. Each fetus was instrumented with polyvinyl catheters inserted into the jugular vein and carotid artery, stainless steel wires terminating in metal pins inserted bilaterally through the frontal bone into the dura to record the fetal electroencephalogram, and electrode wires sewn into the fascia above and below both eyes to record the fetal electrooculogram and sewn into the deep nuchal antigravity muscles of the neck.[1] Fetal electrophysiologic data are not reported here.

Oxytocin infusion. Both groups of sheep were allowed a 7-day period for recovery from surgery and a further 2-day period for collection of baseline myometrial electromyography and plasma samples for hormone measurement. The experimental period began immediately after the baseline period. In group 2, pulses of oxytocin (Anthony Products, Arcadia, Calif.) were infused into the maternal jugular vein beginning at 128 ± 2 days' gestational age (day 1) at a rate of either 900 (n = 5) or 600 (n = 7) μU/kg/min (1.9 or 1.2 ng/kg/min) in physiologic saline solution for 5 of every 30 minutes. Fetuses in the control group (group 1) received saline solution at the same flow rate and pulse regimen beginning at 127 ± 1 days' gestational age. Infusions were continued for 6 days.

Blood sampling. Maternal and fetal blood samples were drawn into sterile chilled syringes and centrifuged at 4° C; plasma was immediately flash frozen in liquid nitrogen. Fetal and maternal blood gases were determined with 0.5 ml blood in an ABL2 Acid Base Laboratory (c version; Radiometer A/S, Copenhagen). Maternal and fetal plasma (0.5 ml) for measurement of cortisol concentrations was taken twice daily before the start of a pulse, but not during a contracture. Sampling was possible in one animal for 5 days of the experimental period; all other animals were sampled for 6 days of the experimental period for cortisol measurement. In 17 sheep from the two groups a frequent sampling protocol was carried out to overcome potential problems of pulsatile fetal corticotropin secretion. Plasma (0.7 ml) for measurement of fetal corticotropin levels was taken every 5 minutes for a 60-minute period at 4 PM ± 2 hours (mean ± SD) on 1 baseline day and on another day during the periods 1 to 4 and 5 to 8 days after start of pulsatile infusion. This resulted in 12 samples from 1 day. Fetal blood was handled aseptically and the erythrocytes returned at the end of the day's sampling.

Cortisol radioimmunoassay. Plasma cortisol concentration was measured (Autopak cortisol kit, Micromedic Systems Inc., Horsham, Pa.) as previously described.[10] Twenty microliters of plasma was extracted with the dichloromethane method[11] and assayed in antibody-coated tubes (antibody raised against histamine-3-cortisol). Maternal plasma extraction efficiency is slightly higher (89%, n = 24) than fetal (86%, n = 24). Values obtained from the assay were corrected for recovery. Intraassay coefficients of variation were 9.0% for the maternal pool (mean concentration 68.7 ng/ml, n = 24) and 10.0% for the fetal pool (mean concentration 13.3 ng/ml, n = 10). With a different set of pools, the interassay coefficient of variation was 18.3% for the maternal pool (mean concentration 45.5 ng/ml, n = 9) and 22.6% for the fetal pool (mean concentration 19.5 ng/ml, n = 9). The range of the standard curve was 0.96 to 64 ng/ml for the plasma samples. Assay sensitivity, calculated as the upper value of 95% confidence interval of bound/unbound, was 0.9 ng/ml of sample.

Immunoreactive corticotropin radioimmunoassay. Plasma corticotropin was measured (INC Star corticotropin kit, Stillwater, Minn.). The method we described previously was miniaturized.[12] Plasma was thawed on ice and 50 μl plasma was incubated with rabbit antihuman corticotropin (fragment 1-24) antiserum for 24 hours at 4° C, and then incubated with iodinated corticotropin (fragment 1-24) for another 24 hours at 4° C. The bound fraction was precipitated with a goat antirabbit second antibody. Interassay coefficients of variation for fetal pool (mean concentration 28.8 pg/ml, n = 9) were 12.5% and for maternal pool (mean concentration 42.8 pg/ml, n = 8) were 8.2%. Intraassay coefficients of variation for fetal and maternal pools were 6.1% and 3.0% respectively. Assay sensitivity, calculated as the 90% bound/unbound limit of detection was 5.0 pg/ml of sample.

Myometrial electromyogram, data acquisition, and analysis. The recording of myometrial electromyographic activity was performed continuously for 8 days, integrated over 8-second intervals, and analyzed as previously described.[13] Twenty-four–hour analysis periods commenced with the first oxytocin or saline solution pulse at 4 PM ± 2 hours (mean ± SD). Total myometrial electromyographic activity is the algebraic sum of electromyogram peak height (voltage) at each 8-second interval during the 24-hour period.

Statistical analysis. Myometrial electromyogram val-

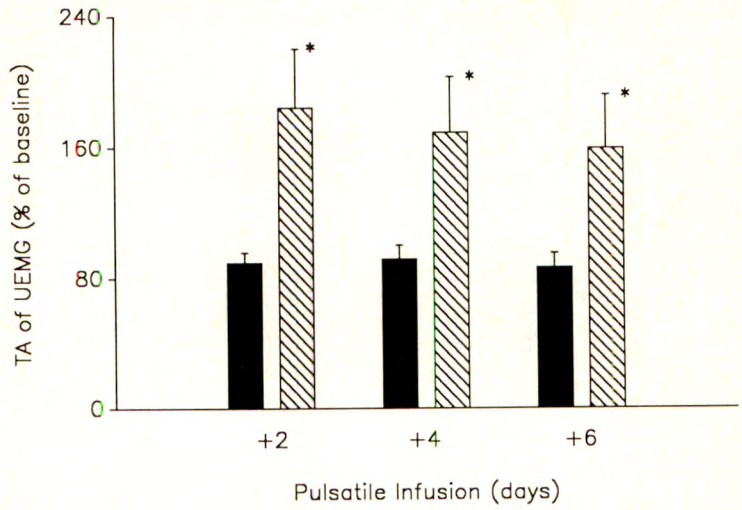

Fig. 1. Total activity *(TA)* of myometrial electromyogram *(UEMG)* (mean ± SEM) as percent of baseline in control fetuses (group 1, $n = 8$, *solid bar*) and fetuses of oxytocin-pulsed ewes (group 2, $n = 6$, *striped bar*) on days 2, 4, and 6 after the start of the pulsatile infusion regimen. Split plot analysis was performed with a set of orthogonal contrasts to compare values in the two groups at each time point. *Asterisk*, $p < 0.05$.

ues were normalized and are presented in the form of percentage of the mean on the 2-day baseline period (experimental day activity/baseline activity × 100). For example, 160% of baseline represents a 60% increase above baseline. Fetal plasma cortisol concentrations were log transformed for analysis. Split plot analysis was performed with a set of orthogonal contrasts to compare values at each time point. Significance is given at $p < 0.05$ level. Data throughout are given as mean ± SEM.

A one-sided t test (where group 2 > group 1 was expected) of fetal plasma corticotropin values was performed with the mean of the 12 samples in each series, the coefficient of variation, and the maximum and minimum corticotropin value observed in each 12-sample series. Groups 1 and 2 were compared at baseline and at 1 other day during the periods of 1 to 4 and 5 to 8 days after the start of pulsatile infusion. Significance is given at $p < 0.05$ level.

Results

Blood gases. Fetal carotid arterial Po_2 was 22.6 ± 0.6 mm Hg in group 1 and 20.0 ± 0.9 mm Hg in group 2 over the 3 to 6 days before commencement of infusion. By day 6 of infusion, fetal Po_2 remained unchanged in group 1 (21.9 ± 1.1 mm Hg) and had fallen significantly in group 2 (18.0 ± 0.9 mm Hg), $p < 0.05$. Maternal blood gases on the baseline day were Po_2 99.6 ± 5.1 mm Hg and pH 7.47 ± 0.01 for group 1 and Po_2 102.8 ± 4.0 mm Hg and pH 7.45 ± 0.02 for group 2; these did not change throughout the study. The blood gas analyzer was not operational at some periods; thus complete data were available for analysis from only seven fetuses in group 1 and eight fetuses in group 2.

Myometrial electromyographic data. Total myometrial electromyographic activity was increased ($p < 0.05$) in group 2 ($n = 6$; the electromyograms of two individual animal preparations were monitored continuously on a polygraph to confirm increased activity, but they were not stored in the computer for analysis) for all days as compared with the corresponding days in group 1 ($n = 8$) (Fig. 1). Data in this figure are normalized to baseline values equal to 100%. The duration of individual contractures did not change throughout the study in either group 1 or 2. In group 1 contractures lasted 391.8 ± 59.3 seconds before saline solution pulses and 375.4 ± 69.4 seconds on day 4 of pulsatile saline solution administration. In group 2 contractures lasted 359 ± 59.0 seconds before oxytocin pulses were started and 333.3 ± 65.8 seconds on day 4 of oxytocin administration.

Cortisol. Maternal carotid arterial plasma cortisol concentrations were not different between the two groups during the baseline period (group 1, 10.0 ± 1.8 ng/ml, group 2, 5.9 ± 0.8 ng/ml) and did not change during the experimental period. On day +6 maternal plasma cortisol for group 1 was 6.8 ± 1.6 ng/ml, and for group 2 was 5.3 ± 0.8 ng/ml. Fetal carotid plasma cortisol concentrations were significantly elevated in group 2 by days 4 and 6 ($p < 0.05$) (Fig. 2). Baseline and day 6 cortisol values for group 1 fetuses were 4.4 ± 1.3 and 6.1 ± 1.7 ng/ml, respectively, and those for group 2 fetuses were 4.5 ± 1.6 and 12.5 ± 2.3 ng/ml, respectively ($p < 0.05$). Ten individual fetal preparations were used for group 1 except for the day

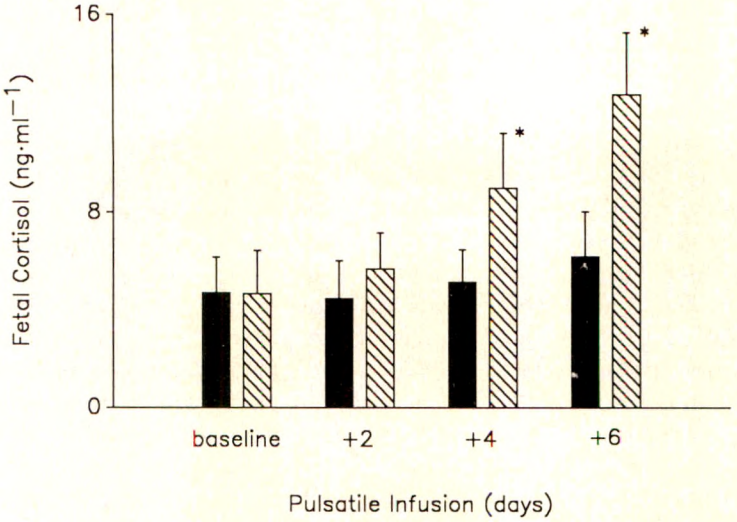

Fig. 2. Fetal arterial plasma cortisol concentrations (mean ± SEM) in control fetuses (group 1, $n = 10$, *solid bar*) and fetuses of oxytocin-pulsed ewes (group 2, $n = 12$, *striped bar*) on baseline and days 2, 4, and 6 after the start of the pulsatile infusion regimen. Split plot analysis was performed with a set of orthogonal contrasts to compare values in the two groups at each time point. *Asterisk*, $p < 0.05$.

Table I. Analysis of fetal arterial plasma corticotropin concentrations

Group	*Days of infusion*	*Fetal plasma corticotropin values (pg/ml)*	*Coefficient of variation (%)*	*Maximum fetal plasma corticotropin values (pg/ml)*	*Minimum fetal plasma corticotropin values (pg/ml)*
Saline ($n = 7$)	Baseline	13.2 ± 2.2	39.9 ± 19.1	20.3 ± 2.5	9.2 ± 2.2
Oxytocin ($n = 10$)		14.4 ± 2.6	47.5 ± 18.6	20.6 ± 3.3	9.8 ± 2.1
Saline	1-4	19.8 ± 3.9	22.0 ± 7.1	32.3 ± 11.1	14.1 ± 2.0
Oxytocin		18.8 ± 3.0	39.4 ± 11.7	28.5 ± 4.0	12.3 ± 2.5
Saline	5-8	19.5 ± 3.9	19.8 ± 4.1	26.8 ± 5.1	14.8 ± 3.6
Oxytocin		23.5 ± 4.6	31.7 ± 8.0	35.2 ± 8.6	13.8 ± 3.8

Twelve samples were taken at 5-minute intervals from each fetus on a baseline day and one other day during the periods 1 to 4 and 5 to 8 days after start of the pulsatile infusion regimen. Values are mean ± SEM. There were no significant differences between groups.

6 sample, in which one fetus's samples were not obtained. Twelve individual fetal preparations were used for group 2 except for the day 4 and 6 samples, in which one fetus's samples were not obtained.

Corticotropin. Table I shows the mean fetal plasma corticotropin, coefficient of variation, and maximal and minimal values in both groups during the 1-hour frequent sampling bout on the baseline day, 1 day in the 1- to 4-day window, and 1 day in the 5- to 8-day window after the start of pulses. None of the fetal carotid plasma corticotropin variables were different between the two groups at any of the time periods.

Comment

Our intention in choosing the oxytocin-infusion regimen was to increase myometrial activity only to the higher end of the range normally seen in pregnant sheep, thus keeping our investigation of fetal adrenal function within physiologic limits. Myometrial electromyographic activity was increased to 160% of baseline in group 2. The pulsatile oxytocin infusion regimen used in group 2 delivered a lower amount of oxytocin to the ewe than the regimens used by other investigators.[7] Oxytocin infusion (960 μU/kg/min) resulted in a peak maternal uterine vein oxytocin plasma concentration of 70 pg/ml at the end of the 5-minute pulse. Maternal uterine vein plasma oxytocin concentration was back to baseline (20 pg/ml) by 15 minutes from the start of the pulse.[9] Because oxytocin does not cross the ovine placenta,[14] oxytocin's effect on fetal cortisol concentrations must be produced indirectly via changes in the ewe or placenta.

Our study was designed to test the hypothesis that increased myometrial activity would result in evidence

of increased fetal adrenal activity. The increased fetal plasma cortisol concentrations may have been caused by one or more of a variety of intermediary mechanisms. We and others have shown that myometrial contractures are associated with both increased sensory stimulation to the fetus[1] and decreased uterine blood flow, which leads to a fall in fetal arterial P_{O_2}.[4] The alterations of fetal chest wall diameters that take place during contractures show that the fetus is deformed to a varying extent by individual contractures.[1] This influence on the fetus should be accentuated by the increase in total uterine contractility produced by oxytocin administration in group 2. Although the fetal P_{O_2} decreased in group 2 fetuses, this level of arterial P_{O_2} would still be considered healthy, suggesting that the increased uterine contractility did not compromise the fetus. It has been shown that mild levels of fetal hypoxia slightly greater than those seen here (a decrease of <5 mm Hg from baseline) maintained for 24 hours were accompanied by elevated plasma cortisol values in fetal sheep (122 to 139 days' gestational age).[15] Further studies in which the effects of contractures on fetal shape and oxygenation are controlled during oxytocin administration will be necessary to determine which of these two stimulatory pathways are involved.

Fetal plasma cortisol levels show considerable variation over a 90-minute period.[16] Our study samples were taken with the intent of minimizing variation related to myometrial activity by avoiding periods of myometrial activity and sampling just before administration of an oxytocin pulse. The increase in fetal plasma cortisol concentrations observed in the group 2 fetuses resembles the beginning of the normal predelivery rise seen at about 136 to 140 days' gestational age.[8] Fetal plasma cortisol concentrations in both groups are considerably lower than concentrations seen immediately before spontaneous[8] or corticotropin-induced[17] parturition, and also less than those seen in fetuses of the same gestational age in conditions of a 2-hour hypoxemic[18] or 10-minute hypotensive[19] stress. Thus the changes in fetal cortisol seen on day 4 and day 6 of oxytocin administration were within the physiologic range.

We were unable to show an increase in mean fetal plasma immunoreactive corticotropin levels accompanying the increased fetal plasma cortisol concentrations in the fetuses of oxytocin-infused ewes. Nor could we show a change in fetal release of corticotropin based on coefficient of variation of each series or maximum and minimum values. These indices reflect the overall variability and range of this variability under each treatment. It is possible that the oxytocin-induced contractures influence fetal adrenal cortisol secretion via nonpituitary mechanisms. We have shown that bilateral splanchnic nerve section of the fetal lamb in late gestation will significantly lower the rise in fetal plasma cortisol concentrations in response to hypotension in the absence of any change in the rise in fetal plasma corticotropin.[20] Thus sensory stimulation of the fetus by contractures may affect neural mechanisms that influence adrenocorticol and medullary function via the splanchnic nerves. It is now apparent that interrelationships exist between the adrenal cortex and the medulla.[21] Other potential mechanisms for stimulation of the increased fetal plasma cortisol we observed are increased prostaglandin production,[22] corticotropin from the placenta,[23, 24] or another source that is bioactive but not immunoreactive in our assay. Prostaglandin E_2 has been implicated in the stimulation of a rise in fetal adrenal cortisol production directly without a concomitant rise in corticotropin.[22]

In conclusion, these data show that fetal plasma cortisol concentration in late gestation is elevated in response to increased myometrial activity associated with a small but statistically significant fall in fetal carotid arterial P_{O_2}. Because the increase in total myometrial contractility was within physiologic limits, these results are compatible with the view that the fetus responds to signals from the mother that may act through altered myometrial activity. These findings also have implications in physiologic and clinical conditions in which the extent of stimulation of contractures is altered as in oligohydramnios or polyhydramnios.

We thank Karen Moore for her excellent assistance with this manuscript.

Editors' note

The American Journal of Obstetrics and Gynecology introduces a new format for abstracts accompanying regular articles, society articles, and Current Investigation articles. Authors submitting these manuscripts to the Journal should provide an abstract of no more than 150 words structured according to the following headings: Objective(s), Study Design, Results, and Conclusion(s). Exceptions to this requirement include Clinical Opinion, Current Development, case report, and brief communication articles. Abstracts for these articles will continue to follow the standard abstract format. Please consult the Information for Authors for details.

Both 17β-estradiol and tamoxifen induce c-*fos* messenger ribonucleic acid expression in human endometrial carcinoma grown in nude mice

Katsumi Sakakibara, MD,[a] Nancy C. Kan, PhD,[b] and Pondichery G. Satyaswaroop, PhD[a]
Hershey, Pennsylvania

We previously demonstrated the estrogen-like effects of tamoxifen on the acceleration of growth and increased progesterone receptor concentrations of human endometrial carcinomas grown in the nude mouse experimental model. In our current study the modulation of protooncogene expression by 17β-estradiol and tamoxifen in human endometrial carcinomas was investigated. The protooncogenes investigated in this study were c-*fos*, c-*jun*, c-*myc*, N-*myc*, HER-2/*neu*, c-*erb*B, c-*fms*, and c-Ha-*ras*. Among those we found that c-*fos* expression was induced by 17β-estradiol in the following 17β-estradiol–sensitive tumors: EnCa-101 and EnCa-X. The induction was apparent within 1 hour, reached peak level at 2 hours (16-fold), and remained constant up to 4 hours. The c-*fos* messenger ribonucleic acid returned to prestimulation level by 12 hours. Tamoxifen also stimulated c-*fos* expression, the expression pattern being similar to that of 17β-estradiol albeit of a lesser degree. The messenger ribonucleic acid transcripts for other protooncogenes tested did not show significant changes during hormonal manipulation. The induction of c-*fos* expression by tamoxifen is consistent with its estrogen-like effect on endometrial carcinoma growth. (Am J Obstet Gynecol 1992;166:206-12.)

Key words: Tamoxifen, estradiol, endometrial carcinoma, protooncogenes, mRNA expression

A series of human endometrial carcinomas displaying different degrees of steroid hormone responsiveness in the nude mouse model has been established.[1, 2] Two of these established, well-differentiated endometrial carcinomas, EnCa-101 and EnCa-X, are steroid receptor positive and responsive to 17β-estradiol (E_2) and progesterone. As observed in normal endometrium E_2 stimulates growth and increases progesterone receptor, and progesterone inhibits growth and induces secretory changes in these tumors.[3, 4] Tamoxifen, a synthetic triphenylethylene compound, exhibited E_2-like effects in these tumors with regard to increased growth and progesterone receptor concentration.[3, 5] The paradoxic effect of tamoxifen on endometrial carcinoma was in contrast to its E_2-antagonistic effect on human breast carcinoma.[6]

The transient expression of immediate, early genes (protooncogenes) was widely reported to be related to cell proliferation-differentiation.[7] Modulation of expression of c-*fos*, c-*myc*, N-*myc*, c-Ha-*ras*, c-*erb*B, and c-*jun* by E_2 has been demonstrated in rodent uterus, chick oviduct, and human breast carcinoma cells in culture.[8-15] To ascertain whether the growth-stimulatory effect of tamoxifen on endometrial carcinoma was reflected in its effects on these immediate, early genes we studied the effects of E_2 and tamoxifen on the expression of various protooncogenes in EnCa-101. The effects of E_2 and tamoxifen in an E_2-insensitive, poorly differentiated endometrial carcinoma, EnCa-138, were compared in parallel.

Material and methods

Materials. The following materials were used: E_2, tamoxifen, and placebo pellets (Innovative Research of America, Toledo); α-phosphorus 32 2′-deoxycytidine-5′-triphosphate (dCTP) (Amersham, Inc., Arlington Heights, Ill.), guanidinium thiocyanate, oligo dT-cellulose, and random-primed deoxyribonucleic acid (DNA)–labeling kit (Boehringer Mannheim Biochemical, Indianapolis); sodium acetate, sodium chloride, dextran sulfate sodium salt, sodium dodecyl sulfate (SDS), sodium citrate, and salmon sperm DNA (Sigma Chemical Co., St. Louis); cesium chloride, formamide, and restriction endonucleases (Bethesda Research Laboratories, Gaithersburg, Md.); nylon membranes (Schleicher and Schuell, Inc., Keene, N.H.); oncogene probes v-*fos* (p*fos*-1), N-*myc* (pNB-1), HER-2/*neu* (pHER-2-436-1), c-Ha-*ras* (*pbc*-N1), v-*fms* (pSM7C), and

v-*erb*B (pAE*Bam*-R1) (American Type Culture Collection, Rockville, Md.); complementary DNA (cDNA) clone pHJ40 (c-*jun*) (Dr. Robert Tjian, University of California, Berkeley); and β-actin cDNA (Dr. George Oyler, The Pennsylvania State University).

Animals. Four- to five-week-old male BALB/c, nu/nu nude mice (Harlan Sprague Dawley, Inc., Indianapolis) were maintained in separate barrier facilities used exclusively for these animals. They were castrated at least a week before use.

Tumor transplantation and growth. The E_2- and tamoxifen-sensitive tumors (EnCa-101 and EnCa-X) and insensitive tumor (EnCa-138) were derived from primary carcinomas of human endometrium by serial transplantation in the nude mouse model.[2] EnCa-101 is a histologically well-differentiated adenocarcinoma, and EnCa-138 is a poorly differentiated adenosquamous carcinoma. Tumor tissues (~20 mg) were transplanted subcutaneously in the infrascapular and lumbar regions at four sites of 4- to 6-week-old, castrated, athymic BALB/c, nu/nu nude mice. The animals were divided into three groups (three mice per group): group 1, control pellets (cholesterol, methylcellulose, lactose matrix); group 2, E_2 pellets (blood level maintained at 200 pg/ml for 60 days); group 3, tamoxifen pellets (blood level maintained at 20 to 30 ng/ml for 60 days). These pellets were implanted into mice subcutaneously. Growth rate of the tumors was monitored by determining tumor volume with a vernier calipers at weekly intervals.

Protooncogene messenger ribonucleic acid (mRNA) expression. For protooncogene mRNA expression studies, the tumors were grown without implants. When the tumors reached 8 mm in geometric mean diameter, the animals were implanted with E_2 or tamoxifen pellets subcutaneously (n = 4). The tumors were removed at 0, 0.5, 1, 2, 4, 6, 12, and 24 hours thereafter. Three separate experiments were carried out with essentially similar results.

Northern blot analysis. The tumors were pulverized and stored in liquid nitrogen immediately after removal. Ribonucleic acid was prepared as described by Chirgwin et al.[16] Briefly, pulverized tumor samples were homogenized in a solution containing 4 mol/L guanidinium thiocyanate and 25 mmol/L sodium acetate (pH 6.0) (Polytron, Brinkmann Instrument Co., Westbury, N.Y.). After ultracentrifugation through a dense cushion of cesium chloride, total RNA was precipitated by ethanol. Polyadenylic acid [poly(A)]–positive RNA was isolated by affinity chromatography with oligo(dT) cellulose.[17] Two to five micrograms of poly(A)–positive RNA was denatured at 95° C for 2 minutes, fractionated in 1% agarose gels containing 0.66 mol/L formaldehyde, and transferred to nylon membranes in 10× SSC (1.5 mol/L sodium chloride, 0.15 mol/L sodium citrate dehydrate). Nylon membranes were baked at 80° C for 2 hours and prehybridized for 3 to 12 hours at 42° C in a solution containing 50% deionized formamide, 1% SDS, 1 mol/L sodium chloride, and 10% dextran sulfate. Thereafter hybridization was performed for 16 to 18 hours at 42° C in the prehybridization buffer containing sonicated and denatured salmon sperm DNA (50 μg/ml) and 1.0 × 10^6 cpm ^{32}P-labeled DNA probe per milliliter (specific activity 1 to 2 × 10^9 cpm/μg DNA). The DNA probes were labeled with α-^{32}P dCTP with random-primed DNA-labeling kit. After hybridization, nylon membranes were washed as follows: twice in 2× SSC at room temperature for 5 minutes, twice in 2× SSC and 1.0% SDS at 65° C for 30 minutes, and twice in 0.1× SSC at room temperature for 30 minutes.

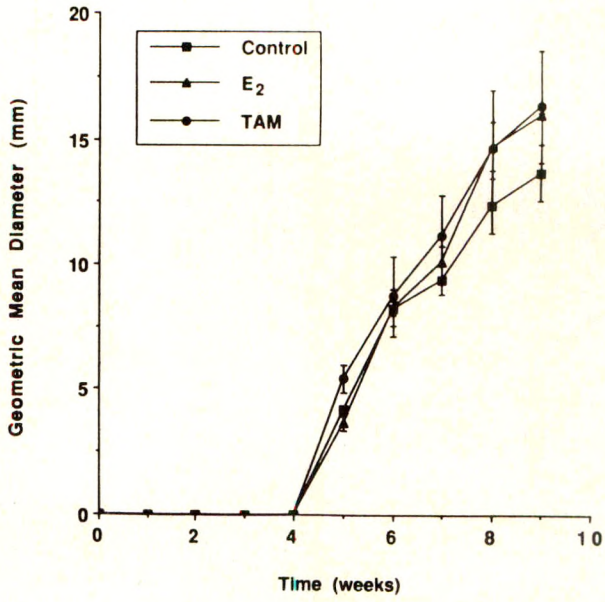

Fig. 1. Tumor-growth study of poorly differentiated EnCa-138 endometrial carcinoma. Animals bearing EnCa-101 tumors received placebo, E_2, 1.7 mg or tamoxifen (*TAM*, 5 mg) pellets. Growth rate of the tumors was monitored weekly by determining tumor size with vernier calipers. Results were expressed as mean; *bars*, SD (control, n = 12; tamoxifen, n = 12; E_2, n = 8).

The nylon membranes were exposed to film (Kodak X-AR5, Eastman Kodak, Rochester, N.Y.). The probe was removed by washing the membranes with 0.01× SSC and 0.01% SDS at 95° C several times for a few minutes. Autoradiography was performed to verify removal of the probe, and the membranes were hybridized to a second probe. Autoradiograms were scanned by a laser densitometer (Protein Databases, Inc., Huntington Station, N.Y.) to determine relative levels of protooncogene expression.

Radioimmunoassay of serum E_2. Male BALB/c mice (n = 22) were castrated 1 week before the study. Eigh-

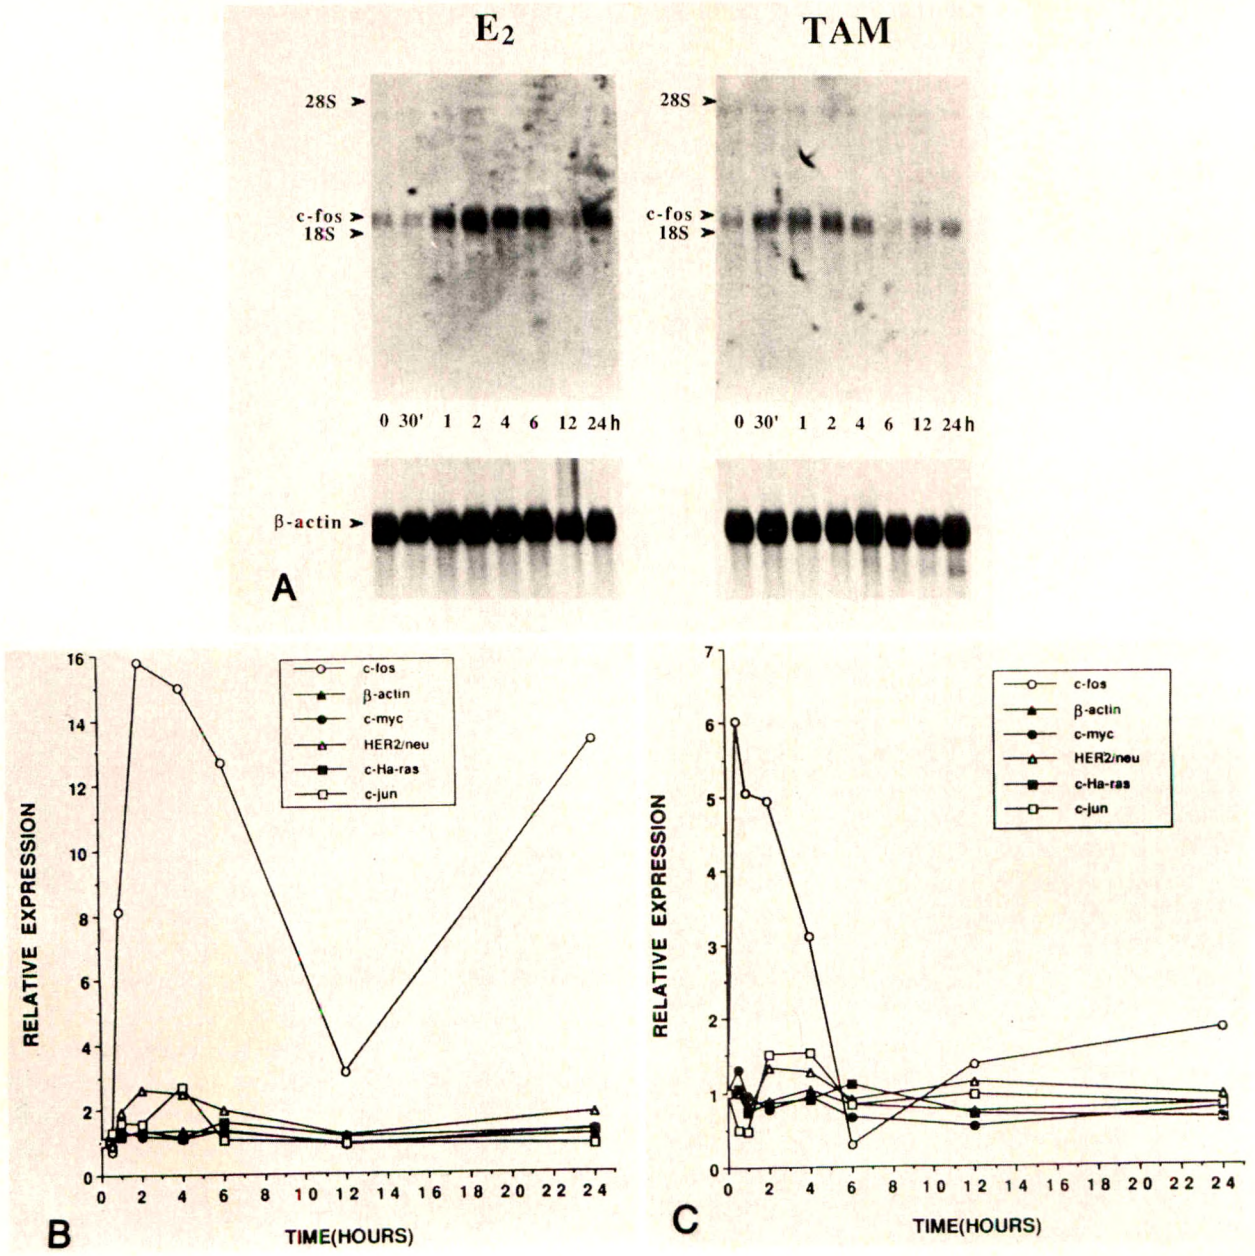

Fig. 2. A, Northern blot analysis of c-*fos* mRNA expression by E_2 and tamoxifen *(TAM)* in EnCa-101. Well-differentiated EnCa-101 tumors grown in nude mice were removed at 0, 0.5, 1, 2, 4, 6, 12, and 24 hours after subcutaneous E_2 or tamoxifen pellet implantation. Each lane was loaded with 2.0 μg poly(A)$^+$ RNA fractionated in 1.0% agarose gel with 0.66 mol/L formaldehyde transferred to a nylon membrane and hybridized with a v-*fos* probe. *Left panel,* c-*fos* mRNA expression by E_2; *right panel,* c-*fos* mRNA expression by tamoxifen; *bottom panel,* β-actin mRNA expression on same nylon membrane. Membrane hybridized with v-*fos* probe was exposed for 90 hours and with β-actin probe for 2 hours. **B,** Relative expression of protooncogene mRNA in EnCa-101 by E_2 was calculated by densitometric scanning of autoradiographs shown in Figs. 2, *A*, 4, *A*, and 5. Only major 2.7 kb c-*jun* band was scanned and used in the analysis. **C,** Relative expression of protooncogene mRNA in EnCa-101 by tamoxifen was calculated by densitometric scanning of autoradiographs shown in Figs. 2, *A*, 4, *A*, and 5. Data of major 2.7 kb c-*jun* band were used in analysis.

teen mice were subcutaneously implanted with a 1.7 mg E_2 pellet. Four mice received no pellets and served as controls. After E_2 pellet implantation, blood (200 μl) was removed from the retroorbital sinus at indicated time periods. Serum levels of E_2 were determined by radioimmunoassay.

Results

Effect of E_2 and tamoxifen on poorly differentiated EnCa-138 growth. We previously reported on the growth-promoting effects of E_2 and tamoxifen on the E_2-sensitive tumors EnCa-101 and EnCa-X.[2-4] In the present study the growth rate of the poorly differen-

tiated EnCa-138 tumor in nude mice was investigated (Fig. 1). EnCa-138 tumor grew rapidly, and administration of E_2 or tamoxifen did not alter the growth rate. All tumors were devoid of E_2 or progesterone receptors by ligand binding assay (results not presented).

Serum E_2 levels in nude mice subcutaneously implanted with E_2 pellets. In the nude mouse system E_2 and other agents were delivered to the animals continuously by subcutaneous implants of pellets. E_2 pellet was designed to maintain a serum level of 200 to 300 pg/ml over a 60-day period. Thirty minutes after pellet implantation, E_2 levels in serum reached 13 ng/ml and the level was maintained for the next 6 hours. Thereafter E_2 concentration varied between 2.7 and 5 ng/ml for 7 days (Table I).

Induction of c-*fos* mRNA by E_2 and tamoxifen in EnCa-101. To study the effects of E_2 and tamoxifen on immediate, early genes, we examined c-*fos* mRNA expression in E_2- and tamoxifen-sensitive EnCa-101. After E_2 administration a significant induction (Fig. 2, *A* and *B*) was apparent within 1 hour (eightfold) and reached peak level (16-fold) at 2 hours. It was maintained for at least 4 hours, followed by a rapid decrease at 12 hours. C-*fos* mRNA expression was restimulated and reached a high level (13-fold) at 24 hours. Long-term study indicated that c-*fos* expression appeared to by cyclic (not shown). A similar pattern was observed in another steroid receptor-positive, E_2- and tamoxifen-sensitive tumor, EnCa-X, with both E_2 and tamoxifen treatments (not shown). Tamoxifen also induced c-*fos* mRNA expression in EnCa-101 (Figs. 2, *A* and *C*). This induction was more rapid and short-lived than that by E_2. The maximal induction occurred at 30 minutes, and c-*fos* mRNA decreased to below basal level at 6 hours. The peak c-*fos* mRNA level was lower than that obtained with E_2. At 24 hours, c-*fos* mRNA returned to basal level.

Effects of E_2 and tamoxifen on c-*fos* mRNA expression in EnCa-138. To investigate whether c-*fos* mRNA induction was mediated by the steroid hormone pathway, we examined the effects of E_2 and tamoxifen on c-*fos* mRNA expression in the poorly differentiated, steroid receptor-negative, adenosquamous EnCa-138. The steady-state level of c-*fos* mRNA in untreated EnCa-138 tumor was much higher than that in EnCa-101 (Fig. 3). Surprisingly, a small degree of transient induction was observed after E_2 or tamoxifen administration. Within 1 hour of the c-*fos* mRNA level was induced fivefold compared with untreated tumor. It was rapidly decreased to prestimulation levels at 2 hours in E_2-treated tumor and at 4 hours in tamoxifen-treated tumor.

Protooncogene expression in EnCa-101 and EnCa-138. Because c-*fos* and c-*jun* form heterodimers to enhance transcription, we investigated whether c-*jun* mRNA was similarly induced by E_2 and tamoxifen, as was observed with c-*fos*. Hybridization of EnCa-101 and

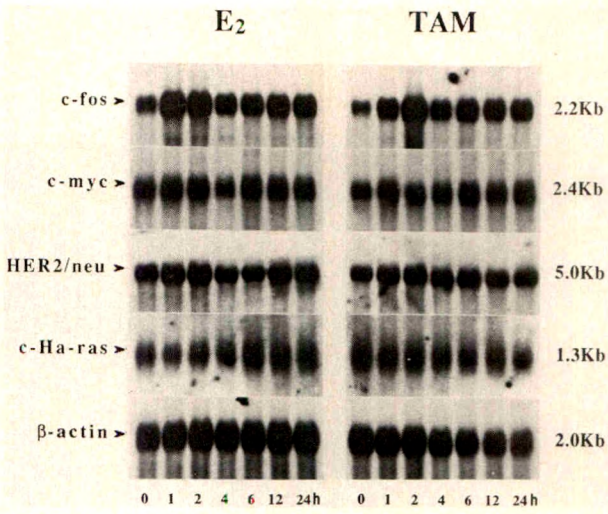

Fig. 3. Northern blot analysis of protooncogene mRNA expression by E_2 and tamoxifen *(TAM)* in EnCa-138. Poorly differentiated EnCa-138 tumors grown in nude mice were removed at 0, 1, 2, 4, 6, 12, and 24 hours after subcutaneous E_2 or tamoxifen pellet implantation. Each lane was loaded with 5.0 μg poly(A) positive RNA. *Left panel,* c-*fos,* c-*myc,* HER-2/*neu,* c-Ha-*ras* and β-actin mRNA expression modulated by E_2; *right panel,* mRNA expression of the same protooncogenes modulated by tamoxifen. Exposure times were as follows: c-*fos,* 20 hours; c-*myc,* 5 hours; HER-2/*neu,* 65 hours; c-Ha-*ras,* 20 hours; and β-actin, 1 hour.

EnCa-138 mRNA with c-*jun* probe showed two bands, a 2.7 kb major species and a 3.3 kb minor species (Fig. 4). Compared with c-*fos* mRNA levels, c-*jun* transcripts were more abundant in untreated tumors of both EnCa-101 and EnCa-138. In EnCa-101, the steady-state levels of c-*jun* mRNA were elevated at 4 hours after E_2 administration (Fig. 4, *A*). In EnCa-138, c-*jun* mRNA appeared to be induced slightly by E_2 and tamoxifen (threefold) (Fig. 4, *B*). The transcripts of other protooncogenes examined either did not show significant changes (c-*myc,* HER-2/*neu,* c-Ha-*ras*) (Fig. 5), were very faint (c-*erb*B not shown), or were undetectable (N-*myc* and c-*fms* not shown).

Comment

The results presented here on the induction of the protooncogene c-*fos* and its expression by E_2 and tamoxifen, provide further support for the E_2-like effects of tamoxifen in human endometrial carcinoma grown in nude mice. We previously reported on the paradoxic, E_2-like effect of tamoxifen on the growth of human endometrial carcinomas EnCa-101 and EnCa-X in the nude mouse model.[3, 5] The c-*fos* mRNA and its protein product, *Fos,* were essentially undetectable in most quiescent cells and attained measurable levels in response to mitogenic stimulation in vitro.[18, 19] Because transcriptional activation of c-*fos* was one of the earliest nuclear events, a role for this oncogene in the cell cycle was suggested.[18, 19] The results of our studies with EnCa-101 in vivo showed that c-*fos* mRNA level

Male BALB/c mice (n = 22) were castrated 1 week before this study. Eighteen mice were subcutaneously implanted with 1.7 mg E_2 pellets and four mice were left free of implants. Blood (200 μl) from groups (n = 3) of mice was removed from retroorbital sinus at indicated times after E_2 pellet implantation. Serum levels of E_2 were measured by radioimmunoassay in individual samples and expressed as mean ± SEM.

was very low or undetectable in the absence of E_2; its induction became evident within 1 hour, reached peak level at 2 hours, and this level was maintained until 4 hours. Interestingly, the c-*fos* expression pattern induced by tamoxifen was similar to that by E_2, although the peak level attained with tamoxifen (sixfold) was lower than that with E_2 (16-fold). It is noteworthy that under identical growth conditions in our experimental system the growth rate of EnCa-101 induced by E_2 was significantly higher than that observed with tamoxifen.

Although the sequence of events involved in E_2-mediated induction of c-*fos* is unclear, it is possible that E_2–estrogen receptor complex binds to specific estrogen response elements to regulate c-*fos* expression.[20] Tamoxifen–estrogen receptor complex may bind to estrogen response elements in a similar fashion, resulting in modulation of c-*fos* expression. An estrogen response element upstream of human c-*fos* gene that binds estrogen receptor and activator protein 1 transcription factor has been identified.[21] Recently, activation of the

ovalbumin gene by the estrogen receptor was shown to involve the *Fos-Jun* complex.[22] Several recent studies have demonstrated that formation of *Jun-Fos* heterodimers resulted in a remarkable increase in its affinity to activator protein-1 recognition sequence to initiate transcription. In contrast, *Fos* does not appear to form homodimers and is ineffective in binding to specific DNA sequences by itself.[23-25] We observed a relatively higher level of c-*jun* mRNA in EnCa-101 under basal conditions. Exposure to E_2 resulted in a twofold to threefold increase at 4 hours in this system (Fig. 4, *A*). It is conceivable that once c-*fos* protein synthesis occurs in response to E_2, it could instantly form heterodimers with the relatively abundant *Jun* and initiate the sequence of events that mediate the growth-promoting effect of E_2 in EnCa-101. Thus the rapid and transient expression of c-*fos* may be the regulatory step. In contrast to E_2 tamoxifen induced a transient decrease in c-*jun* expression in our study, although significant levels of c-*jun* transcripts were still present at these early time points (Fig. 4, *A*).

EnCa-138 tumor was chosen as a negative control because its growth was unaffected by E_2 and tamoxifen (Fig. 1). Surprisingly, both E_2 and tamoxifen exhibited rapid and transient induction of c-*fos* mRNA in this tumor. However, in contrast to EnCa-101, in which c-*fos* basal level was very low or virtually undetectable, EnCa-138 contained a relatively high level of c-*fos* mRNA in the absence of E_2 or tamoxifen (Fig. 3). The basal level of c-*jun* transcripts was also high and further stimulated twofold to fourfold in the presence of E_2 and tamoxifen (Fig. 4, *B*). A relatively faster growth rate of EnCa-138 compared with EnCa-101 in the nude mouse and the inability of E_2 and tamoxifen to further increase the growth rate of this tumor could explain the higher basal levels of both c-*fos* and c-*jun* mRNA and presumably their protein products.

Recently induction of c-*fos* and c-*jun* mRNA expression by E_2 was reported in the rodent uterus. In addition, expression of other protooncogenes c-*myc*, N-*myc*, c-Ha-*ras* and c-*erb*B was also shown to be modulated by E_2 in rat uterus and human breast carcinoma cell lines.[8-15] We tested eight protooncogenes, c-*fos*, c-*jun*, c-*myc*, N-*myc*, HER2/*neu*, c-*erb*B, c-*fms*, and c-Ha-*ras*. Among them, E_2- and tamoxifen-modulated expression of c-*fos* was several-fold compared with the others examined in the steroid hormone–responsive, well-differentiated EnCa-101.

In summary, we have shown that E_2 transiently enhanced the steady-state levels of c-*fos* mRNA and c-*jun* expression was modulated to a lesser degree by E_2 in human endometrial carcinoma in vivo. The pattern of c-*fos* expression induced by tamoxifen was similar to that observed with E_2. The effect of tamoxifen on immediate early protooncogene expression observed in our study is in accord with its growth-promoting role in human endometrial carcinoma and further distinguishes it as an estrogen agonist in this tissue.

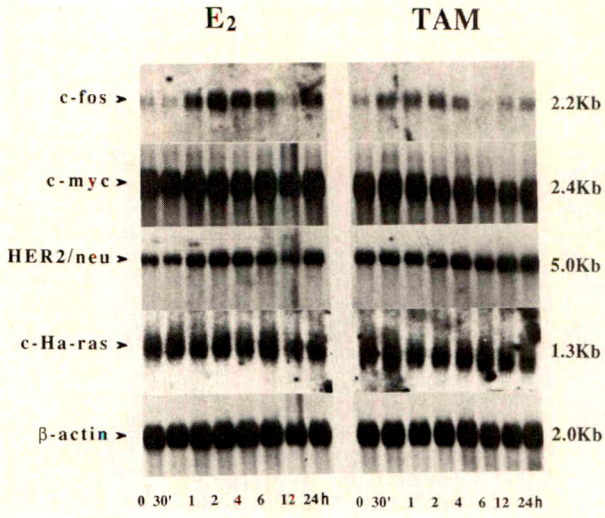

Fig. 5. Northern blot analysis of protooncogenes mRNA expression by E_2 and tamoxifen *(TAM)* in EnCa-101. Same RNA samples analyzed in Fig. 2, *A*, were hybridized to c-*myc*, HER-2/*neu*, and c-Ha-*ras* probes individually. *Left panel* shows c-*fos*, c-*myc*, HER-2/*neu*, c-Ha-*ras*, and β-actin mRNA expression modulated by E_2; *right panel* shows same protooncogene mRNA expression modulated by tamoxifen. Exposure times for autoradiographs were as follows: c-*fos*, 90 hours; c-*myc*, 20 hours; HER-2/*neu*, 20 hours; c-Ha-*ras*, 65 hours; and β-actin, 2 hours.

We thank Shane Miller, Robert Lorinc, and Arunthathy Sivarajah for their skilled technical help, and Barbara S. Hynum and Lorraine A. Pace for the preparation of this manuscript.

Low-dose infusion of atrial natriuretic peptide in the conscious guinea pig increases blood flow to the placenta of growth-retarded fetuses

Thomas B. Jansson, MD, PhD
Göteborg, Sweden

OBJECTIVE: Our goal was to investigate the effects of low-dose infusion of atrial natriuretic peptide on maternal placental blood flow of normal-sized and growth-retarded fetuses.
STUDY DESIGN: Seventeen conscious, chronically catheterized guinea pigs were studied at day 50 of gestation after growth retardation was experimentally induced by unilateral uterine artery ligation at day 34.
RESULTS: In 12 experiments atrial natriuretic peptide infusion (15 ng/kg/min) increased blood flow (microsphere technique) to placentas of growth-retarded fetuses by 26% ($p < 0.01$) while placental blood flow of normal-sized fetuses remained unchanged. This difference in responsiveness to atrial natriuretic peptide infusion was statistically significant ($p < 0.001$). Blood pressure, heart rate, and myoendometrial and renal blood flows were unaffected. Plasma concentrations of immunoreactive atrial natriuretic peptide increased by 64%, indicating that physiologic concentrations were achieved. In five saline solution–treated controls none of the studied parameters changed.
CONCLUSION: Atrial natriuretic peptide in low doses selectively increases blood flow to placentas of growth-retarded fetuses in the conscious guinea pig. Infusion of atrial natriuretic peptide in a dose that results in plasma concentrations within the upper physiologic range may have a therapeutic value in pregnancies complicated by intrauterine growth retardation. (Am J Obstet Gynecol 1992;166:213-8.)

Key words: Intrauterine growth retardation, placental blood flow, atrial natriuretic peptide, placenta, uteroplacental vasculature

Except for estrogens,[1] few substances have been shown to dilate the maternal vessels supplying the placenta in late pregnancy. Although it may be argued that the placental vascular bed is maximally dilated near term, it was recently demonstrated that stimulation of adenylate cyclase by forskolin dilates the vessels of the near-term ovine placenta.[2]

Systemic administration of a potent vasodilator in pharmacologic doses decreases blood pressure and inevitably elicits increased levels of circulating catecholamines. Because uteroplacental vessels are highly sensitive to the vasoconstricting effects of norepinephrine,[3,4] the possible vasodilating effects of the substance will be counteracted, making interpretation of results difficult. This problem can to some extent be circumvented by local administration. However, when such potent endogenous vasodilators as prostacyclin[5] and adenosine[6] were infused close to the uterine artery in the sheep, no placental vasodilation could be demonstrated.

Atrial natriuretic peptide (ANP) is an endogenous substance with diuretic, natriuretic, and hypotensive effects.[7] ANP stimulates insoluble guanylate cyclase, thereby increasing the intracellular levels of cyclic guanosine monophosphate. Circulating levels of ANP have been reported to increase in pregnancy compared with nonpregnant controls,[8] although others have been unable to demonstrate differences.[9] Because ANP is released mainly from the right atrium and acts as a circulating hormone, it is appropriate to administer this peptide systemically to study its physiologic effects. Interestingly, ANP given in high doses dilates the maternal placental vasculature in the late pregnant anesthetized rat[10] and in the near-term sheep.[11] In contrast, in a recent report uterine vascular resistance was unaffected by ANP infusion in the late pregnant sheep.[12]

Pharmacologic doses of ANP elicit cardiovascular effects that are markedly different compared with the effects induced by doses of ANP that result in concentrations within the physiologic range (low dose).[7] The objective of this investigation was therefore to study the effects of low-dose infusions of ANP on placental blood flow in the chronically catheterized conscious guinea pig. An additional purpose was to study whether the

vessels supplying the placenta of growth-retarded fetuses differ in vascular reactivity to ANP.

Material and methods

The investigations described in this paper were approved by the local ethical committee for animal experimentation (170/88).

Seventeen nulliparous albino guinea pig does of the Dunkin-Hartley strain were used. The animals were allowed free access to food (standard pellets and hay) and water (with ascorbic acid, vitamin E, and selenium added). The animals were maintained in an environment of controlled humidity (40% to 70%) and temperature (18° to 20° C), with a 12-hour light-darkness cycle. The day of mating (day 0) was determined by daily inspection of the vaginal membrane. Initially two females and one male guinea pig were housed together; after pregnancy was confirmed by palpation of the fetuses at days 15 to 20 of gestation the does were transferred to a special room in the animal facilities and kept in separate cages. From day 20 until the day of experimentation animals were fed 0.2 to 0.3 ml of water daily from a syringe to accustom them to handling.

At 31 to 38 (34.3 ± 0.4, mean ± SEM) days' gestation the animals were anesthetized with 3% to 4% enflurane and nitrous oxide/oxygen (1 : 1). Under aseptic conditions and temperature control (rectal temperature 37.5° to 38.5° C) a 2 to 3 cm lower abdominal midline incision was made. The mesometrial fat pad of one of the uterine horns was exposed and the uterine artery ligated. The operation lasted 10 to 15 minutes, and the animals were standing up in their cages within 10 minutes of completion.

At 41 to 46 (44.3 ± 0.4) days' gestation, animals were anesthetized with ketamine hydrochloride (30 mg subcutaneously) and xylazine (3 mg intramuscularly), preceded by atropine (0.05 mg subcutaneously). Polyethylene catheters (Becton Dickinson, Parsippany, N.J.) were inserted into the femoral artery and advanced to the aortic bifurcation (PE 25, inner diameter 0.40 mm, connected to PE 90, inner diameter 0.86 mm), into the left ventricle by cannulation of the right common carotid artery in the retrograde direction (PE 50, inner diameter 0.58, connected to PE 90), and into the right external jugular vein (PE 50, connected to PE 90). The catheters were tunneled subcutaneously and exteriorized between the scapulae. A small amount of antibiotic paste (Socatyl vet, Ciba-Geigy, Basel, Switzerland) was applied in the wounds before closure. The operation lasted 30 to 60 minutes. During and after the operation the animals were given a total volume of 30 ml of physiologic saline solution intravenously over 2½ hours. Isoprenaline was added to the fluid for an infusion rate of 1.5 μg/kg/min to preserve cardiac output during anesthesia. Glucose was given (10 mg/kg/min) in the last 20 ml. Catheters were filled with heparinized saline solution and sealed. The animals recovered within 3 to 5 hours after the operation. To maintain patency the femoral artery catheter was flushed with heparinized saline solution every 24 hours.

At least 5 days after the catheterization (49 to 52 days' gestation) experiments were performed in the animal room with the animal freely moving in its own cage without any visual contact with the investigator. After the animal was connected to a swivel it was allowed 2 hours to accommodate to the experimental situation. Throughout the experiment arterial blood pressure and heart rate were measured by means of a pressure transducer (Statham Gould P23 ID, Hato Rey, Puerto Rico) and an oscillation detector, respectively. All recordings were made on a polygraph (No. 7, Grass Instrument, Quincy, Mass.).

Placental blood flow was measured by means of the microsphere technique. Microspheres with a diameter (mean ± SD) of 16.5 ± 0.1 μm and labeled with either niobium 95, ruthenium 103, or cerium 141 (Du Pont, D-6072 Dreieich, Germany) were used. The microspheres were suspended in saline solution with Tween 80. After vigorous vibration with a whirl mixer, 0.6 to 0.7 ml (corresponding to 400,000 spheres) was injected into the left ventricle catheter for 45 seconds; the catheter was then flushed with 1 ml saline solution for 45 seconds. A reference blood sample was withdrawn from the abdominal aorta at a rate of 0.65 ml/min from 10 seconds before the start of the microsphere injection until 75 seconds after the end of flushing. Donor blood was given to compensate for blood loss.

Fifteen minutes after the first microsphere injection, which represents basal blood flows, an intravenous infusion of ANP (15 ng/kg/min, 0.06 ml/min) was started in 12 experiments. ANP (rat sequence, Sigma Chemical Co., St. Louis) was dissolved in physiologic saline solution with bovine serum albumin (0.5 gm/100 ml) added. In five experiments only saline solution with bovine serum albumin was given. Thirty minutes after the start of infusion a second microsphere injection was carried out. In some experiments in the ANP group, blood was obtained from the abdominal aorta immediately after the two microsphere injections for analysis of plasma catecholamine (0.6 ml, n = 10) and ANP concentrations (2 ml, n = 5). Blood samples were promptly transferred to prechilled ethyleneglycol-bis-(β-aminoethylether)-N,N,N′,N′-tetraacetic acid-glutathione– (catecholamines) or ethylenediaminetetraacetic acid–containing (ANP) tubes on ice and subsequently centrifuged (+4° C). Plasma was stored at −50° C until analysis. Blood loss was compensated for with donor blood.

The animal was killed with an overdose of barbiturate. All catheter positions were checked and found

adequate. The uterus was cut between the vagina and cervix and divided through a midline incision of the cervix into the two horns. The uterine horns were opened and the placentas detached from the uterine wall through the separation zone between the subplacenta and the main placenta. Individual placentas and myoendometrium and kidneys were weighed, cut into smaller pieces, and placed into counting vials. The radioactivity of the samples was determined in a multichannel-pulse height analyzer (Packard 5019 connected to Packard 3320, Packard Instrument Co., Inc., Downers Grove, Ill.). Organ blood flows were calculated by the following formula: Organ blood flow (ml/min) = (No. of microspheres in organ/No. of microspheres in reference blood sample) × withdrawal rate (ml/min). No experiment contained fewer than 720 microspheres in placentas, kidneys, or reference blood sample. The lower blood flow (milliliters per minute per gram) of the two kidneys was divided by the higher blood flow value, giving a ratio ≤1.0 for each microsphere injection; the mean ratio was 0.95 ± 0.01 (range 0.83 to 1.0), indicating an adequate mixing of spheres. A specific radioimmunoassay method that included human antibody and guinea pig serum was used to analyze immunoreactive ANP; in other respects the technique was identical to the method described in detail previously.[13] Plasma catecholamine concentrations were analyzed by high-performance liquid chromatography with electrochemical detection.[14]

Results are expressed as mean ± SEM. In cases of more than one normal-sized or growth-retarded fetus in a horn, a mean value for the placental blood flow was calculated for that horn. Student's t test for paired or unpaired observations was used for statistical analysis. To evaluate differences in vascular reactivity between groups, relative changes of blood flows from basal values were used.

Results

Only experiments with at least one growth-retarded fetus in the ligated horn were included in the study; growth retardation was arbitrarily defined as >15% weight reduction compared with the mean fetal weight in the control horn. Maternal weights and gestational ages are given in Table I. In the growth-retarded group of the ANP series (n = 12) fetal weight was reduced by 45%, placental weight by 38%, and placental blood flow (ml/min/gm) by 58%. Corresponding reductions were seen in the control group (n = 5, Table II).

ANP infusion did not affect blood pressure, heart rate, or renal or myoendometrial blood flow (Table III). ANP administration (15 ng/kg/min) increased maternal plasma concentrations of immunoreactive ANP by 64%; plasma catecholamine concentrations did not change (Table IV). ANP infusion increased maternal placental blood flow of growth-retarded fetuses by 26% ($p < 0.01$), and blood flow to normal-sized placentas was unaltered (Fig. 1). This difference in reactivity to ANP between supplying vessels of growth-retarded and normal-sized placentas was statistically significant ($p < 0.001$). The correlation between these paired relative changes in blood flow in response to ANP was highly significant (r = 884, $p < 0.001$, n = 12); this correlation provides a statistical justification for using the paired t test. Central hemodynamics and organ blood flows remained unchanged in the control group.

Comment

Whether plasma concentrations of ANP are increased in pregnancy compared with nonpregnant controls is still a matter of controversy.[8, 9] In addition, if ANP levels are elevated in normal pregnancy the physiologic role of this increase remains unclear. In nonpregnant experimental animals ANP decreases cardiac output and plasma volume and antagonizes the renin-angiotensin system[7] in contrast to the hypervolemia, increased cardiac output, and stimulation of the renin-angiotensin system seen in normal pregnancy. Because the main stimulus for ANP release is increased tension in the right atrial wall caused by intravascular volume expansion,[7] ANP release might be enhanced because of the hypervolemic state of normal pregnancy.

In this study infusion of ANP did not affect blood flow to normal-sized placentas in contrast to findings in the anesthetized rat[10] and the chronically catheterized sheep.[11] Although these differences may be caused by interspecies variation, an alternative explanation is the use of low doses of ANP (15 ng/kg/min) in the present investigation. This should be compared with the dose of 30 μg/kg given systemically in the study of Chemtob et al.[10] and 6.25 μg/min infused locally in the uterine artery in the investigation of Reid et al.[11] Basal ANP plasma concentrations in the present study were within the range reported for arterial concentrations in laboratory animals.[7] In the conscious dog[15] plasma ANP concentrations may increase twofold to fivefold in response to physiologic stimuli such as volume loading. Thus it is highly likely that the 64% increase of the

levels of circulating ANP during ANP infusion represent concentrations within the physiologic range.

The relevance of the uterine artery ligation model in the study of placental blood flow regulation in intrauterine growth retardation has recently been addressed in some detail.[16] Fetal growth in the ligated horn is not only affected by an impairment in placental blood flow caused by the experimental manipulation but may also be influenced by, for example, the number of fetuses in the litter in general and the number of fetuses in the horn in particular. Although mean fetal weight in late gestation and mean birth weight is inversely proportional to litter size in the guinea pig, this effect cannot clearly be demonstrated before day 55 of gestation.[17] Thus fetal load characteristics are unlikely to interfere significantly in this investigation. It is also possible to estimate the effect of increasing the number of fetuses in one horn by comparing, in litters with a total of three fetuses, mean fetal weight in a control horn containing two fetuses with the mean fetal weight in a control horn with one fetus. When this was carried out with data from the present series of experiments and two similar studies from our laboratory,[16, 19] an increase in the number of fetuses from one to two in a horn decreased fetal weight by 4.5%. Thus the effect of the number of fetuses in the horn on fetal growth is likely to be only modest. In addition the mean number of fetuses in the present investigation was identical in the ligated and control horns.

To support the relevance of this experimental model of intrauterine growth retardation, there is evidence that the placenta of a small fetus produced by uterine artery ligation is qualitatively similar to the placenta of a fetus being small because of crowding effects or a small fetus occurring spontaneously as a runt. For example, the placenta that is small because of uterine artery ligation is characterized by the same degree of blood-flow reduction,[4, 18, 19] exhibits identical placental glucose and amino acid transfer characteristics,[18] and shows similar reactivity to norepinephrine[4] and prostaglandin synthesis inhibition[19] as does the placenta of the naturally occurring runt.

The striking difference in response to ANP infusion between normal-sized and growth-retarded placentas may be caused by an active up-regulation of ANP receptors in vessels supplying the small placenta. ANP receptors have been identified in non-brush border microsomal fractions from the guinea pig[20] and human

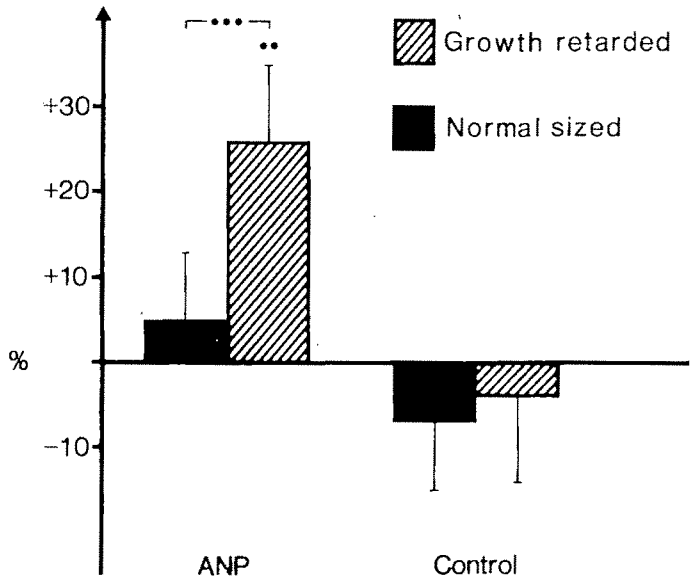

Fig. 1. Effect of ANP (15 ng/kg/min, $n = 12$) and saline infusions (control, $n = 5$) on blood flow to placentas of normal-sized and growth-retarded fetuses. *Two asterisks,* $p < 0.01$: difference between basal blood flow and blood flow during ANP infusion in the growth-retarded group; *three asterisks,* $p < 0.001$; difference in relative blood flow changes between normal-sized and growth-retarded placentas.

placenta.[21] To my knowledge no investigation has been undertaken to directly identify the presence of ANP receptors in the uteroplacental vasculature.

An alternative explanation to the current findings may be that the vessels supplying the normal-sized guinea pig placenta are maximally dilated at day 50 of gestation (0.74 gestation). The demonstration of vasodilatory capacity of the near-term ovine placental vascular bed (0.90 gestation) by local infusion of forskolin[2] suggests that this is less likely. However, infusions of forskolin or higher doses of ANP in the guinea pig would provide direct evidence.

A third possibility is that physiologic doses of ANP dilate placental vessels earlier in gestation but that this ability progressively disappears during the course of pregnancy. The responsiveness of vessels supplying the growth-retarded placenta to ANP at day 50 could be explained by a delayed development or maturation of the growth-retarded placenta and its vascular supply. Such delay has been described for different aspects of placental development in intrauterine growth retardation. For example, normal physiologic changes in uteroplacental vessels during pregnancy such as the gradual disappearance of normal muscular and elastic tissue in the vessel wall have been shown to be inadequate in idiopathic growth retardation.[22] Consequently it is possible that the vessels supplying the growth-retarded placenta contain relatively more smooth muscle compared with the placenta of normal-sized fetuses. This may be the basis for the higher ANP sensitivity of the growth-retarded placental vasculature in these experiments. In addition, blood vessels supplying the growth-retarded placenta are substantially less sensitive to circulating catecholamines as compared with the vasculature of normal-sized placenta.[19] It was suggested that this difference may be caused by a delayed sympathetic denervation to these vessels. If this holds true, the selective vasodilatory effect of ANP could result from a higher density of remaining sympathetic vasoconstrictor nerves around the growth-retarded placenta because ANP inhibits norepinephrine release from nerve endings in isolated preparations.[23] The higher sensitivity of the normal-sized placentas to circulating catecholamines[19] could explain the differential effects of ANP infusions on placental blood flow. However, the finding that plasma catecholamine concentrations were unaffected by ANP infusion precludes this possibility.

The finding that low-dose infusion of ANP markedly dilates the vessels of the growth-retarded placenta suggests that physiologic doses of the peptide may improve placental blood flow and thereby fetal outcome in intrauterine growth retardation. In the study of Chemtob et al.,[10] in which pharmacologic doses of ANP decreased blood pressure and increased placental blood flow in the anesthetized hypertensive rat, the authors suggested that ANP may have therapeutic potential in hypertensive pregnancies. However, chronic administration of high doses of ANP is likely to substantially reduce plasma volume, which is already contracted in pregnancy-induced hypertension. As a consequence, the acute beneficial effects of ANP administration may

be counteracted. With infusions of ANP in doses resulting in plasma concentrations within the physiologic range, such side effects are likely to be much less pronounced. Speculatively, a moderate volume load may be an alternative approach to increasing placental blood flow in pregnancies with intrauterine growth retardation. However, this requires the ability to respond to volume loads with an increased ANP secretion to be conserved in pregnancy. This seems to be the case in several animal species, for example, the rat.[24] In the human being, however, a volume load increased ANP levels in pregnancies complicated by pregnancy-induced hypertension[25] but not in normal pregnancies.[9] Administration of ANP in addition to a volume load may be an additional possibility. Because hemodilution per se preferentially increases blood flow to placentas of small fetuses without reducing oxygen flow in the guinea pig,[26] a volume load may also be beneficial for rheologic reasons.

In conclusion, ANP infused in physiologic doses improves blood flow to placentas of growth-retarded fetuses in the conscious guinea pig without affecting central hemodynamics, plasma catecholamines, or renal or myoendometrial perfusion. The vascular supply of placentas of normal-sized fetuses showed a different reactivity in that blood flow remained unaltered to these placentas in response to ANP. It is speculated that a low-dose infusion of ANP may have a therapeutic value in pregnancies complicated by intrauterine growth retardation.

Dr. Thomas Hedner, Department of Clinical Pharmacology, Sahlgren's University Hospital, Göteborg, Sweden, is gratefully acknowledged for invaluable advice and for carrying out the ANP assay.

The effect of preovulatory peritoneal fluid from cases of endometriosis on murine in vitro fertilization, embryo development, oviduct transport, and implantation

William G. Dodds, MD, Frederick A. Miller, MS, Chad I. Friedman, MD, Brad Lisko, BS,* Jeffrey M. Goldberg, MD, and Moon H. Kim, MD
Columbus, Ohio

OBJECTIVE: The null hypothesis of our study is that the success of in vitro and in vivo murine fertilization and embryo development is not decreased by gamete exposure to peritoneal fluid from superovulated patients with endometriosis.
STUDY DESIGN: A murine in vitro fertilization model was used to test the effects of endometriosis versus nonendometriosis peritoneal fluid at concentrations of 1%, 5%, and 10% versus an unsupplemented control. Fertilization and blastocyst formation were compared by analysis of variance. In a second experiment superovulated mice were given intraperitoneal injections of endometriosis or nonendometriosis fluid or saline solution 8 hours after human chorionic gonadotropin and then mated. Some mice were killed 3 days after coitus to assess embryo number, cleavage stage, and uterine versus tubal position by means of analysis of variance and covariance with repeated measures. Others were killed 12 days after coitus with the mean number of implantations per animal between groups compared by Student's *t* test.
RESULTS: In vitro fertilization rates decreased as peritoneal fluid concentration increased in both the endometriosis (65%, 43%, 33%) and nonendometriosis (65%, 52%, 35%) groups at 1%, 5%, and 10% peritoneal fluid concentration, respectively. Mice receiving intraperitoneal endometriosis or nonendometriosis fluid or saline solution injections showed no differences in embryo number, cleavage, uterine versus tubal position, or mean implantation number.
CONCLUSION: Peritoneal fluid from superovulated patients had no differentially negative effect when compared with the effect of nonendometriosis peritoneal fluid on murine in vitro or in vivo fertilization and embryo development, tubal embryo transport, or implantation. (Am J Obstet Gynecol 1992;166:219-24.)

Key words: Endometriosis, in vitro fertilization, murine model

The relationship between endometriosis and infertility remains to be clarified. The literature contains conflicting reports with regard to whether peritoneal fluid prostaglandin (PG) levels are elevated in patients with endometriosis.[1-4] Studies have pointed to greater peritoneal macrophage levels and in vitro sperm phagocytosis activity in endometriosis patients as a possible explanation of how endometriosis could decrease fertility.[5-9] However, other studies, including one we reported, failed to verify increased phagocytic activity.[10, 11] One recent study has reported that culture media from peritoneal fluid macrophages obtained from endometriosis patients significantly inhibited sperm penetration of zona-free hamster eggs.[12] In support of these findings, another study reported peritoneal fluid from endometriosis patients inhibited murine in vitro fertilization.[13] A problem with that study, however, was the lack of control in cycle time when peritoneal fluid specimens were collected. The large differences in cellular and hormonal composition of peritoneal fluid at different times during the menstrual cycle make this an important consideration.[11, 12]

The purpose of our study was to investigate further the effect of preovulatory endometriosis peritoneal fluid from superovulated women on mouse in vitro fertilization and subsequent embryo development. In addition, we used the murine model to evaluate the in vivo effect of endometriosis peritoneal fluid on early embryo development, tubal embryo transport, and implantation.

Material and methods

Subjects. Peritoneal fluid was collected from the anterior and posterior cul-de-sac at the time of laparoscopic oocyte retrieval in patients undergoing in vitro fertilization (IVF) or gamete intrafallopian tube transfer (GIFT) procedures. All patients were superovulated with the same human menopausal gonadotropin–follicle-stimulating hormone controlled ovarian hyperstimulation protocol. Peritoneal fluid was collected

from IVF and GIFT patients so that all specimens would be preovulatory. Blood-contaminated specimens were discarded. The peritoneal fluid was immediately filtered with a 0.22 μm filter (Millipore, Bedford, Mass.) and then snap-frozen in liquid nitrogen vapor to −140° C. It was then subsequently stored at −80° C until used. Each subject had a complete evaluation of the peritoneal cavity for the presence and extent of endometriosis. Ten consecutive endometriosis and 10 nonendometriosis specimens were collected for study. All patients underwent staging according to the American Fertility Society revised classification system.[14] Five of the endometriosis patients had prior laparoscopic diagnosis of endometriosis. There had been no medical or surgical treatment for endometriosis in any of these five patients for >6 months before this study. The other five patients were newly diagnosed as having endometriosis at the time of IVF or GIFT laparoscopy. The nonendometriosis control peritoneal fluid specimens were obtained from the tubal and male factor infertility patients undergoing IVF and GIFT, respectively. All of the women in both the endometriosis and nonendometriosis groups had negative indirect serum Immunobead sperm antibody studies. All specimens were coded by number to allow blinding of the laboratory technicians performing the various assays. A total of 10 endometriosis and 10 nonendometriosis peritoneal fluid specimens were analyzed for each assay described in the subsequent sections.

Mouse in vitro fertilization assay. Juvenile CB_6F_1 female mice and sexually mature CB_6F_1 male mice (Charles River, Wilmington, Mass.) were the sources of the oocytes and sperm. This strain has consistently provided in vitro fertilization results of 70%. Ovulation was induced with intraperitoneal pregnant mare serum gonadotropin followed 48 hours later by 7.5 IU human chorionic gonadotropin (hCG) also given intraperitoneally. The females were killed by cervical dislocation 13 to 16 hours after hCG. The oviduct was excised and placed in 2.5 ml of Whitten's fertilization media containing 30 mg/ml crystalline bovine serum albumin. A sterile needle was used to incise the oviduct and liberate the oocyte clumps. The oocyte clumps were then pooled and placed into 0.5 ml drops of Whitten's fertilization media and overlaid with mineral oil. Males were killed by cervical dislocation 1 hour before females were killed. Both cauda epididymides were removed and placed into 0.9 ml Whitten's fertilization media. Sperm was extracted with jeweler's forceps by applying gentle pressure on the cauda epididymis. The sperm suspension was examined at 10 minutes for the presence of whirlpool formation, and a concentration was determined with a Makler chamber. Ninety minutes after sperm collection, the oocytes were inseminated with 100 μl of sperm suspension by means of a micropipette. Fertilization media were supplemented in a blinded fashion with peritoneal fluid from nonendometriosis and endometriosis patients. An unsupplemented Whitten's media group served as another control group. Peritoneal fluid concentrations of 1%, 5%, and 10% were evaluated. Endometriosis and nonendometriosis peritoneal fluid and Whitten's control specimens were run in parallel fashion for each concentration with a minimum of 100 oocytes evaluated for each test specimen. After 6 hours in Whitten's fertilization media, all oocytes were transferred to Whitten's growth media containing 3 mg/ml bovine serum albumin. Oocytes from the endometriosis and nonendometriosis 1%, 5%, and 10% supplemented fertilization media were transferred to appropriately matched 1%, 5%, or 10% endometriosis or nonendometriosis peritoneal fluid–supplemented Whitten's growth media. Fertilization and embryo culture were carried out in a modular incubator chamber (Billups-Rothenberg, Del Mar, Calif.) in a trigas mixture of 90% nitrous oxide, 5.5% oxygen, 4.5% carbon dioxide. Fertilization defined at the two-cell cleavage stage was assessed at 24 hours. Two-cell embryos from test and control groups were then transferred to fresh, unsupplemented Whitten's growth media. Embryos were cultured for 96 hours after insemination and blastocyst transformation rate was scored under phase contrast microscopy.

In vivo mouse assay. CD-1 female mice (Charles River) underwent ovulation induction in a fashion similar to that performed in the in vitro fertilization mouse assay with 7.5 IU pregnant mare serum gonadotropin given intraperitoneally followed by 7.5 IU hCG intraperitoneally 48 hours later. Eight hours after hCG, which represented approximately 2 to 3 hours before ovulation, the female mice were given an intraperitoneal injection of 0.2 ml of peritoneal fluid from either the endometriosis or nonendometriosis study specimens. Six mice were tested with each patient's peritoneal fluid specimen. A control group of six mice given an intraperitoneal injection of 0.2 ml of normal saline solution also underwent follow-up. Each female was placed in an individual mating cage with a CD-1 male. Vaginal plug formation was evaluated at 24 hours. A minimum of three successfully mated animals for each peritoneal fluid tested and each control group was required for evaluation. At 72 hours the females were killed by cervical dislocation. The fallopian tubes and uterus were flushed separately, and the number of embryos and stage of development for both tube and uterus were scored.

In vivo mouse implantation assay. Ovulation induction and mating of CD-1 female and male mice was carried out as in the preceding in vivo mouse assay section. Again, 0.2 ml intraperitoneal injections of endometriosis and nonendometriosis peritoneal fluid were tested along with a 0.2 ml intraperitoneal normal saline solution control group. Again intraperitoneal in-

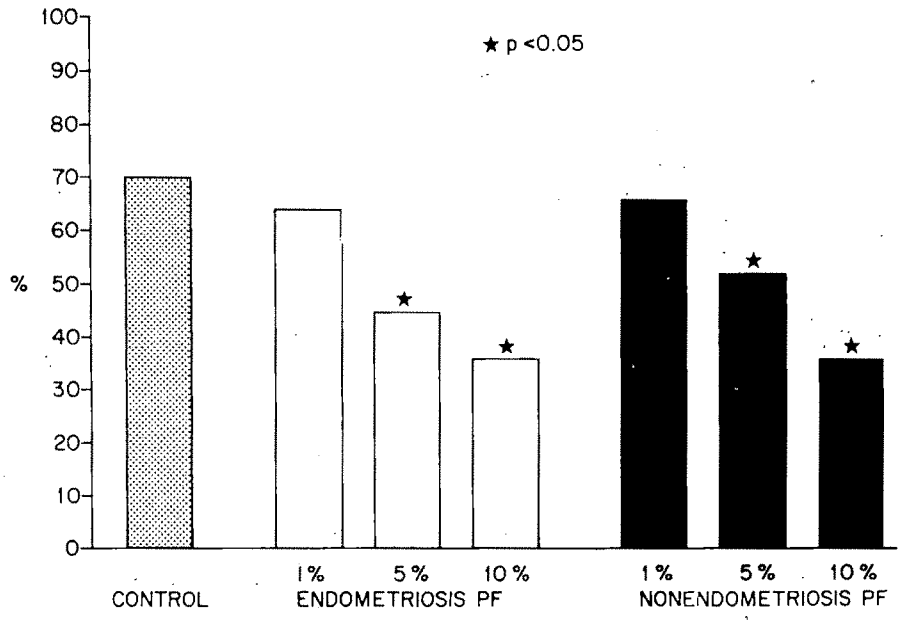

Fig. 1. Percent of oocytes fertilized in vitro is shown for nonsupplemented control and peritoneal fluid–supplemented endometriosis and nonendometriosis groups. There was no significant difference in oocyte fertilization between control, 1% endometriosis, and 1% nonendometriosis groups. There was a significant decrease in oocyte fertilization in both endometriosis and nonendometriosis peritoneal fluid groups as percent of supplemented peritoneal fluid was increased.

jections were given 8 hours after hCG. Ten animals for each patient specimen were tested in parallel runs. A minimum of four successfully mated animals in each test and control group was required for evaluation. Females were killed 12 days after coitus and number of embryos was scored for each group.

Data analysis. In vitro fertilization and blastocyst transformation rates were analyzed by analysis of variance. Evaluation of in vivo embryo development and tubal versus uterine position between groups was by analysis of variance and covariance with repeated measures. Mean number of gestations per animal between groups in the in vivo mouse implantation assay was compared by Student *t* test.

Results

A comparison of the mean patient age (32 ± 5.2 vs 33 ± 5.7 years) and time of hCG and estradiol administration (1442 ± 432 vs 1518 ± 506 days) between the endometriosis and nonendometriosis groups revealed no significant differences. The endometriosis patients consisted of two patients with stage II, six with stage III, and two with stage IV disease. All but one had endometriosis involving at least one ovary.

As depicted in Fig. 1, there was a progressive decrease in the in vitro fertilization rates as the peritoneal fluid concentration increased in both the endometriosis and nonendometriosis peritoneal fluid groups. There was no difference, however, in fertilization rates between the two groups when the rates were compared at similar concentrations of peritoneal fluid. In addition, there was no impairment of subsequent two-cell embryo development in the peritoneal fluid groups compared with the unsupplemented media control group. Blastocyst transformation and embryo degeneration rates were equal among the three groups.

Table I summarizes the results of embryo development and tubal transport from the second group of experiments in which periovulatory mice were given an intraperitoneal injection of endometriosis or nonendometriosis peritoneal fluid or saline solution. The mean number of blastocysts, morula, and two- to eight-cell, one-cell, and degenerated embryos and their distribution in the oviducts and uterus at 3 days after coitus were similar in all three groups. The mating and conception rates (not depicted in Table I) were also similar in all three groups. The 12-day postcoitus implantation results of those mice given periovulatory intraperitoneal injections of endometriosis, nonendometriosis versus saline solution control are summarized in Table II. Again, there was no difference in the mean number of gestational sacs among the groups.

Comment

The role of endometriosis in causing infertility is clear when there is significant adhesive disease involving the fallopian tubes or when there is extensive destruction of the ovaries by endometrioma. However, in patients with mild or moderate endometriosis without pelvic adhesive disease the relationship to infertility is

unclear. Most recent investigations of endometriosis have focused on local peritoneal factors including peritoneal fluid prostaglandin and leukotriene levels, activity and concentration of peritoneal fluid macrophages, and peritoneal fluid macrophage secretory products. At present, no consensus exists as to whether peritoneal fluid prostaglandins or leukotriene levels are increased in patients with endometriosis because the published studies have yielded conflicting results.[1, 3, 15] A role for pelvic macrophages as potential mediators of infertility in patients with endometriosis has also been studied extensively with equally conflicting results reported.[8-12]

Other researchers have focused on local immunologic changes in patients with endometriosis as a potential mechanism that interferes with fertility. Interleukin-1 and interleukin-2, which are secretory products of activated macrophages and activated T cells, respectively, have been the most thoroughly studied. A study by Hill et al.[16] found that only very high concentrations of interleukin-1 inhibited the in vitro development of mouse embryos from the two-cell to blastocyst stage.[16] In a more recent investigation, Schneider et al.[17] reported that purified recombinant interleukin-1 and interleukin-2 had no effect on in vitro mouse embryo development from the four-cell to blastocyst stage or on early stages of implantation as measured in vitro by attachment and outgrowth of blastocysts to fibronectin-coated dishes.

Schneider et al. also cocultured mouse embryos with activated peritoneal macrophages from patients with endometriosis and found no effect on embryogenesis. These results concurred with our prior finding of no difference in interleukin-1 levels between infertile patients with and without endometriosis.[10] However, it remained possible that interleukin-1, interleukin-2, another cytokine, or an as yet unidentified labile soluble factor in peritoneal fluid could affect ovulation, fertilization, or tubal embryo transport and implantation. In the current study we attempted to address that issue by evaluating periovulatory peritoneal fluid from superovulated infertile endometriosis patients. We felt it important to snap-freeze the peritoneal fluid to −140° C and then store it at −80° C until it was used in our studies in an effort to preserve potentially important labile factors. Our finding of a decrease of in vitro fertilization rates in mice as the concentrations of peritoneal fluid supplemented to the fertilization media were increased was similar to that reported by Sueldo et al.[13] One explanation for the decrease in fertilization rate as the peritoneal fluid concentration increased may be that it is from superovulated patients. As noted in Fig. 1, this decrease was equal in both the endometriosis and nonendometriosis groups. In contradistinction to Sueldo et al., we found no difference in murine in vitro fertilization rates between the endometriosis and nonendometriosis peritoneal fluid groups. Our results are in agreement with the study findings of Halme et al.,[18] who found that peritoneal fluid from endometriosis patients compared with peritoneal fluid from nonendometriosis patients did not adversely affect spermatozoa penetration of zona-free hamster eggs. One criticism of the current study is that if peritoneal fluid from superovulated patients is gamete toxic, then it is possible that subtle adverse effects of endometriosis may not have been detected.

We further cultured the in vitro fertilized embryo to see if there was any subtle effect on the oocyte or early embryo that may be manifested as a decrease in its blastocyst transformation potential. No difference was found between the endometriosis peritoneal fluid, nonendometriosis peritoneal fluid, and unsupplemented control groups. Gametes were only exposed for the first

24 hours of culture of peritoneal fluid supplement to allow us to focus on effects of endometriosis peritoneal fluid on fertilization. We have previously shown that endometriosis peritoneal fluid did not affect in vitro two-cell to blastocyst transformation.[10]

A recent study by Hahn et al.[19] in a rabbit model in which endometriosis was surgically induced found results similar to our in vitro murine endometriosis peritoneal fluid model with respect to the effect of endometriosis on ovulation, fertilization, and early embryo development. In their experiment animals were mated and killed 1, 4, 8, or 14 days after insemination. They flushed the uterus and tubes from animals killed on both day 1 and day 4 after insemination and found results similar to ours with no difference in the number of corpora lutea or fertilized ova between animals with endometriosis and the nonendometriosis controls. However, in those rabbits killed on days 8 and 14, they found a significant decrease in the number of implantation sites. Hahn et al. also collected peritoneal fluid from rabbits with endometriosis and injected it intraperitoneally to a group of normal female rabbits 24 hours before insemination. They reported that this group also had a significant decrease in the number of successful implantations. One possible explanation for this is that the mouse has a bursa connecting its distal tube and ovary together. It may be that this bursa effectively blocks important factors in the intraperitoneally injected endometriosis peritoneal fluid. It could also be a weakness in our in vivo model study design in giving the intraperitoneal fluid only 3 hours before anticipated ovulation. However, the reason we chose to give our intraperitoneal fluid in this manner was to obtain a high concentration of the peritoneal fluid at the time of ovulation to primarily test its effect on fertilization. In testing the pregnant mare serum gonadotropin–stimulated CD-1 female mouse, we had found the periovulatory peritoneal fluid volume to be 0.1 to 0.2 ml; therefore a 0.2 ml intraperitoneal fluid injection represented a substantial test dose.

The lack of an in vivo effect of endometriosis peritoneal fluid in the mouse certainly does not necessarily equate with the effect endometriosis may have in the human. However, in a recent review of endometriosis and human IVF, Oehninger et al.[20] reported that regardless of stage of endometriosis there was no difference in rates of fertilization, embryo cleavage, or pregnancy per embryo transfer between endometriosis and nonendometriosis patients. However, that study did report a higher miscarriage rate and lower ongoing pregnancy rate in those patients with stage III or IV disease. Although that is a retrospective review, it suggests that in more advanced endometriosis cases an as yet undefined factor(s) may adversely affect either embryo quality or the uterine environment. If there are oocyte- or embryo-inhibiting factor(s) produced in patients with advanced endometriosis, their suppressive effects may be manifested more in patients undergoing GIFT because fertilization and early development are in vivo. Further clinical study of both IVF and GIFT success in patients with endometriosis is needed.

In conclusion, this study demonstrated that peritoneal fluid from superovulated endometriosis patients had no differentially negative effect on mouse in vitro fertilization, embryo development, tubal embryo transport, or implantation. Potential subtle effects of endometriosis on embryo development and implantation will require further investigation.

Attenuation of the vasoconstrictor effects of thromboxane and endothelin by nitric oxide in the human fetal-placental circulation

Leslie Myatt, PhD,[a, b, c, d] Anthony S. Brewer, BS,[b] Gretchen Langdon, BA,[b] and Diane E. Brockman, MS[b]

Cincinnati, Ohio

OBJECTIVE: We hypothesized that the endothelial-derived relaxing factor nitric oxide may contribute to low resting vascular tone and may attenuate vasoconstrictor action in the human fetal-placental circulation.
STUDY DESIGN: Isolated human placental cotyledons were dually perfused in vitro, and the effects of N-monomethyl-L-arginine and N-nitro-L-arginine (3×10^{-4} mol/L), which are nonmetabolizable analogs of L-arginine, the substrate for nitric oxide synthase, on resting perfusion pressure and on the fetal-placental circulation preconstricted with U46619 (10^{-8} mol/L) or endothelin-1 (10^{-8} mol/L) were established. Responses before and after inhibition were compared by paired *t* test. The effects of glyceryl trinitrate (10^{-6} mol/L), acetylcholine (10^{-4} mol/L), the calcium ionophore A23187 (10^{-6} mol/L), and histamine (10^{-8} to 10^{-4} mol/L) were also determined in the preconstricted fetal-placental circulation.
RESULTS: Both N-monomethyl-L-arginine and N-nitro-L-arginine (3×10^{-4} mol/L) increased resting perfusion pressure ($p < 0.06$), and N-nitro-L-arginine promptly and significantly increased perfusion pressure in the fetal-placental circulation preconstricted with U46619 ($p < 0.0004$) or endothelin-1 ($p < 0.06$). Nitric oxide generated by addition of glyceryl trinitrate (10^{-6} mol/L) attenuated the vasoconstrictor effects of U46619 ($p < 0.026$) or endothelin-1 ($p < 0.01$). Neither acetylcholine nor the calcium ionophore A23187 had an effect on the fetal-placental circulation, whereas bradykinin further increased perfusion pressure. Histamine only relaxed the preconstricted preparations at concentrations (10^{-6} to 10^{-4} mol/L) above those shown to release nitric oxide in other systems.
CONCLUSION: The stimulus to nitric oxide generation in the fetal-placental circulation may be hydrodynamic. Nitric oxide appears to contribute to maintenance of basal vascular tone and to attenuate the actions of vasoconstrictors in this circulation. (Am J Obstet Gynecol 1992;166:224-30.)

Currently a great wealth of literature is being generated concerning the production and mechanism of action of endothelial-derived vasoactive agents that may act in an autocrine or paracrine manner to regulate vascular tone. These agents include endothelial-derived relaxing factors[1] such as nitric oxide[2] and endothelial-derived constricting factor or endothelin.[3] In the absence of nerves in the umbilical and placental vessels, blood flow in the human fetal-placental circulation

must be regulated by humoral agents or autocrine-paracrine mechanisms. We have previously presented indirect evidence[4] that the vasodilator nitric oxide may be produced by the human fetal-placental circulation in vitro and may contribute to maintenance of basal vascular tone. We further demonstrated that agents which generated nitric oxide in vitro were able to vasodilate the human fetal-placental circulation preconstricted with the thromboxane mimetic U46619. Nitric oxide is synthesized by a calcium, calmodulin, and nicotinamide adenine dinucleotide phosphate–requiring enzyme, nitric oxide synthetase,[5] which has been found in endothelial cells[6] and at several neural locations[7] and which forms nitric oxide from the guanidino nitrogen of the amino acid L-arginine. This discovery has led to the synthesis of several competitive inhibitors of nitric oxide formation,[8] which can be used to provide more specific data on the synthesis and action of nitric oxide. The human fetal-placental circulation can be constricted in a concentration-dependent manner by both thromboxane mimetics[9] and by endothelin-1,[10] a peptide that produces long-acting vasoconstriction. Nitric oxide may be released by the fetal-placental circulation to attenuate the actions of vasoconstrictors in a manner similar to that we have previously described for the vasodilator prostacyclin.[9] We have used two inhibitors of nitric oxide synthesis to further define the action of nitric oxide in the human fetal-placental circulation, particularly the attenuation of vasoconstrictor action, and we have also begun to investigate the mechanisms that stimulate release of nitric oxide in the fetal-placental circulation in vitro.

Material and methods

Placentas were collected immediately after normal vaginal delivery or elective cesarean section and transported to the perfusion laboratory in the labor and delivery area. In this and previous studies,[4, 9, 11] we found no difference in vascular reactivity between tissues obtained at cesarean section and those taken at vaginal delivery. A suitable third- or fourth-order chorionic artery and corresponding vein of an intact cotyledon were cannulated as previously described[11] at a point immediately before passage of the vessels through the chorionic plate. The maternal intervillous space was cannulated with two butterfly needles inserted through remnants of the spiral arteries in the basal plate. The effluent from the intervillous space was collected by gravity into a Plexiglas cone, over which the cotyledon was placed, maternal surface downward. Perfusion medium, except where stated, was tissue culture medium 199 containing 5% polyvinylpyrrolidone 40 and 0.1% bovine serum albumin as oncotic agents and with 20 IU/ml heparin and 48 μg/ml gentamicin added. Medium was pH 7.4 with bicarbonate and gassed with 95% oxygen–5% carbon dioxide at 37° C. Flow rates were 4 ml/min for fetal tissue and 10 ml/min for maternal tissue except where stated. Lateral pressure was measured in fetal and maternal inflow lines adjacent to the point of cannulation. Data on pressure and inflow and outflow P_{O_2} were sampled every second and stored on an IBM PS2 system with Asystant Plus software (Asyst Technologies, Rochester, N.Y.).

The effect of agonists that stimulate endothelium-derived relaxing factor formation in other vascular systems was investigated. The fetal-placental circulation was preconstricted by addition of the thromboxane mimetic U46619 (10^{-8} mol/L) to the fetal perfusate and by constant perfusion with this solution. When the fetal-placental circulation had constricted and perfusion pressure had equilibrated, a 2 ml bolus of acetylcholine (10^{-4} mol/L), the calcium ionophore A23187 (10^{-6} mol/L), or bradykinin (10^{-6} mol/L) was infused into the fetal-placental circulation and changes in perfusion pressure were recorded. Similar experiments were performed with infusion of boluses of increasing concentrations of histamine (10^{-8} to 10^{-4} mol/L) into the preconstricted fetal-placental circulation and recording of changes in perfusion pressure.

The effects of two competitive inhibitors of nitric oxide synthetase were next investigated. The perfusion medium normally used (medium 199) contains 3×10^{-4} mol/L L-arginine, the substrate for nitric oxide synthesis; therefore the medium for these experiments was changed to Hanks' buffered saline solution, pH 7.4, containing oncotic agents, heparin, and antibiotics as before and gassed with 95% oxygen–5% carbon dioxide. After establishment of the perfusion, a 30-minute period of equilibration was allowed for washout of endogenous L-arginine before addition of either N^G-monomethyl-L-arginine (NMLA, 3×10^{-4} mol/L) or N^G-nitro-L-arginine (NNLA, 10^{-3} mol/L) to both the maternal and fetal perfusates. Changes in perfusion pressure were recorded throughout. In a separate series of experiments, U46619 (10^{-8} mol/L, constant infusion) or endothelin-1 (10^{-8} mol/L, 2 ml bolus infusion) was added to the fetal perfusate after the washout period to constrict the fetal-placental circulation. When perfusion pressure had reequilibrated at the increased level, NNLA (10^{-3} mol/L) was added to both maternal and fetal perfusates, and perfusion was continued with changes in perfusion pressure being recorded.

All experiments were repeated in at least four separate placentas. U46619 was kept as a 10^{-3} mol/L stock in ethanol at −20° C and diluted before use. Endothelin-1 was stored at 10^{-5} mol/L in 0.5 mol/L acetic acid at −70° C. NMLA and NNLA were made fresh as 10^{-3} mol/L solutions before use. The vasodilator response to histamine was expressed as percent relaxation from

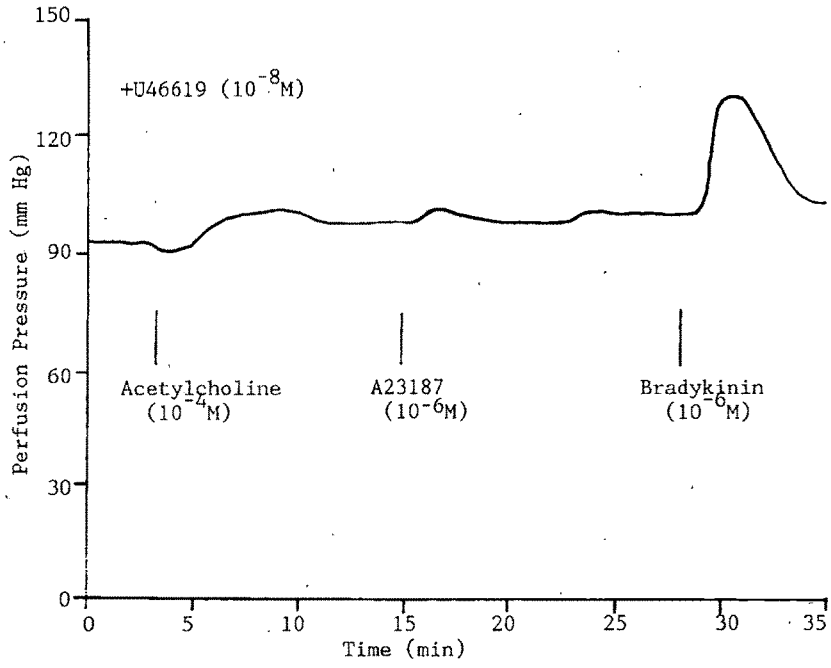

Fig. 1. Representative experiment of effect of acetylcholine (10^{-4} mol/L), ionophore A23187 (10^{-6} mol/L), or bradykinin (10^{-6} mol/L) on perfusion pressure in fetal-placental circulation preconstricted with U46619 (10^{-8} mol/L).

the resting perfusion pressure in each placenta. Vasoconstrictor responses to NMLA and NNLA were expressed as percent change from resting perfusion pressure in each placenta. Changes in perfusion pressure were analyzed by analysis of variance or by paired *t* test where appropriate. All procedures were approved by the University of Cincinnati College of Medicine Institutional Review Board.

Results

Acetylcholine (10^{-4} mol/L) and the calcium ionophore A23187 (10^{-6} mol/L) had no significant effect on perfusion pressure (increases in pressure of 1.3 ± 0.4 and 5.1 ± 0.9 mm Hg, respectively) in the preconstricted human fetal-placental circulation whereas bradykinin (10^{-6} mol/L) consistently gave further vasoconstriction (mean ± SEM 19.4 ± 8.1 mm Hg, $n = 5$) in addition to that already caused by the U46619 (Fig. 1). However, histamine was able to significantly attenuate ($p < 0.0001$, analysis of variance) U46619-induced vasoconstriction in a concentration-dependent manner from 10^{-6} to 10^{-4} mol/L (Fig. 2).

No difference in resting perfusion pressure was seen regardless of whether medium 199 or Hanks' buffered saline solution was used as perfusion medium. Addition of either NMLA (3×10^{-4} mol/L) or the more potent inhibitor of nitric oxide synthesis,[12] NNLA (10^{-3} mol/L), to perfusion medium increased resting perfusion pressure; however, the increase did not reach statistical significance ($p < 0.06$, Fig. 3). When the fetal-placental circulation was preconstricted with U46619 (10^{-8} mol/L), addition of NNLA (10^{-3} mol/L) produced a prompt further significant increase ($p < 0.027$) in perfusion pressure (Fig. 4, Table I). The increase in perfusion pressure reached a maximum after 15 minutes and then started to decline and returned with time to a pressure not significantly different from that before addition of NNLA (Fig. 4). The difference in perfusion pressure between the maximum obtained on addition of NNLA and that on return to baseline was significant ($p < 0.027$, data not shown).

Endothelin-1 (10^{-8} mol/L) given as a bolus significantly increased perfusion pressure ($p < 0.004$, Table I). Addition of NNLA (10^{-3} mol/L) to perfusion medium then increased perfusion pressure further ($p < 0.06$). In separate experiments glyceryl trinitrate (10^{-6} mol/L) significantly reduced ($p < 0.01$) perfusion pressure in the fetal-placental circulation preconstricted with endothelin-1 (Table II) in agreement with the reduction in perfusion pressure by glyceryl trinitrate ($p < 0.026$) in the fetal-placental circulation preconstricted with U46619.

Comment

We have previously demonstrated[4] that agents which generate nitric oxide (glyceryl trinitrate and S-nitroso-

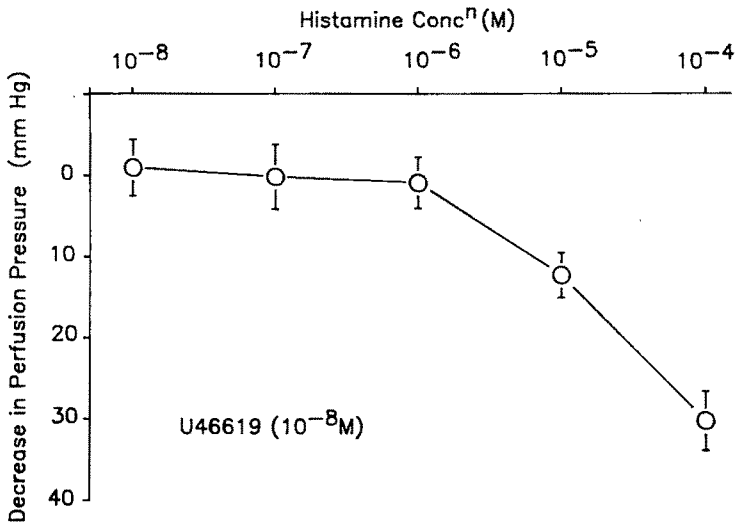

Fig. 2. Effect of histamine on preconstricted fetal-placental cotyledon. Fetal-placental vasculature of isolated cotyledons was preconstricted with continuous infusion of U46619 (10^{-8} mol/L) and then increasing concentrations of histamine (10^{-8} to 10^{-4} mol/L) were infused as a 2 ml bolus. Change in perfusion pressure was expressed as percent decrease from resting pressure (mean ± SEM, $n = 5$ experiments). One-way analysis of variance showed significant decrease in perfusion pressure with increasing concentration of histamine ($p < 0.0001$). Decrease in perfusion pressure at 10^{-5} and 10^{-4} mol/L histamine was significantly different from that at 10^{-6} mol/L histamine ($p < 0.05$, Student–Newman-Keuls).

N-acetyl-penicillamine) were able to relax the human fetal-placental vasculature preconstricted in vitro with a thromboxane mimetic. By using methylene blue, an inhibitor of endogenous nitric oxide action, we further provided evidence for a role of nitric oxide in maintenance of basal vascular tone in this preparation and demonstrated that inhibition of the action of nitric oxide on guanylate cyclase gave small but significant increases in resting perfusion pressure. Using the derivatives of L-arginine (NNLA and NMLA), which are competitive inhibitors of nitric oxide synthetase, we are currently able to demonstrate further increases in perfusion pressure in the preconstricted fetal-placental circulation by addition of these compounds and presumptive inhibition of nitric oxide formation. Although addition of these inhibitors to perfusion medium did increase resting perfusion pressure, the increase did not quite reach significance ($p < 0.06$). Interestingly, this contrasts with our previous finding[4] that methylene blue, which inhibits the action of nitric oxide, significantly increased perfusion pressure, but this lack of significant effect may be due to the continuing presence of endogenous L-arginine in the preparation, which is forming nitric oxide and competing with the inhibitor in spite of the use of Hanks' buffered saline solution as perfusate. The concentration of L-arginine in placental tissues is 3×10^{-4} mol/L, so it is possible that complete depletion of endogenous substrate for nitric oxide synthetase cannot be easily achieved by perfusion with Hanks' buffered saline solution. Gude et al.[15] did report that addition of NNLA, methylene blue, or oxyhemoglobin was able to significantly increase resting perfusion pressure when Krebs solution was used as perfusate. The reasons for the disparity with our findings, other than the different experimental technique, are not readily apparent from their report.

The effect of the competitive inhibitor NNLA in the preconstricted circulation was rapid in onset, reached a plateau after about 15 minutes, but then apparently was lost as perfusion pressure returned to the level seen before addition of the analog. In other in vitro systems[14] the effect of such competitive inhibitors is purportedly only reversible on addition of L-arginine, the substrate for nitric oxide synthetase. A primary function of the placenta is the active transport of amino acids from mother to fetus, and the placenta contains a high concentration of L-arginine; therefore this endogenous pool may be competing with the inhibitor as we have described. To minimize this effect, we replaced our normal perfusion medium (medium 199), which itself contains L-arginine, with Hanks' buffered saline solution and preperfused the preparation for 30 minutes to wash out amino acids. However, the lack of persistent increase in perfusion pressure on addition of the inhibitor suggests either that there is still either sufficient endogenous L-arginine present, that release of another

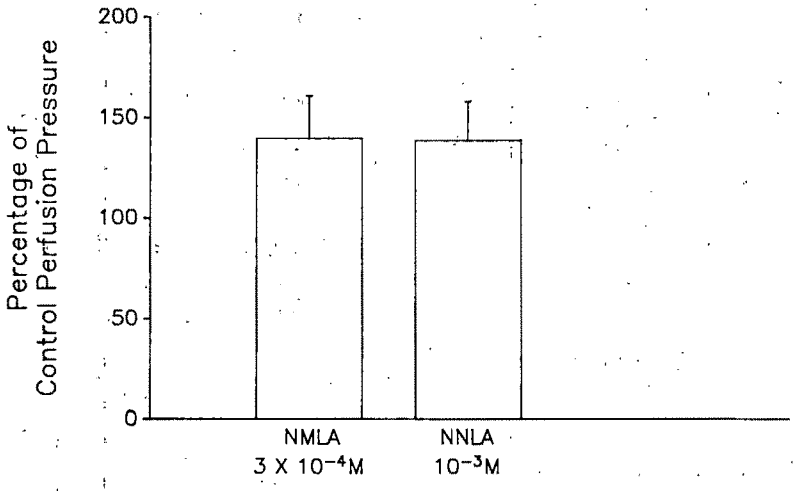

Fig. 3. Effect of competitive inhibitors of nitric oxide synthesis on resting perfusion pressure in fetal-placental circulation. Effect of bolus infusion of either NMLA (3×10^{-4} mol/L) or NNLA (10^{-3} mol/L) on resting perfusion pressure in fetal-placental vasculature. Resulting perfusion pressure was expressed as percent of resting pressure (mean ± SEM, $n = 5$ experiments).

compensatory vasodilator occurs as pressure increases, or that protein breakdown may be occurring in the placenta perfused with Hanks' buffered saline solution to release amino acids (L-arginine) that could be converted to nitric oxide.

In an attempt to establish the stimulus to release of nitric oxide in the perfused cotyledon, we studied the effect of vasodilator agonists that are normally thought to act in other systems via release of nitric oxide. Neither acetylcholine nor the calcium ionophore A23187 was able to vasodilate the preconstricted cotyledon. The absence of effect of acetylcholine on the perfused cotyledon and on the release of endothelium-derived relaxing factor from umbilical vessels has been previously reported,[15,16] and Griggs and McLaughlin[17] showed that A23187 could not relax preconstricted human chorionic plate arteries. In agreement with other reports,[18] we found that bradykinin was a vasoconstrictor in this preparation and indeed further increased perfusion pressure. To demonstrate vasodilation, we needed higher concentrations of histamine (10^{-5} to 10^{-4} mol/L) than those shown to be effective in other systems,[19] including release of endothelium-derived relaxing factor from umbilical vein.[16] However, this finding is in contrast to that of Griggs and McLaughlin,[17] who showed 10^{-6} mol/L histamine to further constrict preconstricted chorionic plate arteries. The stimulus to nitric oxide release in the fetal-placental vasculature is therefore more likely to be pressure or flow-shear stress in the vascular bed. Our previous report[4] has demonstrated an apparent flow-induced release of nitric oxide.

Inhibition of nitric oxide formation by addition of nonmetabolizable analogs of L-arginine, although having no significant effect in our hands on resting perfusion pressure, further increased the vasoconstriction induced by both U46619 and endothelin-1. Although the effect on endothelin-1–induced vasoconstriction failed to reach significance ($p < 0.06$), nitric oxide generated by addition of glyceryl trinitrate was able to sig-

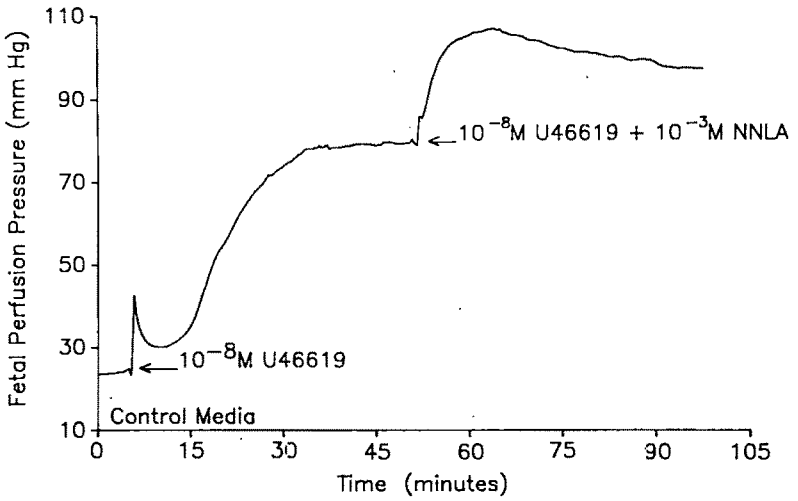

Fig. 4. Effect of N^G-nitro-L-arginine on perfusion in preconstricted fetal-placental vasculature. Representative tracing is shown of effect of infusion of NNLA (10^{-3} mol/L) on perfusion pressure in fetal-placental vasculature preconstricted by constant infusion of U46619 (10^{-8} mol/L).

Table II. Effect of generation of nitric oxide on U46619 and endothelin-induced vasoconstriction

	No.	*Perfusion pressure (mm Hg)*		
		Control	*With agonist*	*With glyceryl trinitrate (10^{-5} mol/L)*
U46619 (10^{-8} mol/L)	4	22.6 ± 2.6	116.5 ± 14.0*	77.6 ± 9.1†
Endothelin-1 (10^{-8} mol/L)	4	25.8 ± 2.6	77.9 ± 9.2‡	59.0 ± 8.7§

Values are mean ± SEM. Significance determined by paired *t* test.
*Significant increase from control, $p < 0.0002$.
†Significant difference from agonist alone, $p < 0.026$.
‡Significant increase from control, $p < 0.01$.
§Significant difference from agonist alone, $p < 0.01$.

nificantly relax the fetal-placental circulation preconstricted with endothelin-1, in agreement with our previous findings against U46619-induced vasoconstriction.[4] Therefore nitric oxide does appear to be formed to act as a compensatory vasodilator to attenuate the actions of both vasoconstrictors. Interestingly, there appears to be a heterogeneity of sensitivity of responsiveness to endothelin-1 between human arteries and veins, with greater sensitivity in veins and within the venous system.[20] In arteries, nitric oxide inhibited endothelin-1–induced vasoconstriction but was less effective in veins, although it appeared to be effective against norepinephrine-induced vasoconstricted veins. The relative production and effectiveness of nitric oxide between arteries and veins are as yet unknown.

In summary, by using competitive inhibitors, we have obtained evidence that the formation of nitric oxide contributes to the maintenance of resting vascular tone and attenuates the action of vasoconstrictor agents in the human fetal-placental circulation. The stimulus to formation of this nitric oxide may be physical or hydrodynamic or may be a specific stimulus by the vasoconstrictor agent itself. However, it does occur in response to vasoconstriction by both the thromboxane mimetic U46619 and by endothelin-1.

We thank the labor and delivery staffs of University Hospital and the Good Samaritan Hospital, Cincinnati, Ohio, for their efforts in providing placental tissues.

Influence of terbutaline on ovine uterine response to prostaglandin E_2 challenge

Deborah L. Reid, PhD, Susan R. Davidson, MD, Terrance M. Phernetton, BS, and John H.G. Rankin, PhD

Madison, Wisconsin

OBJECTIVE: Our purpose was to test the effects of terbutaline on uterine electric and contractile responses to prostaglandin E_2.

STUDY DESIGN: In five late-gestation ewes, prostaglandin E_2 (22.9 ± 2.3 μg/min for 3 minutes) was given twice at 30-minute intervals during control. Terbutaline sulfate (2 μg/min) was then infused for 30 minutes. Prostaglandin E_2 challenge was repeated 10 minutes after the onset of terbutaline infusion and thereafter at 30-minute intervals. Two-way analysis of variance for repeated measures revealed a significant main effect for time ($p \leq 0.0001$) and between time and response ($p \leq 0.05$).

RESULTS: Both electric ($p \leq 0.0001$) and intrauterine pressure ($p \leq 0.0001$) responses were suppressed during terbutaline. The influence on intrauterine pressure persisted 10 minutes after terbutaline ($p \leq 0.01$) while the electric response was not different from control.

CONCLUSIONS: Terbutaline initially diminishes both uterine contractile and electric activity, but electric recovery precedes contractile recovery. (Am J Obstet Gynecol 1992;166:231-5.)

Key words: Tocolysis, terbutaline, sheep, excitation-contraction coupling

Terbutaline, a short-acting β_2 sympathomimetic, is a commonly used agent for prevention of preterm labor.[1-3] The tocolytic power of β_2-adrenergic-receptor agonists is mediated by activation of adenyl cyclase and increases in myometrial intracellular cyclic adenosine monophosphate. The rise in cyclic adenosine monophosphate is responsible for decreased intracellular concentration of calcium and decreased activity of myosin light-chain kinase at a given calcium concentration.[4, 5, 6] The β_1-and β_2-adrenergic-receptor agonist isoprenaline has been reported to weaken the coupling between contraction and excitation in smooth muscles.[7] We have reported a similar action produced by systemic infusion of forskolin, a compound that also stimulates increased intracellular cyclic adenosine monophosphate.[8]

We designed an experiment to determine the effects of terbutaline tocolysis on the electric and contractile activities of the pregnant ovine myometrium. The uterine electromyogram and intrauterine pressure responses to repeated prostaglandin E_2 challenges were measured to determine the time course of the action of terbutaline infusion on myometrial excitation and contraction in response to prostaglandin E_2 challenge.

Material and methods

All guidelines for the care and use of animals as approved by the University of Wisconsin were followed throughout the course of these experiments. Operations were performed on five time-bred pregnant ewes on day 125 ± 1 of gestation. Food and water were withheld from each ewe for 24 hours before surgery. Ketamine (10 mg/kg) and atropine (10 μg/kg) were administered intramuscularly to induce anesthesia and to reduce tracheal secretions, respectively. An anesthetized state was maintained throughout surgery by intravenous ketamine that was infused through a jugular vein catheter and supplemented when necessary by pentobarbital sodium. Surgical protocol followed our standard procedure.[9] A fetal hind limb was accessed through a midline laparotomy and hysterotomy. Vascular catheters were inserted into an artery and vein, and the tips were advanced to positions in the abdominal aorta and inferior vena cava, respectively. A third catheter with side holes was anchored to the incision site to monitor intrauterine pressure. The uterine incision was then repaired. Three Cooner (Cooner Sales Co., Chatsworth, Calif.) electrode wires were tied into the myometrium to acquire the uterine electromyogram signal. Catheters were inserted bilaterally into the maternal hind limb arteries, and the tips were advanced 20 to 30 cm. Catheters and electrode leads were exteriorized through the maternal flank and stored in a cloth pouch; the laparotomy was then repaired. A catheter was placed in a maternal carotid artery and advanced; placement in the left ventricle was confirmed at surgery when a left ventricular waveform was ap-

parent on an R711 dynograph chart recorder (Beckman Instruments, Inc., Fullerton, Calif.). The maternal jugular vein and left ventricular catheters were wrapped in gauze and secured to the neck with a loosely wrapped elastic bandage. Antibiotics were administered to the fetus (chloramphenicol, 100 mg/kg), intrauterine space (penicillin, 600,000 U), and ewe (penicillin, 400,000 U administered intramuscularly). Each ewe was then placed in a clean pen and given free access to food and water for the 5-day recovery period.

Experimental protocol. On the day before the experiment, each ewe was moved to the laboratory area and housed in a mobile pen. All experiments were performed at approximately the same time of day. On the morning of the experiment a 1 ml maternal arterial sample was removed for determination of blood gas tensions, pH, and hematocrit on a pH and blood gas analyzer (System 1302, Instrumentation Laboratory, Inc., Lexington, Mass.) and a Select-A-Fuge 24 centrifuge (Bio-Dynamics, Indianapolis). Measurements were made at 37° C and converted by algorithm to appropriate values at 39° C. Pressure signals were calibrated on the PIDAS data acquisition system (PIDAS, Ithaca, N.Y.) and pressure transducers (models P23KL and P23Db, Gould, Inc., Oxnard, Calif.) with use of a mercury manometer. The uterine electrodes were connected to a junction box that fed signals to the PIDAS unit through a low-pass filter set at 50 Hz. Analog signals were digitized on line and averaged every 5 seconds. Both analog and digital signals were recorded on magnetic tape. Analog signals were also recorded on a chart recorder (model 711, Beckman).

Prostaglandin E_2 (Sigma Chemical Company, St. Louis) and terbutaline sulfate (Brethine, Taylor Pharmaceutical Co.) solutions were prepared from saline stock solutions on the day of each experiment. Prostaglandin E_2 was diluted with saline to a 12.5 μg/ml solution. Terbutaline was diluted with saline solution to yield two separate drug concentrations, 83.3 and 20 μg/ml.

Prostaglandin E_2 (22.4 ± 2.3 μg/min) was infused through the left ventricular catheter for 3 minutes. The dose was increased until a pressure response ≥5 mm Hg and uterine electric activity of at least 4 minutes' duration was elicited.[10]

When the appropriate prostaglandin E_2 dosage was determined, a second control challenge at the same dosage was repeated 30 minutes later. The responses to these two challenges were averaged to obtain a control value.

Seventeen minutes later, when the intrauterine pressure and uterine electric activity had returned to resting levels, terbutaline infusion was started. A loading dose was administered through the jugular vein at 8.5 μg/min for 3 minutes. A maintenance infusion was then given at 2 μg/min for the next 30 minutes. This dosage was selected from the low end of the dosage spectrum for clinical application.[5, 11]

Three more prostaglandin E_2 challenges were repeated in 30-minute intervals throughout the experiment. During terbutaline infusion, a challenge was given that began 20 minutes before the end of the infusion period and at 10 minutes and again at 40 minutes after the terbutaline infusion ended.

Data analysis. Data were read from the digital tape on a VAX VMS 8600 (Digital Equipment Corp., Maynard, Mass.) mainframe computer. The voltage readings were converted to digital pressure values from the electric signals recorded during the calibration procedure. Appropriate data segments were imported to an IBM XT (International Business Machines Corp., Boca Raton, Fla.) personal computer and stored on hard disks.

Polygraph records were examined to define the response period after each prostaglandin E_2 infusion. Five segments of data were extracted, including two control periods, terbutaline infusion, 10 minutes after the end of terbutaline treatment, and 40 minutes after the termination of infusion. Data segments were not of equal length. Segment length was determined by the duration of the prostaglandin E_2 response. If no response occurred, the average duration of the control responses was used to determine segment length. Uterine electromyogram and intrauterine pressure values were referred to the average values for the minute preceding each prostaglandin E_2 challenge.

Integrated responses were determined during each data segment, and each value was calculated as the sum of all activity that occurred in response to prostaglandin E_2 challenge minus the product of the sum of all activity that occurred in the 1-minute quiescent period before the response and the duration of the response to prostaglandin E_2. This calculation was performed to evaluate the combined effects of the magnitude and duration of each response and is expressed as the percent of the average control response. Fetal arterial pressure (referred to intrauterine pressure) and maternal arterial pressure were also determined during each response period. All data are expressed as mean ± SEM.

Statistical analysis was performed by two-way analysis of variance for repeated measures for the main effects of time versus measure (intrauterine pressure vs electromyogram response) on uterine activity. The Huynh-Feldt correction was applied throughout where appropriate.[12] Analysis of variance for repeated measures was used to examine the time-related effects of terbutaline infusion on maternal and fetal blood pressures. Differences between control and test values were tested by analysis of variance for contrast variables when the repeated-measures test was significant. Differences between intrauterine pressure and electromyogram responses were examined by the paired t test with the

Bonferroni correction for the critical value[18] when the interaction of time and measure in the two-way analysis of variance test was significant. For all tests, $p \leq 0.05$ was considered a significant reason to reject the null hypothesis.

Results

Studies were performed on five pregnant ewes at 130 ± 1 days' gestation. Maternal arterial pH (7.50 ± 0.01), P_{CO_2} (36.0 ± 1.7 mm Hg), P_{O_2} (110.0 ± 9.0 mm Hg), and hematocrit (29.5% ± 1.5%) were all within the normal range for this laboratory and indicate that the ewes were healthy and had recovered from surgery.

Maternal and fetal arterial pressure, intrauterine pressure, and uterine electromyogram were monitored continuously. Responses to prostaglandin E_2 challenge were quantitated before, during, and at 10 and 40 minutes after terbutaline infusion.

Neither maternal nor fetal arterial blood pressures demonstrated a significant change from control values at any time during the experiment. Fetal blood pressure (referenced to intrauterine pressure) averaged 50.3 ± 1.8 mm Hg during the control periods, and maternal blood pressure was 82 2 ± 3.9 mm Hg.

The contractile and electric responses to prostaglandin E_2 infusion were assessed by examination of the changes in intrauterine pressure and uterine electromyogram, respectively, during the control and terbutaline infusion periods and at 30-minute intervals after infusion. Two-way analysis of variance of the percent of control values for uterine electromyogram and intrauterine pressure responses to prostaglandin E_2 with time revealed a significant effect of time ($p \leq 0.0001$). This analysis also revealed a significant ($p \leq 0.05$) interaction between time and measurement (intrauterine pressure vs uterine electromyogram). These data are presented in Fig. 1 for both the intrauterine pressure and uterine electromyogram responses.

During the terbutaline infusion period the integrated intrauterine pressure response to prostaglandin E_2 infusion was 13.6% ± 5.5% of the average control value ($p \leq 0.0001$). The response remained significantly lower than that of control (47.2% ± 11.1%) during the prostaglandin E_2 challenge 10 minutes after the termination of the terbutaline infusion ($p \leq 0.01$). However, 40 minutes after the infusion period, the contractile response was not different from control (103.4% ± 16.9%).

During terbutaline infusion, electric activity, as measured by the uterine electromyogram response to prostaglandin E_2 challenge, fell to 7.8% ± 3.6% of the response elicited during the control period ($p \leq 0.0001$). During the 10- and 40-minute challenges, the integrated uterine electromyogram activity was not different from control (102.7% ± 17.9% and 108.9% ± 10.0%, respectively).

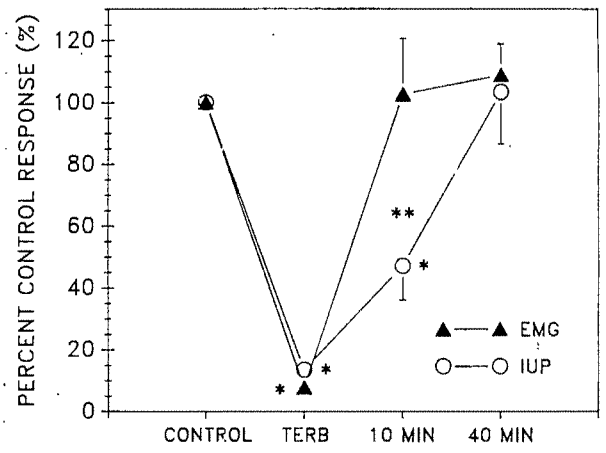

Fig. 1. Effect of terbutaline infusion ($n = 5$) on integrated uterine electromyogram *(EMG)* and intratuerine pressure *(IUP)* responses to prostaglandin E_2 challenge before *(control)*, during *(TERB)*, and at 10 minutes *(10 MIN)* and 40 minutes *(40 MIN)* after terbutaline infusion. *Asterisk*, Difference from control values ($p \leq 0.01$). *Two asterisks*, Differences between intrauterine pressure and electromyogram responses ($p \leq 0.01$) during single prostaglandin E_2 challenge. Data are shown as mean ± SEM.

When the paired t test was applied to each prostaglandin E_2 response, a significant difference was apparent between the uterine electromyogram and intrauterine pressure response to prostaglandin E_2 during the 10-minute challenge ($p \leq 0.01$). Although the integrated uterine electromyogram response was 102.7% ± 17.9% of control, the intrauterine pressure response was 47.2% ± 11.1% of control.

The responses of an individual animal throughout the experiment are shown in Fig. 2. The rise in intrauterine pressure and the increase in uterine electric activity in response to prostaglandin E_2 challenge during the control period are demonstrated in panel 1. Panel 2 shows the diminished electric and contractile activities during the terbutaline infusion period. In the third panel, which shows the response 10 minutes after infusion, the contractile response is still attenuated but the electric activity has already returned to control levels. Finally, panel 4 demonstrates that both variables returned to control values 40 minutes after infusion.

Comment

The effect of terbutaline sulfate infusion on the uterine response to prostaglandin E_2 stimulation was examined in five late-gestation ewes. The ewes were considered to be fully recovered from surgery as indicated by arterial blood gas tensions, pH, and feeding behavior. Prostaglandin E_2 was selected to stimulate uterine contractions because it can be given at discrete intervals

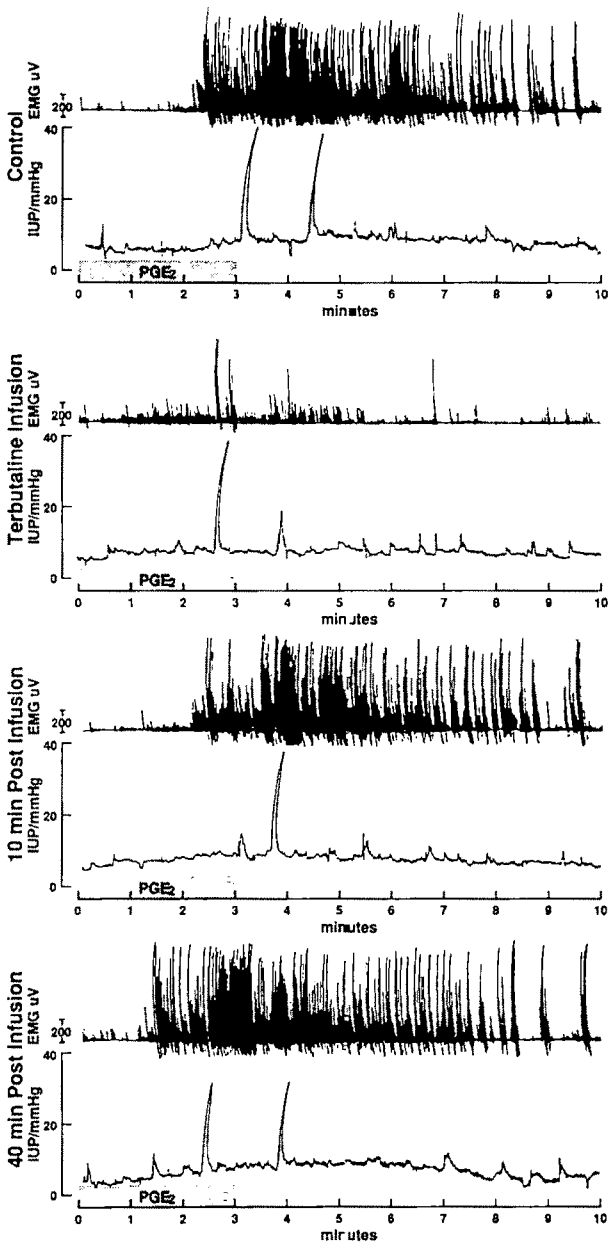

Fig. 2. Effect of terbutaline on electric and contractile responses to prostaglandin E_2 challenge in individual animal. Raw data are shown from control period, infusion period, and 10 and 40 minutes after terbutaline was infused. Uterine electromyogram is presented in *upper tracing*, and intrauterine pressure is shown in *lower tracing* in each panel.

whereas oxytocin challenge causes a protracted and unmanageable response.[8] Within 2 minutes of the beginning of a prostaglandin E_2 challenge, both the uterine electromyogram and intrauterine pressure responses are apparent; these responses are essentially simultaneous. These parameters usually return to baseline levels within 10 minutes of the termination of prostaglandin E_2 infusion. The prostaglandin E_2 stimulus can be repeated at regular intervals with no tachyphylaxis.[8]

This study reveals information that suggests a dual uterine response to the tocolytic properties of terbutaline. The early phase occurred during terbutaline infusion when both the contractile and electric responses to uterine stimulus were attenuated. The recovery phase appeared during the prostaglandin E_2 challenge administered 10 minutes after termination of the terbutaline infusion. The intrauterine pressure response to prostaglandin E_2 was approximately half the strength of the response before terbutaline treatment, and the magnitude of the uterine electromyogram signal was not different from the control values. These data indicate that the recovery time for contractility is slower than that for excitability when the intact ovine uterus is exposed to the tocolytic effects of terbutaline infusion.

In general, β-adrenergic receptors are thought to mediate smooth muscle relaxation by two pathways. First, the generation of spontaneous action potentials is suppressed by β-adrenergic receptor stimulation. For example, low concentrations of isoproterenol (4×10^{-7} mol/L) have been reported to cause cell membrane hyperpolarization that could be blocked by propranolol, as well as a fall in the membrane response to electric stimulus in isolated preparations of the pregnant rat myometrium.[14, 15] The intracellular mechanism for this action is not understood.[7] Second, the mechanical response to those action potentials generated is greatly reduced; that is, excitation-contraction coupling is weakened.[7] In vivo exposure of the myometrial cells of the gravid guinea pig to isoproterenol (1×10^{-5} mol/L) results in no effect on the membrane potential or membrane resistance in comparison with the evoked potentials before β-adrenergic receptor stimulation, although the contractile response was reduced to one half the intensity of the control responses.[16] This action may be mediated by cyclic adenosine monophosphate–stimulated increases in calcium sequestration, by increased calcium efflux, and/or by phosphorylation of the myosin light-chain kinase.[17] Thus, although the uncoupling between excitation and contraction in response to a β-adrenergic receptor agonist has not been previously reported in the intact pregnant uterus, this phenomenon has widespread support from the results of in vitro studies in the myometrium. We submit that attenuation of electric response and the uncoupling of excitation from contraction are separate effects of β-adrenergic receptor agonists that can exhibit different time courses.

We conclude that the uterine response to terbutaline tocolytic therapy in the gravid sheep consists of two phases. During infusion both electric and contractile

activity are diminished. In the recovery phase the electric response to prostaglandin E_2 is normal and contractile activity is depressed.

Catecholamines modulate epidermal growth factor–induced prostaglandin E_2 production in amnion-like (WISH) cells by means of a cyclic adenosine monophosphate–dependent pathway

Hsing-Chih Su, BS,[a] Richard H. Fertel, PhD,[a] and Douglas A. Kniss, PhD[b]
Columbus, Ohio

OBJECTIVE: The purpose of this study was to test the hypothesis that catecholamines can modulate epidermal growth factor–induced prostaglandin E_2 production in amnion-derived cells via a cyclic adenosine monophosphate–dependent pathway.
STUDY DESIGN: Human amnion-derived WISH cells were used as the model system to study the regulation of prostaglandin E_2 production. The concentrations of prostaglandin E_2 and cyclic adenosine monophosphate were measured by radioimmunoassay. Statistical significance was determined with the Student *t* test.
RESULTS: Preexposure of WISH cells to either epinephrine, norepinephrine, or dopamine inhibited epidermal growth factor–induced prostaglandin E_2 production. In addition, propranolol blocked both the increase in cyclic adenosine monophosphate accumulation and the inhibition of prostaglandin E_2 production caused by epinephrine.
CONCLUSIONS: These results indicate that epidermal growth factor–induced prostaglandin E_2 production can be attenuated by preexposure of amnion cells to catecholamines and that the inhibitory effect of catecholamines on epidermal growth factor response may be mediated via a β-adrenergic receptor–coupled adenylate cyclase. (Am J Obstet Gynecol 1992;166:236-41.)

Key words: Amnion, catecholamines, epidermal growth factor (EGF), cyclic adenosine monophosphate (cAMP), prostaglandin E_2 (PGE_2), WISH cell

The mechanisms of human labor are not clearly understood, but prostaglandins (PGs) are thought to play a central role in the initiation and maintenance of cervical changes and myometrial contractions.[1-3] Several studies have shown that PGs (especially PGE_2 and $PGF_{2\alpha}$) found in the amniotic fluid increase with gestation and with the progression of labor.[4] Many investigators now believe that the amnion is a major source of amniotic fluid PGE_2.[1-3] The processes that regulate the production of PGs during labor are still undefined, but the signal for the initiation of labor is thought to emanate from the fetus.[5] One possible source of control is epidermal growth factor (EGF), which is a single-chain polypeptide of 6045 d that can stimulate the growth of a variety of tissues[6, 7] and may be secreted by the fetal kidney to provide a signal for initiating labor. Evidence that EGF may be important in human labor is based on the observation that the median concentration of EGF in amniotic fluid from women in labor is significantly higher than that in a control group of nonlaboring women.[8]

The importance of EGF in labor is further supported by the observation that EGF stimulates PGE_2 production by cultured amnion cells.[9] This effect of EGF does not preclude the possibility that other substances found in amniotic fluid may also influence PGE_2 biosynthesis in the amnion. Because the concentration of catecholamines increases in amniotic fluid during late pregnancy,[10, 11] these agents might also influence PGE_2 production. Our study was designed to test the hypothesis that catecholamines can modulate EGF-induced PGE_2 production by amnion cells by means of a β-adrenergic–coupled receptor, cyclic adenosine monophosphate (cAMP)–dependent pathway.

Material and methods

Cell cultures. WISH cells derived from amnion tissue were obtained from the American Type Culture Collection (ATCC CCL25). The cells were cultured in a mixture of Ham's F-12 and Dulbecco's modified Eagle medium (F12/DMEM) (1 : 1, vol/vol) with the addition

of 10% newborn calf serum, 2 mmol/L L-glutamine, 1 mmol/L sodium pyruvate, and 50 μg/ml gentamicin and were incubated at 37° C in 5% carbon dioxide and 95% air. The growth medium was changed every 2 days. When confluence was reached, the cell cultures were subcultured at lower density for use. Cells were plated in 24-well plates (2×10^5 cells per well) or 12-well plates (5×10^5 cells per well), and all experiments were conducted after 2-days growth, at which time the cells were 85% to 90% confluent.

Pretreatment studies. Cells growing in 24-well culture plates were rinsed once with 1 ml of serum-free F12/DMEM medium. The cells were then preincubated with 0.5 ml of growth medium in the presence or absence of test substances for 4 hours at 37° C. After the pretreatment phase, cells were treated with or without 10 ng/ml EGF for an additional 4 hours at 37° C. Thereafter the medium was collected and frozen at −70° C before PGE_2 determination.

PGE_2 determination. The PGE_2 concentration in the culture medium was determined by specific radioimmunoassay with antiserum prepared by inoculating domestic chickens with PGE_2–keyhole limpet hemocyanin conjugate. The details of the assay have been published elsewhere.[12]

cAMP accumulation. Cells growing in 12-well plates were rinsed once with 2 ml of F-10 medium (F12) with the addition of 15 mmol/L (N-[2-hydroxyethyl]piperazine-N′-[2-ethanesulfonic acid]) and 1 mg/ml bovine serum albumin (F10-HEPES/BSA). The cells were then incubated with 1 ml of F10-HEPES/BSA medium in the presence or absence of test substances for the indicated time. The reaction was stopped by the addition of 2 ml 10% trichloroacetic acid into each well; the trichloroacetic acid solution was then collected and frozen at 70° C before cAMP determination.

cAMP determination. The trichloroacetic acid samples were extracted three times with a 1 : 3 (vol/vol) ratio of sample to water-saturated ethyl ether to remove trichloroacetic acid. Any remaining ether was removed by a 10-minute incubation in a 57° C water bath. cAMP concentration was then measured by a modification of the radioimmunoassay procedure of Steiner et al.[13]

Protein determination. Cell protein was measured by the method of Lowry et al.[14]

Statistical analysis. Statistical significance was determined with the unpaired, two-tailed Student *t* test. Data were presented as mean ± SEM of six replicates per condition.

Materials. All tissue culture reagents were from GIBCO (Grand Island, N.Y.). Human recombinant epidermal growth factor was from Upstate Biotechnology Institute (Lake Placid, N.Y.). [5,6,8,11,12,14,15-^{3}H(N)] PGE_2 was purchased from Amersham (Arlington Heights, Ill.). Iodine 125–cAMP was obtained from the laboratory of Dr. Sue O'Dorisio, Columbus Children's Hospital, Columbus, Ohio. cAMP antiserum was developed in our laboratory and is sensitive enough to measure 10 fmol cAMP. Epinephrine, (±)-propranolol, dibutyryl adenosine 3′:5′ cyclic monophosphate (dibutyryl cAMP), forskolin, and 3-isobutyl-1-methylxanthine (IBMX) were obtained from Sigma Chemical Company, St. Louis.

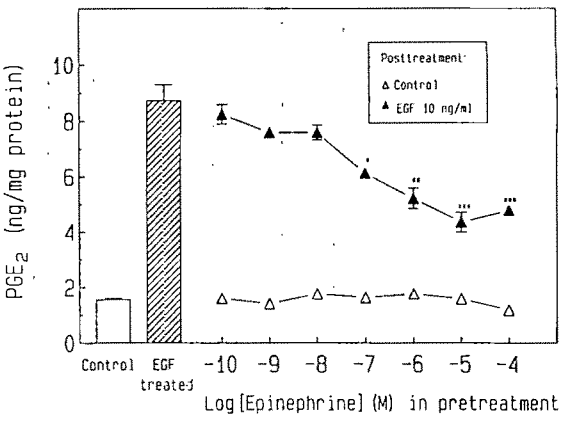

Fig. 1. Dose-dependent effect of epinephrine on EGF-induced PGE_2 production. Two days after plating, WISH cells were preincubated for 4 hours with indicated concentrations of epinephrine in F12/DMEM/10% newborn calf serum medium. After preincubation, cells were rinsed once with serum-free F12/DMEM medium and then exposed to F12/DMEM/10% newborn calf serum medium in presence or absence of 10 ng/ml EGF for an additional 4 hours. The concentration of PGE_2 in the medium was determined by radioimmunoassay. Data are presented as mean ± SEM of six replicates per condition from one of two separate experiments. (*Control,* Cells received medium only at both treatment phases; *EGF treated,* cells received medium at pretreatment phase and 10 ng/ml EGF at posttreatment phase. *One asterisk,* $p < 0.05$; *two asterisks,* $p < 0.001$; *three asterisks,* $p < 0.0001$; all compared with EGF treatment only.)

Results

Effect of catecholamines on EGF-induced PGE_2 production by amnion cells. Our initial results confirmed the earlier finding that EGF stimulates PGE_2 production by amnion cells in a time- and dose-dependent manner.[15, 16] In WISH cells the increase in PGE_2 production begins 1 hour after EGF treatment and reaches a maximum after a 4-hour exposure to EGF (data not shown). Under these conditions EGF at a concentration of approximately 10 ng/ml caused maximal stimulation approximately threefold to fourfold over control. On the basis of these results we conducted subsequent experiments with a concentration of 10 ng/ml EGF and a 4-hour incubation period. To test the hypothesis that catecholamines alter EGF-induced PGE_2 production in amnion cells, we incubated cells with various concentrations of catecholamines for 4 hours before an additional 4-hour exposure to EGF. Our results indicate that although exposure to concentrations of 10^{-10} to

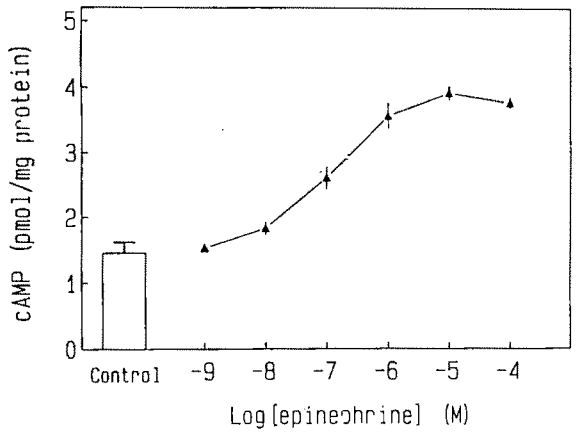

Fig. 2. Dose-dependent effect of epinephrine on cAMP accumulation in WISH cells. Two days after plating, WISH cells were incubated for 5 minutes with 5×10^{-5} mol/L IBMX and indicated concentrations of epinephrine in F10/HEPES/BSA medium. After 5-minute incubation, 10% trichloroacetic acid was added to plates to stop cAMP metabolism. cAMP concentration was determined by radioimmunoassay. Data represent mean ± SEM of six replicates per condition from one of two separate experiments. (*Control,* Cells received IBMX only.)

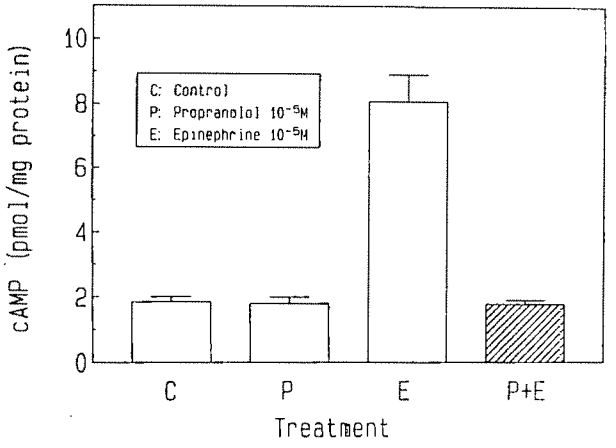

Fig. 3. Effect of propranolol on epinephrine-stimulated cAMP accumulation in WISH cells. Two days after plating, WISH cells were preincubated for 5 minutes with 10^{-4} mol/L IBMX in presence or absence of 10^{-5} mol/L propranolol in F10/HEPES/BSA medium. After preincubation phase, 10^{-5} mol/L epinephrine was added to some wells for an additional 5 minutes. After 5-minute incubation, 10% trichloroacetic acid was added to plates to stop cAMP metabolism. cAMP concentration was determined by radioimmunoassay. Data represent mean ± SEM of six replicates per condition. (*C,* Cells received IBMX only; *P,* cells received IBMX and propranolol; *E,* cells received IBMX and epinephrine; *P + E,* cells received IBMX, propranolol, and epinephrine.)

10^{-4} mol/L of epinephrine alone had little effect on PGE_2 production by WISH cells, EGF-induced PGE_2 production was inhibited by prior exposure of the cells to epinephrine (Fig. 1). Epinephrine at concentrations below 10^{-8} mol/L caused no significant effect on the EGF response. However, epinephrine at 10^{-7}, 10^{-6},

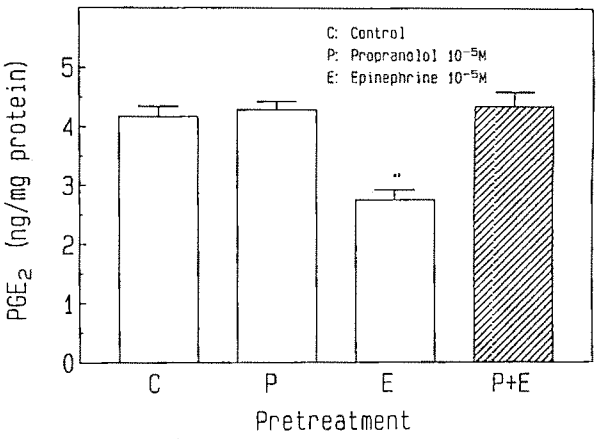

Fig. 4. Effect of propranolol on epinephrine-induced decrease in PGE_2 production in response to EGF. Two days after plating, WISH cells were preincubated for 30 minutes with or without 10^{-5} mol/L propranolol in F12/DMEM/10% newborn calf serum medium. After 30-minute incubation, 10^{-5} mol/L epinephrine was added to some wells for 3½ hours. After total 4-hour preincubation, cells were rinsed once with serum-free F12/DMEM medium and then exposed to 10 ng/ml EGF in F12/DMEM/10% newborn calf serum medium for an additional 4 hours. Concentration of PGE_2 in medium was determined by radioimmunoassay. Data represent mean ± SEM of six replicates per condition. (*C,* Control—cells received medium only in pretreatment period. All four groups received 10 ng/ml EGF in posttreatment period.)

10^{-5}, and 10^{-4} mol/L caused decreases of 30.1% ($p = 0.0012$), 40.6% ($p = 0.0003$), 50.4% ($p < 0.0001$), and 44.2% ($p < 0.0001$), respectively, in EGF-induced PGE_2 production. Similarly, norepinephrine and dopamine alone had little effect on PGE_2 production but inhibited EGF-induced PGE_2 production in a dose-dependent manner (data not shown). On the basis of these experiments we concluded that preexposure of amnion cells to catecholamines inhibits PGE_2 production in response to EGF.

Role of cAMP in inhibitory effect of catecholamines on EGF-induced PGE_2 production. Because cAMP has been shown to influence PG synthesis in a number of tissues,[17, 18] it is of interest to determine whether the inhibitory effect of catecholamines on EGF-induced PGE_2 production is dependent on cAMP accumulation. To test the hypothesis that the effect of catecholamines is the result of their ability to increase cAMP in WISH cells, WISH cells were exposed to epinephrine at concentrations ranging from 10^{-9} to 10^{-4} mol/L for 5 minutes. Our results indicate that epinephrine caused a dose-dependent increase in cAMP accumulation in WISH cells (Fig. 2). This increase was blocked by propranolol (Fig. 3). At a concentration of 10^{-5} mol/L, propranolol was able to completely eliminate the epinephrine-stimulated increase in cAMP accumulation.

From these experiments it is clear that the epinephrine-induced increase in WISH cell cAMP is by means

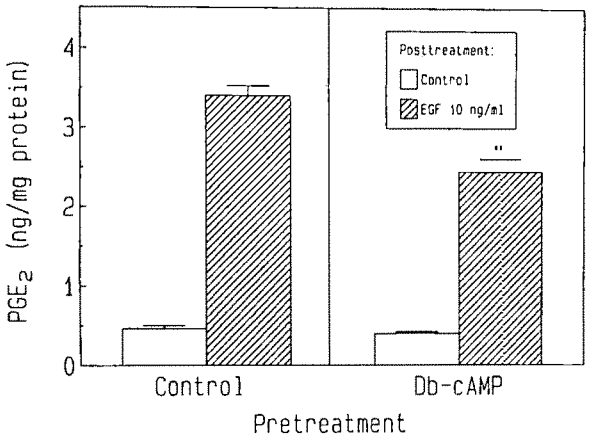

Fig. 5. Effect of cAMP analog on EGF-induced PGE_2 production. Two days after plating, WISH cells were preincubated for 4 hours with or without 5×10^{-5} mol/L dibutyryl cAMP in F12/DMEM/10% newborn calf serum medium. After preincubation phase, cells were rinsed once with serum-free F12/DMEM medium and then exposed to F12/DMEM/10% newborn calf serum medium in presence or absence of 10 ng/ml EGF for additional 4 hours. Concentration of PGE_2 in medium was determined by radioimmunoassay. Data represent mean ± SEM of six replicates per condition from one of two separate experiments. (*Control*, Cells received vehicle only.)

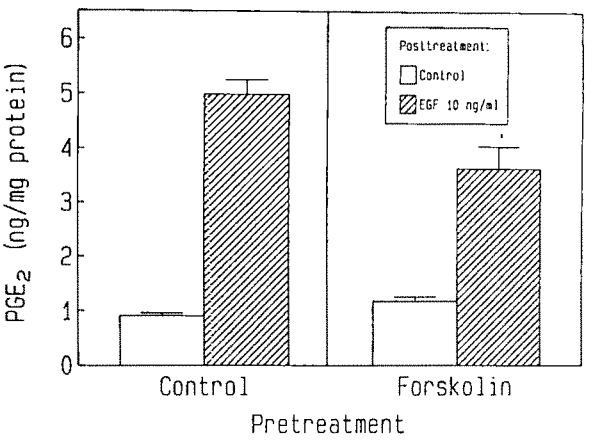

Fig. 6. Effect of adenylate cyclase activator on EGF-induced PGE_2 production. Two days after plating, WISH cells were preincubated for 4 hours with or without 5×10^{-5} mol/L forskolin in F12/DMEM/10% newborn calf serum medium. After preincubation phase, cells were rinsed once with serum-free F12/DMEM medium and then exposed to F12/DMEM/10% newborn calf serum medium in presence or absence of 10 ng/ml EGF for additional 4 hours. Concentration of PGE_2 in medium was determined by radioimmunoassay. Data represent mean ± SEM of six replicates per condition from one of two separate experiments. (*Control*, Cells received vehicle only.)

of the β-adrenergic receptor. We next determined the effect of propranolol on the epinephrine-induced decrease in PGE_2 production. WISH cells were exposed to propranolol 30 minutes before epinephrine pretreatment. Our results indicate that 10^{-5} mol/L propranolol was able to block the inhibitory effect of epinephrine on EGF-induced PGE_2 production (Fig. 4). This is in accord with the previous result that propranolol at the same concentration eliminated the stimulatory effect of epinephrine on cAMP accumulation. Because propranolol blocked both the increase in cAMP accumulation and the inhibition of PGE_2 production that resulted from epinephrine, we conclude that the inhibitory effect of epinephrine on EGF-induced PGE_2 production may be mediated by means of an adenylate cyclase–coupled β-adrenergic receptor.

The effect of cAMP-stimulating agents on EGF-induced PGE_2 production. To confirm that the inhibitory effect of catecholamines on PGE_2 production in response to EGF was by means of a cAMP-dependent pathway, WISH cells were pretreated with a cAMP analog (5×10^{-5} mol/L dibutyryl cAMP), an adenylate cyclase activator (5×10^{-6} mol/L forskolin), or a phosphodiesterase inhibitor (5×10^{-5} mol/L IBMX) for 4 hours before EGF exposure. Our results indicate that all three agents reduced PGE_2 production in response to EGF (Figs. 5 to 7). As with epinephrine, none of these three cAMP-stimulating agents alone had a significant effect on PGE_2 production. On the basis of these experiments, we conclude that cAMP caused a

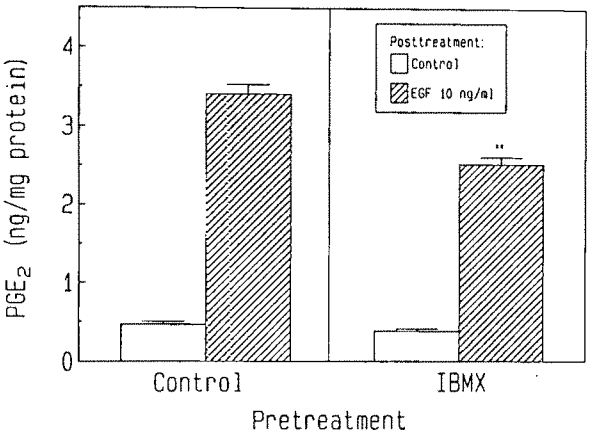

Fig. 7. Effect of phosphodiesterase inhibitor on EGF-induced PGE_2 production. Two days after plating, WISH cells were preincubated for 4 hours with or without 5×10^{-5} mol/L IBMX in F12/DMEM/10% newborn calf serum medium. After preincubation phase, cells were rinsed once with serum-free F12/DMEM medium and then exposed to F12/DMEM/10% newborn calf serum medium in presence or absence of 10 ng/ml EGF for additional 4 hours. Concentration of PGE_2 in medium was determined by radioimmunoassay. Data represent mean ± SEM of six replicates per condition from one of two separate experiments. (*Control*, Cells received vehicle only.)

decrease in EGF-induced PGE_2 production. Our results suggest that preexposure of amnion cells to catecholamines inhibits EGF-induced PGE_2 production and that this inhibitory effect may be by means of β-adrenergic receptor–coupled adenylate cyclase.

Comment

Human amnion has been proposed to be a target tissue for labor-initiating signals emanating from the fetus.[3, 19] It is also considered to be a major source of PGs (primarily PGE_2) produced by intrauterine tissue at term.[20, 21] Because the synthesis and metabolism of PGs in human amnion cells grown in monolayer cultures are similar to those in amnion tissue,[22, 23] these cells are useful as a model for the study of the regulation of PG synthesis. Although primary amnion cell cultures are very useful and have been used by several laboratories, different culture preparations may vary considerably. In this study we used a human amnion cell line (WISH) as the model system with which to investigate the regulation of PGE_2 production. Recent studies from our laboratory[24] suggest that WISH cells are an effective model for the study of EGF-induced PGE_2 production. In addition, a study by Harris et al.[16] also used WISH cells to investigate amniotic PGE_2 production.

Previous studies have identified EGF receptors in many tissues, including fetal membranes[25] and human amnion (WISH) cells.[26] In addition, EGF alters amnion function by increasing PGE_2 production in a time- and dose-dependent manner.[15, 16] Because concentrations of catecholamines increase in amniotic fluid during late pregnancy[10, 11] and because there are functional β-adrenergic receptors in human amnion tissue,[27] it is reasonable to hypothesize that EGF plays a critical role in the initiation of human labor by stimulating PGE_2 production in amnion cells and that this effect can be modulated by catecholamines. In fact, our results indicate that, although preexposure of amnion cells to catecholamines alone does not alter PGE_2 production, these agents do inhibit EGF-induced PGE_2 production. Because propranolol attenuates this inhibitory response, the effect is probably mediated via a β-adrenergic receptor. However, a previous study by Warrick et al.[17] reported that β-adrenergic receptor agents and cAMP-stimulating agents stimulate PGE_2 output from dispersed cells of amnion tissues. Their observation differs both from our finding and from the study by Casey et al.,[15] which showed that dibutyryl cAMP and isoproterenol fail to trigger PGE_2 production in primary human amnion cell culture. This suggests that the observed difference between our finding and that of Warrick et al. is not solely due to our use of the WISH cell line. Our observation that β-adrenergic receptor agents can decrease the production of the labor-inducing factor (PGE_2) is in accord with previous observations that β-adrenergic receptor agonists can inhibit uterine activity in preterm labor.[28]

In this study we have provided evidence to support a central role for EGF and a modulating role for catecholamines in the control of PGE_2 production by amnion-derived cells in vitro. Our results suggest that in the human amnion cell line (WISH) catecholamines stimulate the accumulation of cAMP, which, in turn inhibits PGE_2 production in response to EGF. This indicates that the EGF-induced PGE_2 biosynthesis pathway is negatively modulated by adenylate cyclase. Because catecholamines only partially inhibit the EGF effect, it is likely that PGE_2 production is influenced by other factors as well. For example, our previous studies[24] have shown that activators of protein kinase C augment EGF-induced PGE_2 production in amnion cells. This suggests the possibility of a complex link between adenylate cyclase and protein kinase C in amnion cells.

We thank Monica Summers for her technical assistance and Drs. Steven G. Gabbe and Jay D. Iams for their continued support of this work.

Circulating hyaluronic acid in nonpregnant, pregnant, and postpartum guinea pigs: Elevated levels observed at parturition

Mohammad R. Rajabi, MD, PhD,[a, c] Edward W. Quillen, Jr., PhD,[a]

OBJECTIVE: Dilatation of the uterine cervix at parturition is associated with an increase in cervical hyaluronic acid content. The objective is to test the hypothesis that circulating hyaluronic acid is increased at parturition.
STUDY DESIGN: Serum hyaluronic acid levels from nonpregnant (n = 5), pregnant (n = 13), and postpartum (n = 4) adult Hartley guinea pigs were determined with a radiometric assay that utilizes iodine 125–labeled hyaluronic acid–binding protein. Results were analyzed for statistical significance with Student's paired t test and regression analysis.
RESULTS: The serum hyaluronic acid level in nonpregnant animals was 238 ± 88 ng/ml (mean ± SEM). During pregnancy, serum hyaluronic acid levels were 127 ± 12 and 126 ± 34 ng/ml at 25 and 50 to 63 days' gestation, respectively. At parturition, hyaluronic acid levels increased fivefold to 765 ± 111 ng/ml ($p < 0.001$). Hyaluronic acid levels returned to antepartum values 2 days post partum (153 ± 27 ng/ml). There was no significant difference between arterial and venous levels.
CONCLUSION: Circulating hyaluronic acid levels increase significantly at parturition in the guinea pig.
(AM J OBSTET GYNECOL 1992;166:242-6.)

Key words: Hyaluronic acid, parturition, guinea pig

Hyaluronic acid (hyaluronan) is a linear polysaccharide of high molecular weight (1 to 4 × 10^6 d), which is widely distributed throughout the body. Its voluminous structure and its inherent stiffness resulting from its molecular size and hydration result in a profound viscoelasticity that may be important in structural integrity and function of connective tissues.[1] It is synthesized at the plasma membrane by a membrane-bound hyaluronic acid synthetase.[2] It is present in the tissue as a coat attached to cell surface, as a scaphoid for aggregation of proteoglycans, or as a free polymer.[3] It enters the circulation by lymphatic drainage and is endocytosed by endothelial cells of liver, where it is digested.[4] Elevated circulating levels of hyaluronic acid are present in liver cirrhosis (decreased removal), rheumatoid arthritis, scleroderma, and cancer (increased production).[5-8]

The biologic function of hyaluronic acid in the body is poorly understood. It modulates many cellular functions such as cell migration,[9] invasion,[10, 11] proliferation,[12, 13] transformation,[14] and mitosis.[15] A wide variety of agents have been shown to increase hyaluronic acid synthesis in culture, including insulin, testosterone, prostaglandins, interleukin-1, cyclic adenosine monophosphate, lipopolysaccharides, platelet-derived growth factor, and epidermal growth factor. Hyaluronic acid synthesis is inhibited by glucocorticoids, estrogen, and adenosine.[3]

Pregnancy is a state of active cellular growth and differentiation in the fetus, accompanied by marked remodeling of maternal reproductive organs. Perhaps the most dramatic change in tissue structure in the mother is the rapid dilatation of the uterine cervix at parturition. The cervix is regarded as a fiber-reinforced composite viscoelastic material, because it is made of elastic solid (collagen) and viscous macromolecules (proteoglycans).[16, 17] Stress-strain studies have shown that in the nonpregnant rat the maximum possible dilatation of the cervix is a 50% increase in internal diameter without rupture,[18] accompanied by an overall reduction in strength and stiffness at parturition (in the rat) of the order of 20-fold to 40-fold.[17] However, the cervix in all mammals undergoes a severalfold increase in diameter at parturition without rupture. This remarkable alteration in the biomechanical properties of the cervix can only be explained by a major change in its biochemical composition.

Biochemical changes in the cervix at parturition include a 50% reduction in collagen content, a twofold increase in hyaluronic acid, and a sixfold to 14-fold increase in collagenase, accompanied by active degra-

dation of type I collagen (the predominant collagen in the cervix) in the extracellular matrix in women and in the guinea pig.[19-22] The marked increase in cervical collagenase at delivery is associated with a significant increase in circulating collagenase at term and in premature deliveries in women.[23] We hypothesized that parturition may be accompanied by a similar increase in circulating hyaluronic acid in the guinea pig. This study confirms this hypothesis.

Material and methods

Serum. Blood from anesthetized animals (see below) was collected by intracardiac puncture. Serial arterial and venous blood samples were simultaneously collected by withdrawing 1 ml aliquots from jugular and carotid catheters. The blood was allowed to clot for 30 minutes at room temperature. Serum was separated by centrifugation 365*g* for 10 minutes at 4° C and frozen at −20° C until analyzed for hyaluronic acid.

Animals. Adult Hartley guinea pigs (Charles River Breeding Laboratories, Montreal) were housed in guinea pig cages (three to five animals per cage) and fed guinea pig chow and water as described. All pregnant animals were of known gestational ages. Timed pregnancies were induced by mating animals during the fertile period immediately post partum.

Surgical procedure. Animals were equipped with indwelling vascular catheters as follows. Guinea pigs were catheterized while they were under general anesthesia with ketamine (40 mg/kg) and xylazine (1 mg/kg) intramuscularly. The shoulder and ventral neck regions were clipped, and the jugular vein and carotid artery were exposed aseptically. Vascular catheters were constructed of 0.02 × 0.06 Tygon microbore tubing (Norton Plastics, Akron, Ohio) with a tension-fit intravascular tip (1 cm) of 0.58 × 0.96 mm vinyl tubing (Dural Plastics, Dural, New South Wales, Australia). Catheters were funneled subcutaneously to the shoulder where approximately 5 cm of tubing protruded from the skin. The neck incision was closed, and patency of the catheters was maintained by daily flushing with saline solution. The dead space of the catheters was filled with heparin (1000 U/ml of saline solution) at the end of each flushing, and the catheters were sealed with a stainless steel wire plug.

Hyaluronic acid assay. A radiometric assay for hyaluronic acid determination was used (Pharmacia HA test 50) as described by the manufacturer. Hyaluronic acid standards (10 to 1000 ng/ml) or serum samples (25 to 100 μl) were incubated in duplicate with iodine 125–hyaluronic acid binding protein for 60 minutes at room temperature. The unbound ^{125}I-hyaluronic acid binding protein was removed by incubation with hyaluronic acid–Sepharose for 45 minutes. After addition of 2 ml of the washing solution, the mixture was centrifuged at 2000*g* for 10 minutes. This washing step was repeated and the supernatant was discarded. The radioactivity of the precipitate was measured in a γ-counter.

Calculation of results. The counts (B) for standards and unknown were expressed as a percentage of the mean counts of the hyaluronic acid–free standard (Bo).

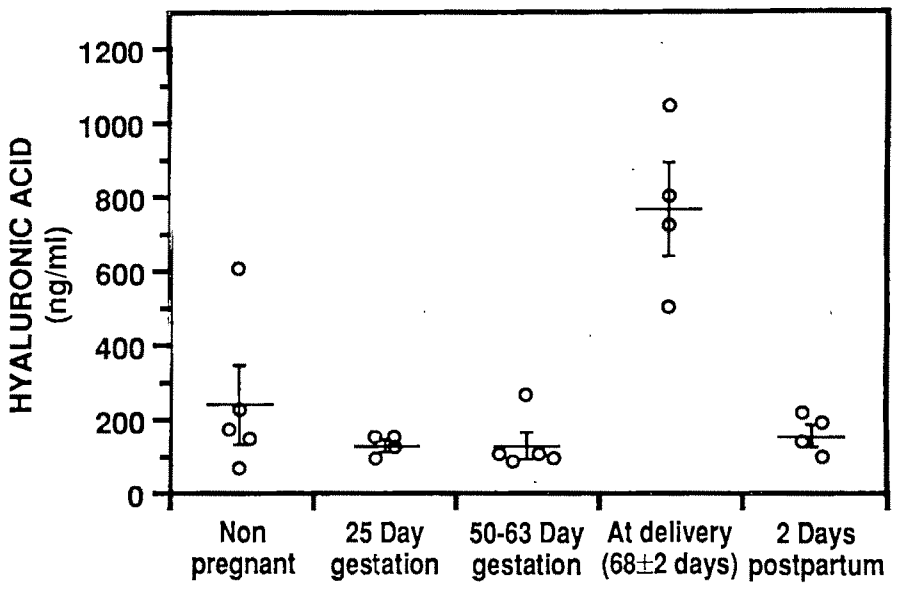

Fig. 2. Hyaluronic acid *(HA)* levels in sera from cardiac puncture were assayed as described in Material and Methods. *Horizontal lines,* Means; *vertical lines,* standard error of mean. $p < 0.001$ at delivery versus 25 to 63 days' gestation.

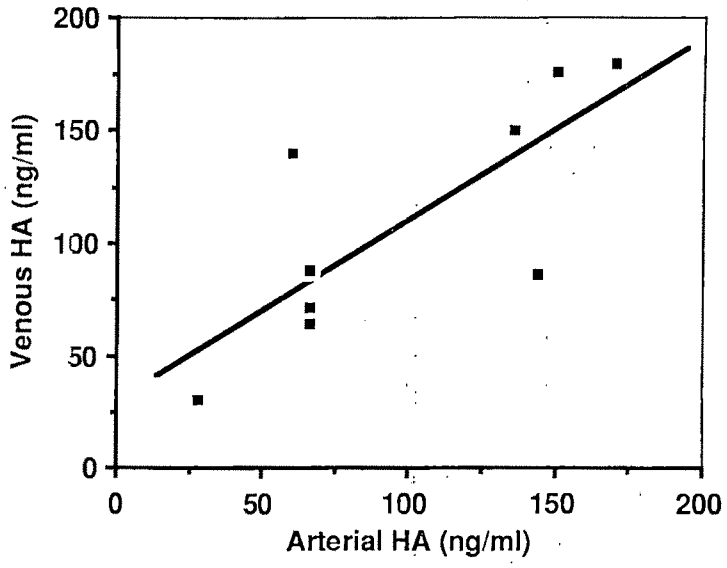

Fig. 3. Distribution of hyaluronic acid *(HA)* in circulation of guinea pigs that were 50 days pregnant. Venous hyaluronic acid = 121% ± 5.7% compared with arterial hyaluronic acid (mean ± SEM, $n = 9$, not statistically significant). Correlation coefficient between two vascular compartments is 0.77.

Percent activity bound = (B × 100)/Bo. The percentage binding for the standards was plotted against the hyaluronic acid concentration, and a standard curve was constructed (Fig. 1). The concentration of the unknown samples was read from the standard curve. The lower limit of detection for guinea pig serum of the assay is 10 ng/ml of serum. Coefficient of variation was 11% between assays and 9% within assays.

Statistical analysis. The significance of differences between mean values were determined by the Student paired t test. A value of $p \leq 0.05$ was considered significant. Regression analysis was used to examine the correlation between venous and arterial blood samples.

Results

Circulating hyaluronic acid. Concentrations of hyaluronic acid are shown in Fig. 2. The level in nonpregnant animals decreased during pregnancy. Low

levels continued to be present until day 63 of gestation. At parturition, there was a significant fivefold increase in hyaluronic acid levels ($p < 0.001$). Levels 2 days post partum returned to antepartum levels.

Distribution of hyaluronic acid in the circulation. The correlation between levels in arterial and venous samples is presented in Fig. 3 ($r = 0.77$). Venous samples contained more hyaluronic acid than did arterial samples (mean ± SEM 121% ± 5.7%, $n = 9$). This difference, however, was not statistically significant.

Comment

In this article we report on the changes in the level of circulating hyaluronic acid in the guinea pig pregnancy and at parturition. Nonpregnant animals have much higher levels than previously reported for nonpregnant healthy women.[6] This may be due to species differences. Levels during pregnancy did not change significantly from day 25 to day 63 of gestation. Hyaluronic acid during pregnancy may play a role in the growth and development of the placenta.[24] Of significance is the fivefold increase at delivery. Circulating hyaluronic acid has a half-life of 2.5 to 5 minutes because of its rapid uptake and metabolism in the liver.[3] The marked increase in steady-state levels at birth represents either a decrease in removal or an increase in production or mobilization from the extracellular matrix. There is no evidence that liver function is impaired at parturition. Thus the increase in hyaluronic acid probably results from an increase in production or mobilization from the extracellular matrix into the circulation by lymphatic drainage. Although the origin of hyaluronic acid in the circulation is not known, the observed increase at parturition may result in part from the increased content or mobilization of hyaluronic acid from the extracellular matrix of the cervix and the lower uterine segment at parturition.

In ovariectomized pregnant rats (day 18 to 22 of gestation) treated with progesterone and 17β-estradiol, the administration of highly purified porcine relaxin resulted in a significant increase in cervical hyaluronic acid content.[25] The surge of hyaluronic acid at parturition may be caused by an increase of relaxin at that time. Prostaglandins have been reported to increase hyaluronic acid biosynthesis; therefore it is possible that the observed increase at birth may be mediated by an increase in prostaglandins.[8] An accumulation of hyaluronic acid in the extracellular matrix may result in the observed softening and swelling of the organ because of its unique viscoelastic properties and its high avidity for water. An increased content in the cervix accompanied by active collagen degradation by collagenase[21-23] is associated with a marked alteration of the structural rigidity and tensile strength of the cervix leading to rapid cervical dilatation. The source of circulating hyaluronic acid and its role in the process of cervical dilatation, however, remain to be determined.

Change in electrocardiogram T-wave amplitude during umbilical cord compression is predictive of fetal condition in sheep

Sendai, Japan

OBJECTIVE: The purpose of this study is to assess the usefulness of the dynamic change in T/QRS ratio in fetal electrocardiograms in predicting the fetal condition when repetitive variable decelerations are seen in intrapartum cardiotocograms.
STUDY DESIGN: We investigated the relationship, using linear regression and Wilcoxon's test, between T/QRS and blood gas values, catecholamine concentrations, and blood pressure during repetitive cord compression in five chronically instrumented lamb fetuses.
RESULTS: T/QRS during cord compression correlated significantly ($p < 0.01$) with fetal arterial pH ($r = -0.7711$), norepinephrine concentration ($r = 0.7551$), and duration of elevated blood pressure during compression ($r = -0.8619$). Fetal arterial pH and base excess were lower, the duration of elevated blood pressure during compression was shorter, and carbon dioxide partial pressure and catecholamine concentrations were higher in the stage with higher (>0.50) T/QRS during compression ($p < 0.005$).
CONCLUSION: We can estimate the severity of fetal distress by measuring T/QRS near the bottom of the decelerations. (Am J Obstet Gynecol 1992;166:246-55.)

Key words: Fetal electrocardiogram, variable deceleration, umbilical cord compression, fetal acidemia, catecholamines

Today fetal heart rate (FHR) monitoring is widely used for intrapartum surveillance. Among the various patterns seen during FHR monitoring, variable decelerations are frequently observed during labor[1] and are considered to be caused by umbilical cord compression.[2,3] In the clinical setting, fetal distress is diagnosed on the basis of the depth and duration of the variable decelerations.[2,4] However, we sometimes encounter the case in which fetal compromise is not predictable by either the depth or the duration of the variable decelerations alone.[5-7] Therefore additional or alternative methods are necessary to evaluate fetal acidemia when repetitive variable decelerations are seen repeatedly in intrapartum FHR monitoring.

It is reported that fetal hypoxemia induced by allow-

ing the ewe to breathe a low-oxygen mixture[8-10] or by reducing the aortic blood flow of the ewe[11, 12] results in a progressive increase in T-wave amplitude in the fetal electrocardiogram (ECG). However, change in T-wave amplitude during umbilical cord compression and its alteration as fetal acidemia develops has not been reported.

In this study we attempted to induce decelerations in the FHR recording by repeated umbilical cord compression using chronically instrumented lamb fetuses. We then observed the change in T-wave amplitude, as the T/QRS ratio, in the fetal ECG during cord compression and the ways in which it altered as fetal acidemia developed. The relationship between T/QRS and fetal arterial gas values, catecholamine concentrations, and fetal blood pressure during compression were also investigated during repeated cord compression.

The aim of the current study was to assess the usefulness of the dynamic change in T/QRS in fetal ECG in predicting fetal arterial gas values, blood pressure, and catecholamine concentrations when repetitive variable decelerations are seen in FHR monitoring.

Material and methods

The experiments were performed on five chronically instrumented lamb fetuses of known gestational age, ranging between 125 and 134 days (mean 130.0 days), carried by ewes of mixed breed. After the animals fasted for at least 24 hours, a midline abdominal incision was made with the ewes under general anesthesia (nitrous oxide and halothane) with tracheal intubation. After exteriorization of the fetus, polyvinyl catheters (outer diameter 2.0 mm, inner diameter 1.2 mm) were inserted aseptically into the fetal carotid artery and jugular vein with the animals under local anesthesia. Tripolar cardioelectrodes were stitched subcutaneously to the bilateral axilla and the right hind leg of the fetus. A vascular occluder with an inflatable balloon (OC-16, In Vivo Metric Inc., Healdsburg, Calif.) was placed around the umbilical cord near the fetal abdomen. After surgical procedures on the fetus had been completed, the fetus was returned to the uterus, and a polyvinyl catheter was inserted into the amniotic cavity before closure of the uterus and abdominal wall of the ewe. The catheters and cables were led directly out from the incision wound. The ewe's activity, food and water intake, and urine and excrement production were assessed daily. The arterial catheter was infused continuously with heparin solution (0.1 IU/ml) to maintain patency of the catheter. Antibiotics (mainly ABPC) were administered into the maternal vein, amniotic cavity, and fetal vein daily during the postoperative period.

The experiments were performed after the fourth postoperative day. We designed the repetitive cord compression, as shown in Fig. 1, to induce gradually developing fetal acidemia. The cord was compressed by inserting sterile saline solution into the balloon of the occluder for 40 seconds, followed by a period of 80 seconds' release. We performed this set of procedures 15 times and followed it with 60 seconds of compression and 60 seconds of release for zero (two experiments), five (two experiments), and 10 (one experiment) repetitions. The number of compressions in each experiment ranged from 15 to 25 (mean 20), and the total duration of each experiment was 30 to 50 minutes. Umbilical arterial blood flow completely ceased within 3 to 4 seconds after the beginning of saline solution insertion, as confirmed by measuring umbilical arterial blood flow with an ultrasonographic transit-time flowmeter (T101 Transonic Systems Inc., Ithaca, N.Y.).[13] Samples of 0.6 to 0.8 ml of blood were taken before the experiments and immediately after the release of every fifth cord compression. Blood gases were analyzed with an AVL 940 system (AVL AG, Schaffhausen, Switzerland) with temperature correction to 39° C. Base excess was calculated with this system. After blood gas analyses, blood plasma was separated by centrifugation and stored frozen at −80° C until assayed.

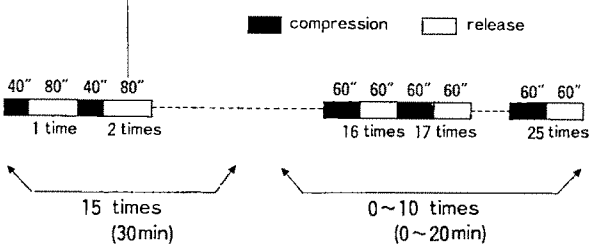

Fig. 1. Experimental procedure for repeated umbilical cord compression.

Plasma norepinephrine and epinephrine levels were measured in 50 μl plasma samples by means of the single-isotope radioenzymatic assay, as modified by Peuler and Johnson.[14] The sensitivity was 40 pg/ml for norepinephrine and 28 pg/ml for epinephrine. The assay was linear for values up to 20,000 pg/ml, with a slight decrease in linearity from 20,000 to 60,000 pg/ml. The within-run coefficient of variation did not exceed 14%. Reproducibility was monitored by inclusion of a plasma pool (norepinephrine 357 ± 27 pg/ml, epinephrine 28 ± 7 pg/ml; mean ± sd).

FHR was monitored with a cardiotachometer triggered by the cardioelectric signal. Fetal arterial pressure was measured with pressure transducers (model P23ID, Gould, Inc., Oxnard, Calif.; model 4-327-I, Bell & Howell, Inc., Pasadena, Calif.) and was corrected for intrauterine pressure. Fetal ECG (obtained by unipolar limb lead, similar to the aVF lead in humans), heart

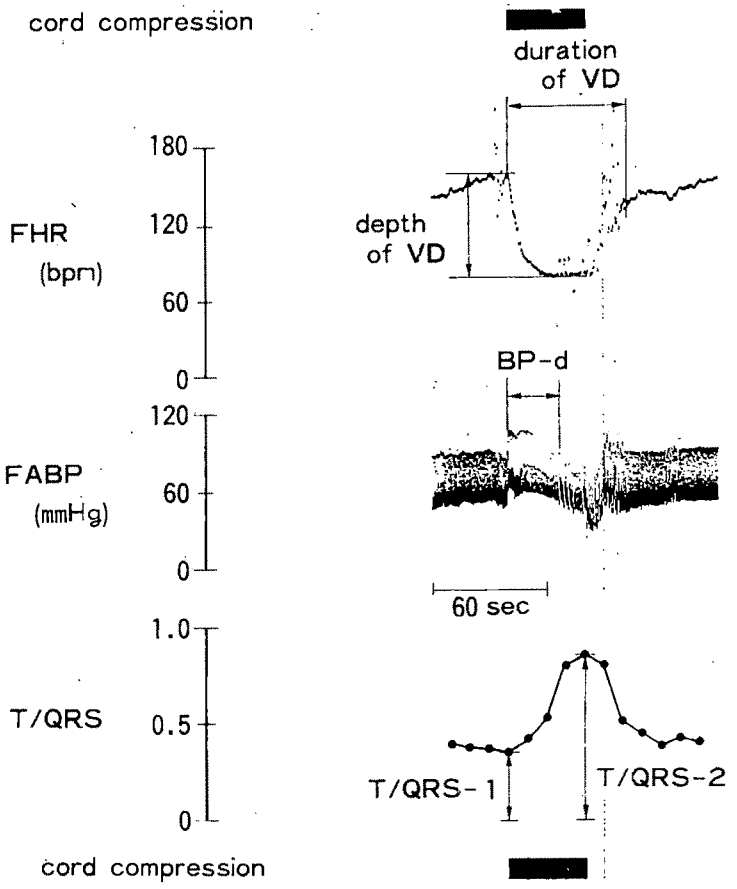

Fig. 2. Measurements of duration of elevated fetal blood pressure *(BP-d)* and T/QRS ratio from fetal ECG. *T/QRS-1,* T/QRS just before compression; *T/QRS-2,* T/QRS during (40 seconds after start of) compression.

rate, and fetal arterial pressure were recorded continuously on a pen recorder (Recti-Horiz 8K NEC, Sanei Instruments Co., Ltd., Tokyo) and data recorder (A49 Sony Magnescale Inc., Tokyo).

Changes in the T wave of the fetal ECG were expressed as the ratio of the amplitude of the T wave to that of the QRS complex (T/QRS). T/QRS was measured just before (T/QRS-1) and at the point 40 seconds after the start (T/QRS-2) of every fifth compression (Fig. 2). Duration of elevated blood pressure during cord compression was measured from the onset of the rise in systolic blood pressure immediately after the start of cord compression until the systolic pressure decreased to the precompression value. Correlations of T/QRS (both T/QRS-1 and T/QRS-2) with fetal arterial gas values, catecholamine concentrations, and duration of elevated blood pressure during compression were investigated.

In analyzing the data, the mean and standard deviation were calculated. Wilcoxon's rank sum test was used to calculate statistical significance. Correlations of T/QRS with other variables (gas values, catecholamine concentrations, and duration of elevated blood pressure during cord compression) were derived by linear regression.

Results

Five experiments were performed on five fetuses. Mean fetal arterial pH before the experiment was 7.303 (range 7.262 to 7.342). Mean plasma norepinephrine and epinephrine concentrations at the start of experiments were 1142 (range 690 to 1906) and 121 (range 17 to 296) pg/ml, respectively.

Fig. 3 shows the change in fetal arterial gas values during the experiments. Fetal arterial pH and base excess decreased gradually during the experiment. P_{O_2} dropped first and changed little after that. P_{CO_2} increased gradually in most cases.

Although the plasma norepinephrine and epinephrine levels continued to rise up to the fifteenth or twentieth compression, thereafter they reached a plateau at a pH of around 7.15 (Fig. 4).

Fig. 5 shows how FHR pattern, fetal arterial pressure, and T/QRS in fetal ECG altered as fetal acidemia de-

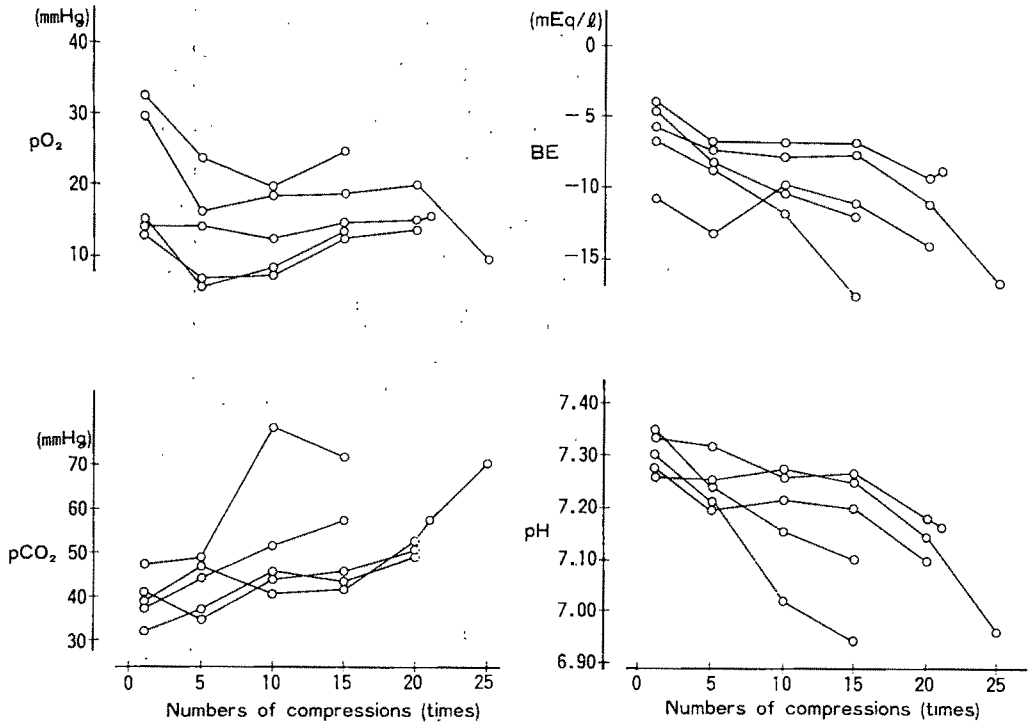

Fig. 3. Change in fetal arterial P_{O_2}, P_{CO_2}, base excess *(BE)*, and pH during experiment.

veloped. By compressing the umbilical cord repeatedly, repetitive deceleration could be observed on FHR monitoring. Each deceleration started a few seconds after the start of cord compression and recovered gradually after release of the compression. The depth and duration of decelerations remained almost unchanged as the fetus became acidotic. At the beginning of the experiment, fetal arterial blood pressure increased suddenly, immediately after the start of cord compression, and persisted during the compression period. However, as the fetus became acidotic, fetal arterial blood pressure gradually dropped during the compression period. T/QRS was measured every 10 seconds and plotted on the chart. T/QRS did not change much during cord compression at the beginning of the experiment. However, as fetal acidemia developed, T/QRS increased gradually after the start of cord compression and returned to the precompression value with the release of compression, just the mirror image of FHR deceleration. Further, this change in T/QRS during cord compression became more prominent as fetal acidemia progressed further.

We investigated the changes in T/QRS at two points, one just before the compression (Fig. 2, T/QRS-1) and another 40 seconds after the start of compression (T/QRS-2), as mentioned previously. In FHR recording, these points are just before the onset of deceleration (T/QRS-1) and during deceleration (T/QRS-2). Both T/QRS-1 and T/QRS-2 increased gradually during the experiment (Fig. 5).

Fig. 6 shows the relationship between T/QRS-2 and fetal arterial pH. There was a negative linear significant correlation between them ($r = -0.7711$, $p < 0.01$). The relationships between T/QRS-2 and P_{CO_2} and duration of elevated blood pressure during cord compression are shown in Fig. 7 ($r = 0.7383$, $p < 0.01$) and in Fig. 8 ($r = -0.8619$, $p < 0.01$), respectively. In Fig. 9 the relationship between duration of elevated blood pressure during cord compression and pH is presented. There were strong correlations between these variables ($r = -0.9024$, $p < 0.01$). Other calculated correlation coefficients for T/QRS versus fetal variables (arterial gas values, plasma catecholamine concentrations, and duration of elevated blood pressure during cord compression) are listed in Table I. T/QRS correlated well with pH, P_{CO_2}, base excess, norepinephrine concentrations, and duration of elevated blood pressure during cord compression. No significant correlation was found between T/QRS and P_{O_2}. Duration of elevated blood pressure during cord compression correlated strongly with pH, as mentioned above.

Sensitivities, specificities, and predictive values in prediction of fetal acidemia by T/QRS are calculated and listed in Table II. Table III shows the difference in fetal arterial gas values, catecholamine concentra-

tions, and blood pressure during cord compression between two groups divided according to whether T/QRS-2 was >0.50. pH and base excess were higher, blood pressure during cord compression was longer, and P_{CO_2} and catecholamine concentrations were lower in the group in which T/QRS was <0.50 than in the group in which T/QRS was >0.50.

Comment

Variable decelerations in intrapartum FHR monitoring are thought to be caused by umbilical cord compression.[2, 3, 15] We previously observed variable decelerations in chronically instrumented lamb fetuses by compressing the umbilical cord repeatedly. In that experiment we found gradually progressing fetal acidemia, an increase in fetal catecholamine concentrations, and progress in fetal hypotension during cord compression, as the fetus became acidotic by repeated cord compression.[15] Regarding the progress in fetal acidemia seen in repetitive variable decelerations, Kubli et al.[4] stated that the fetus becomes acidotic when the nadir of variable decelerations is <70 beats/min or the duration of variable decelerations is >60 seconds. However, the depth or duration of variable decelerations does not always predict the pH of umbilical blood or neonatal Apgar score[5] in the clinical setting. Also in fetal sheep we observed only a weak correlation ($r = -0.337$) between arterial pH and depth of variable decelerations.[15]

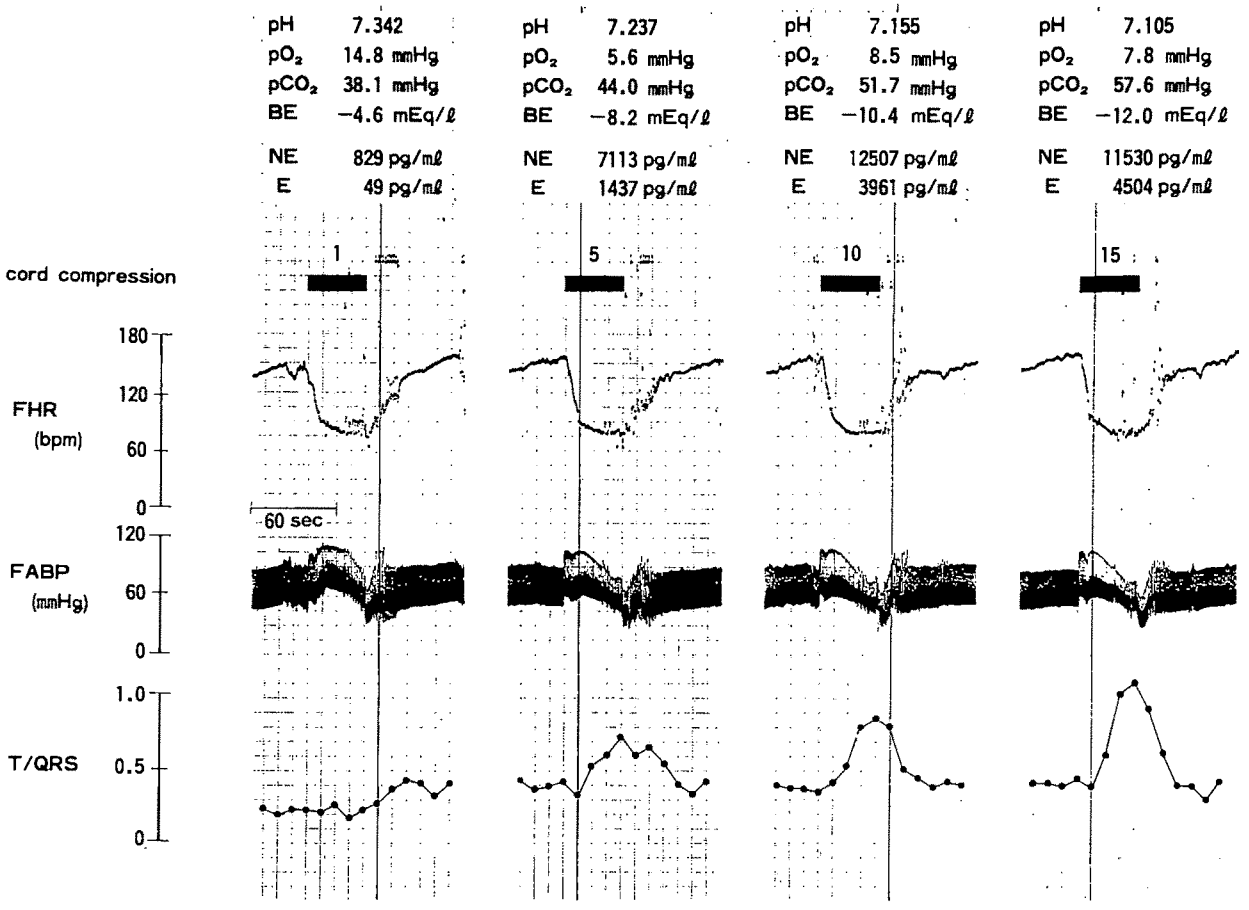

Fig. 5. Changes in FHR patterns, fetal arterial blood pressure *(FABP)*, T/QRS, fetal arterial gas values, and catecholamine concentrations with repeated umbilical cord compression. *BE*, Base excess; *NE*, norepinephrine; *Epi*, epinephrine.

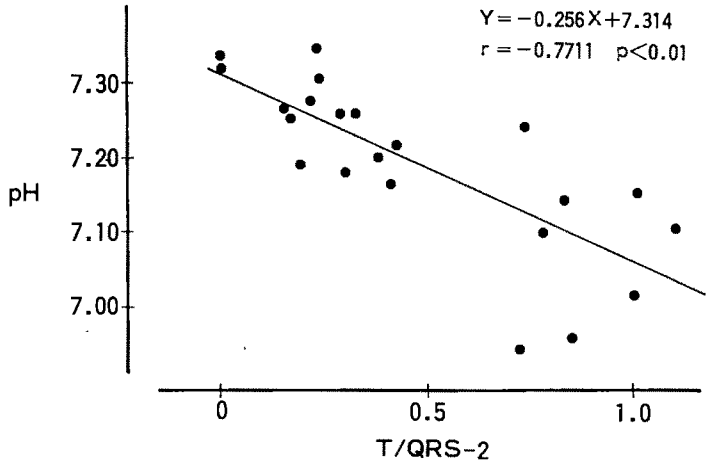

Fig. 6. Correlation between T/QRS during compression (T/QRS-2) and fetal arterial pH.

As a result, when repetitive variable decelerations are seen in FHR monitoring, the fetus may be acidotic, and cardiovascular function may be altered. Thus it is necessary to estimate the severity of fetal acidemia or altered cardiovascular function by evaluating parameters other than the depth or the duration of variable decelerations. In the current study we attempted to estimate the severity of fetal distress (progress in fetal

acidemia, increase in catecholamine concentrations and decrease in blood pressure during compression) by observing the change in T/QRS in fetal ECG when repetitive variable decelerations were produced by compressing the umbilical cord repeatedly in lamb fetuses.

T/QRS just before compression (T/QRS-1) correlates with fetal arterial pH, P_{CO_2}, base excess, catecholamine concentrations, and duration of elevated blood pressure during cord compression (Table I). T/QRS during compression (T/QRS-2) also correlates with fetal arterial pH (Fig. 6), P_{CO_2} (Fig. 7), catecholamine concentrations, and duration of elevated blood pressure during cord compression (Fig. 8). Thus we can estimate the severity of acidemia, catecholamine concentrations, and the decrease in fetal blood pressure during compression by observing T/QRS during and before the cord compression.

Several investigations into the change in T/QRS of fetal ECG during prolonged hypoxia have been performed in experimental animal studies. In mild hypoxia, change in T/QRS is thought to be mediated by activation of β-adrenergic receptors, because these changes in T/QRS are blocked by injection of the β-adrenergic receptor–blocking agent propranolol.[16] During severe hypoxia, change in T/QRS is considered to be a direct result of myocardial hypoxia, which causes metabolic acidosis with lactate accumulation.[9, 16] Rosen et al.[10] reported correlations between T/QRS and epinephrine concentrations and stated that an increase in T/QRS indicates an anaerobic switch in myocardial metabolism. Hoekegard et al.[8] found a relationship between T/QRS and myocardial glycogen by direct myocardial biopsy. In all, elevation of T/QRS by hypoxia indicates a negative energy balance in cardiac metabolism followed by anaerobic breakdown of glycogen.

With respect to periodic hypoxic stress, Widmark et al.[12] compressed the aorta of the ewe for 60 seconds and found that T/QRS increased significantly, without acidemia, because of the compression and returned to the precompression value after the release of compression. On the contrary, we found only a small change in T/QRS by umbilical cord compression when the fetus was not acidotic at the beginning of the experiment. However, as the fetus became acidotic, T/QRS during compression gradually increased with cord compression (Fig. 5). We speculate that without acidemia, elevated blood pressure persists during the compression period, maintaining coronary flow and compensating for the fall in arterial P_{O_2}, but when fetal acidemia develops, fetal blood pressure decreases during cord compression (Figs. 5 and 9), causing a decrease in coronary flow, which, together with the decrease in P_{O_2}, diminishes oxygen supply to the myocardium. These speculations are supported by the strong negative correlations ($r = -0.8619$, $p < 0.01$) between T/QRS-2 and duration of elevated blood pressure during cord compression in Fig. 8. Because duration of elevated blood pressure during cord compression correlated well ($r = -0.8569$, $p < 0.01$) with P_{CO_2} (Table I), we speculate that decrease in fetal blood pressure during cord compression is due to myocardial depression caused mainly by respiratory acidemia.

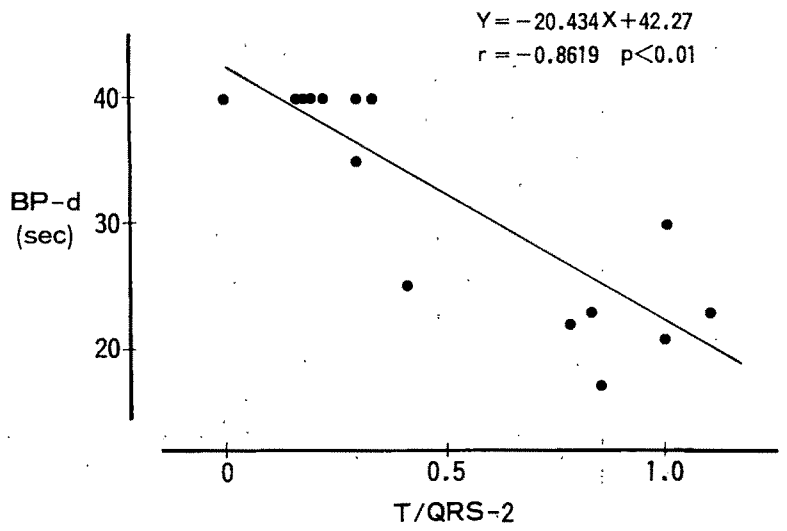

Fig. 8. Correlation between T/QRS during compression (T/QRS-2) and duration of elevated blood pressure *(BP-d)*.

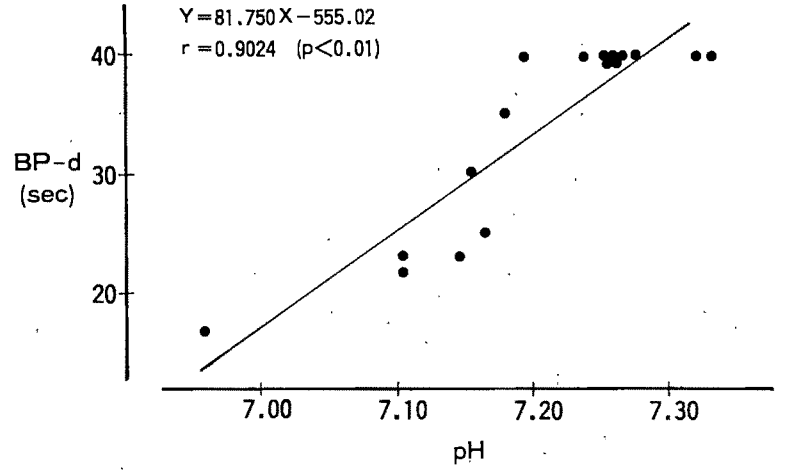

Fig. 9. Correlation between duration of elevated blood pressure *(BP-d)* and fetal arterial pH.

In clinical work several investigations with fetal scalp electrodes have been performed regarding the change in T/QRS during labor.[17-20] Lilja et al.[19] observed the fetal ECG with a microprocessor and reported that a T/QRS ratio <0.25 appeared to be a reliable sign of fetal well-being. Regarding the relationship between FHR pattern and the change in T/QRS, Pardi et al.[18] reported that an increased T-wave amplitude appeared in 15% of severe variable decelerations and in 48% of late decelerations; however, they did not show any definite relationship between T-wave height and fetal biochemical status. Further, there have been no observations reported relating to T/QRS criteria during FHR deceleration by which one can predict fetal acidemia when decelerations appear in FHR monitoring.

For the purpose of predicting fetal acidemia (pH < 7.15), we calculate the sensitivity, specificity, and predictive values of T/QRS (both T/QRS-1 and T/QRS-2) shown in Table II. T/QRS-1 and T/QRS-2 values of 0.30 and 0.50, respectively, are reliable criteria for predicting fetal acidemia.

T/QRS-2 correlated well with catecholamine concentrations, as shown in Table I; therefore we can estimate fetal catecholamine concentrations by measuring T/QRS during decelerations. Fetal catecholamines are essential in redistributing cardiac output to vital organs when hypoxia occurs. Lorijn and Longo[21] reported that in fetal lambs redistribution to vital organs occurs when norepinephrine concentrations are about 4500 pg/ml by continuous infusion. Table III shows the difference in pH, catecholamine concentrations, and duration of elevated blood pressure during cord compression between two groups divided according to whether the T/QRS values were >0.50. If T/QRS-2 is <0.50, the fetus is not so acidotic, catecholamines can be se-

creted further, and elevated blood pressure is maintained. However, when T/QRS-2 is >0.50, the fetus becomes acidotic and cannot further secrete catecholamines and fetal blood pressure decreases during deceleration. As shown in Fig. 5, the change in T/QRS is just a mirror image of FHR deceleration. Thus T/QRS-2 appears to be almost identical to T/QRS near the bottom of the FHR deceleration. This means that if a T/QRS >0.50 is observed near the bottom of the variable deceleration, fetal reserve to tolerate cord compression appears to be limited, and some kind of intervention may be necessary to prevent fetal compromise.

During human labor we usually obtain the fetal ECG signal by fetal scalp electrode. In that system the sensitivity vector is not parallel to the fetal longitudinal axis. In the current study we used a fetal unipolar limb lead that is similar to aVF, which may be nearly parallel to the fetal longitudinal axis. Thus we cannot apply the findings of this study directly to fetal ECG performed conventionally during labor. A sensitivity vector that is parallel to the fetal vertical axis could be performed by placing electrodes on the fetal scalp and maternal thigh, as Lindecrantz and Widmark[12] have suggested. In that lead ECG waveforms would be similar to that of fetal aVF, and we could apply the findings of the current study to human fetus during labor.

As for changes other than T-wave amplitude in the fetal ECG induced by hypoxia, there are some clinical observations regarding P wave or PQ interval.[17,18] However, there are few observations of these in animal experiments. By umbilical cord compression, change in P wave and PQ interval might occur as a result of vagal stimulation or direct hypoxic effect or catecholamine release. We do not discuss here, however, whether valuable observations might be made of changes in P wave or PQ intervals.

In the current study we examined decelerations caused by repeated cord compression. Further investigations are needed to apply these findings to the case of late decelerations, because there are differences between late and variable decelerations, such as the absence of a sudden increase in fetal blood pressure during deceleration in late decelerations.

In conclusion, when variable decelerations are seen in intrapartum FHR monitoring, fetal condition can be predicted according to whether T/QRS at the bottom of the deceleration is >0.50. Further clinical investigations are needed to apply these findings to intrapartum management.

Changes in human platelet angiotensin II binding sites associated with early pregnancy

Philip N. Baker, DM, Fiona Broughton Pipkin, DPhil, and E. Malcolm Symonds, DM
Nottingham, England

We have demonstrated that in very early pregnancy the elevated levels of the components of the renin-angiotensin system are associated with a significant diminution in platelet angiotensin II binding ($p < 0.01$). (AM J OBSTET GYNECOL 1992;166:255-6.)

Key words: Angiotensin II, pregnancy, platelet membrane glycoproteins, renin-angiotensin system

A cross-sectional study has suggested that the level of human platelet angiotensin II binding sites in pregnancy parallels the diminution in pressor responsiveness to infused angiotensin II, with platelet angiotensin II binding being significantly lower in patients in the first trimester than in nonpregnant women.[1] The purpose of this, the first longitudinal study of platelet angiotensin II binding in pregnancy, was to study further platelet angiotensin II binding levels in early pregnancy.

Thirty nulliparous, normotensive women were recruited for the study, after having been seen by their general practitioners for advice about preconception health care. No subject had been using hormonal contraception for at least 6 months, and all had regular menstrual cycles. All subjects were investigated between days 5 and 9 of the menstrual cycle, because an effect of the menstrual cycle on platelet angiotensin II binding has been demonstrated.[2] Approximately 20 ml of blood was taken from each subject for determination of platelet angiotensin II binding, as previously described.[1] Measurements of plasma angiotensin II, renin substrate, and renin concentration were also performed.

Twelve women (aged 24 to 33 years, median 27) conceived within 1 year of the initial investigation. A blood sample was obtained between weeks 5 and 8 after the last menstrual period, and further samples were obtained at 11 and 18 weeks' gestation.

A significant effect of early pregnancy on platelet angiotensin II binding was found ($p < 0.01$, Friedman

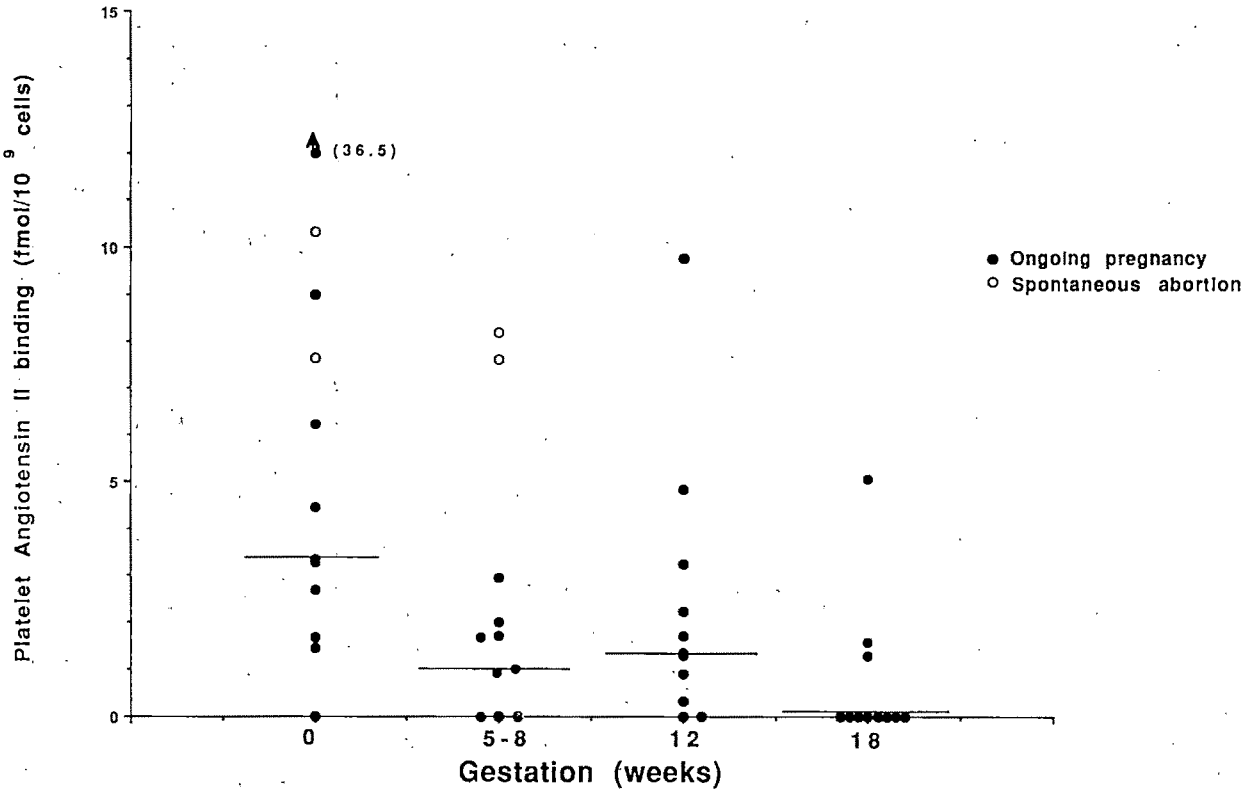

Fig. 1. Human platelet angiotensin II binding in early pregnancy.

analysis of variance) (Fig. 1) Platelet angiotensin II binding at 5 to 8 weeks' gestation (median value 1.2 fmol/10^9 cells) was significantly lower than when measured before conception (3.4 fmol/10^9 cells), and the level at 18 weeks' gestation (0.0 fmol/10^9 cells) was significantly lower than that at 11 weeks' gestation (1.5 fmol/10^9 cells) (in each case $p = 0.02$, Wilcoxon matched-pairs, signed-ranks test).

Plasma angiotensin II levels at 5 to 8 weeks' gestation (median 40.3 pg/ml, range 14.8 to 59.2) were significantly higher than those before conception (12.1 pg/ml, 2.8 to 26.3, $p < 0.02$, Wilcoxon matched-pairs, signed-ranks test), although there were no subsequent significant changes in plasma angiotensin II level. The plasma renin substrate level and plasma renin concentration also rose in early pregnancy, demonstrating a significant effect on both the hormones (in each case $p < 0.01$, Friedman analysis of variance).

Two further women conceived but had spontaneous abortions at 8 and 10 weeks. At 5 to 8 weeks' gestation platelet angiotensin II binding was not reduced (Fig. 1), and the values of plasma angiotensin II were below the median value of the other 12 women.

The diminution in angiotensin II binding to platelets (a suggested model of vascular smooth muscle[1]), which accompanied the elevated levels of the components of the renin-angiotensin system and was demonstrable as early as 5 to 8 weeks' gestation, is thus a very early adaptation to pregnancy. The changes found may represent a continuation of the low binding found in the luteal phase of the menstrual cycle,[2] the return to follicular levels not occurring if the woman conceives.

The maternal and fetal effects of milrinone and dopamine in normotensive pregnant ewes

Stony Brook, Brooklyn, and New York, New York

The safety of milrinone, administered during gestation, was evaluated in seven chronically instrumented pregnant ewes and their fetuses. Each of the following six intravenous regimens was administered in random order: milrinone, 75 $\mu g \cdot kg^{-1}$; over 1 minute, followed by 240-minute infusions of the drug at a rate of 1, 2, or 4 $\mu g \cdot kg^{-1} \cdot min^{-1}$; dopamine 5 or 10 $\mu g \cdot kg^{-1} \cdot min^{-1}$ over 60 minutes; or normal saline solution, 0.5 $ml \cdot min^{-1}$ for 240 minutes. Maternal and fetal acid-base parameters, heart rate, and blood pressure were monitored as were the ewe's venous and intraamniotic pressures and uterine blood flow. Milrinone concentrations determined in maternal arterial blood samples obtained during 1 and 2 $\mu g \cdot kg^{-1} \cdot min^{-1}$ infusions were found to be within the human therapeutic range. Bolus injection of milrinone, as well as the lowest drug infusion, resulted in no significant changes in uterine blood flow, whereas 2 $\mu g \cdot kg^{-1} \cdot min^{-1}$ milrinone infusion led to a 14% to 19% increase in uterine blood flow between 120 and 240 minutes. With the highest milrinone infusion, this increase was approximately 20%. In contrast, with both dopamine infusions, a dose-relatec decrease in uterine blood flow of 15% to 26% occurred between 15 and 60 minutes. No milrinone could be detected in any fetal plasma samples. Fetal arterial pH and blood gas tensions did not change during milrinone infusions. Dopamine 10 $\mu g \cdot kg^{-1} \cdot min^{-1}$ led to a progressive decrease in fetal arterial pH and an increase in $Paco_2$, which may have been related to similar changes in the ewe. It is concluded that milrinone has no adverse effects on uterine blood flow and fetal well-being when administered during ovine pregnancy. (Am J Obstet Gynecol 1992;166:257-62.)

Key words: Cardiotonic drugs, milrinone, dopamine; effects: maternal and fetal; pregnancy, sheep

Vasopressor and inotropic agents, which exert their effects by adrenergic receptor stimulation, may improve maternal cardiovascular status but, at the same time, reduce uteroplacental perfusion.[1-5] Recently formulated bipyridine compounds, amrinone and milrinone, are potent cardiotonic drugs having a different mechanism of action, that is, inhibition of myocardial phosphodiesterase activity.[6] These drugs also have a mild direct pulmonary and systemic vasodilator effect.[6, 7] Little is known of their efficacy and safety during pregnancy. Amrinone has been reported to have no adverse effect on uterine blood flow in the pregnant baboon, but no data regarding plasma concentrations, placental transfer, and/or fetal effects of the drug were presented.[8] Milrinone, a newer agent, is a methyl carbonitril derivative of amrinone.[9] In animal and human tests, its use has resulted in enhanced cardiac performance.[6, 7, 9] Potential advantages of milrinone over amrinone are that it can be formulated in an oral preparation, as well as a parenteral one, and it is less likely to cause side effects, such as gastrointestinal disturbances or thrombocytopenia.[6, 9] To date there have been no reports on the safety of milrinone administered during pregnancy. The current study was undertaken to evaluate the maternal and fetal effects of milrinone in chronically instrumented pregnant sheep.

Material and methods

Pregnant sheep near term of gestation, term being 148 days, were studied according to a protocol approved by the Institutional Animal Care and Use Committee. Details of surgical preparation have been described previously.[10] Briefly, after an overnight fast, ewes were given a spinal anesthetic, tetracaine hydrochloride, 12 to 14 mg, supplemented by a dilute thiopental sodium drip as needed. The maternal abdominal aorta and common iliac vein were cannulated with poly-

ethylene catheters via the femoral vessels. Laparotomy and hysterotomy were then performed for cannulation of the fetal common carotid artery and jugular vein. A catheter was also placed in the amniotic cavity. A 4 mm "R" series pulse transit-time ultrasonographic flow probe (Transonic Systems, Inc., Ithaca, N.Y.), sensitive enough to detect changes in blood flow of at least 10%, was secured around a branch of the uterine artery supplying the pregnant horn. During abdominal closure, all catheters and the flowmeter cable were tunneled subcutaneously and exteriorized within a pouch attached to the ewe's flank. Finally, after local infiltration with 2-chloroprocaine, a 16-gauge venous cannula was inserted percutaneously into the ewe's jugular vein.

Animals were then allowed to recover for at least 4 days, the period of time necessary for flow probe stabilization. Antibiotics were administered twice daily to the mother and fetus throughout the recovery and study period.

On the day of experiment, the ewe was weighed and kept standing in a cart. During a control period of at least 60 minutes and throughout the study, maternal and fetal heart rate and arterial blood pressure were continuously recorded on a polygraph (Siemens Corp., Iselin, N.J.). The ewe's venous pressure (common iliac vein) and intraamniotic pressure were also recorded, as was uterine blood flow. Fetal arterial blood pressure was corrected for changes in intraamniotic pressure.

On separate days, the ewe was given one of the following six regimens in random order: (1) an intravenous injection (jugular catheter) of milrinone 75 $\mu g \cdot kg^{-1}$ over 1 minute, followed by a 240-minute infusion of the drug at a rate of 1 $\mu g \cdot kg^{-1} \cdot min^{-1}$; (2) same milrinone bolus injection followed by a 2 $\mu g \cdot kg^{-1} \cdot min^{-1}$ infusion; (3) same milrinone bolus injection followed by a 4 $\mu g \cdot kg^{-1} \cdot min^{-1}$ infusion; (4) dopamine 5 $\mu g \cdot kg^{-1} \cdot min^{-1}$ infusion over 60 minutes; (5) dopamine 10 $\mu g \cdot kg^{-1} \cdot min^{-1}$ infusion, also over 60 minutes; (6) normal saline solution infused at 0.5 $ml \cdot min^{-1}$ over 240 minutes.

Only a saline solution infusion could be followed by a drug study on the same day but a drug infusion required a recovery period of 1 day. In preliminary studies bolus injections of milrinone 75 $\mu g \cdot kg^{-1}$ followed by 1 or 2 $\mu g \cdot kg^{-1} \cdot min^{-1}$ infusions of the drug were found to result in plasma drug concentrations of 80 to 400 $ng \cdot ml^{-1}$, which correspond to therapeutic levels in human subjects.[9] Dopamine, known to reduce uterine perfusion in a dose-dependent manner,[4] was administered at infusion rates that resulted in a 15% to 25% decrease in uterine artery blood flow in our preliminary studies. The duration of dopamine infusions was limited to 60 minutes to preserve fetal viability.

Arterial blood samples were drawn from the ewe and fetus during the control period and at the end of bolus injection of milrinone. During infusions of milrinone or saline solution, samples were obtained at 5, 15, 30, and 60 minutes and hourly thereafter, up to 240 min. During dopamine administration samples were taken at 15, 30, and 60 minutes. The volume of each fetal blood sample was 1.25 ml in the milrinone 1 and 2 $\mu g \cdot kg^{-1} \cdot min^{-1}$ and 0.25 ml in all other studies. All samples were analyzed for pH and gas tensions with standard microelectrodes. Aliquots obtained from the 1 and 2 $\mu g \cdot kg^{-1} \cdot min^{-1}$ milrinone studies were centrifuged, and plasma was separated and frozen at $-20°$ C to be subsequently analyzed in the laboratories of the Sterling Research Group for milrinone concentrations with high-pressure liquid chromatography with ultraviolet detection. The limit of sensitivity was 5 $ng \cdot ml^{-1}$, and the coefficient of variation was 3.7% ± 2.5% at 120 $ng \cdot ml^{-1}$.

Uterine vascular resistance was calculated with the standard formula:

$$UVR = \frac{MABP - CVP}{UBF}$$

where UVR is uterine vascular resistance in dynes · sec · cm^{-5}, UBF is uterine blood flow in $ml \cdot min^{-1}$, MABP is mean maternal arterial blood pressure, and CVP is central venous pressure, both in millimeters of mercury.[5]

Changes in monitored and measured variables were evaluated for statistical significance with analysis of variance for repeated measures (Sheffé F test). A p value <0.05 was considered significant. All results are expressed as mean ± SE.

Results

Seven ewes at gestational ages ranging from 121 to 138 days were studied. The number of experiments performed for each infusion regimen was as follows: milrinone 1 $\mu g \cdot kg^{-1} \cdot min^{-1}$ (milrinone 1 μg), $n = 6$; milrinone 2 $\mu g \cdot kg^{-1} \cdot min^{-1}$ (milrinone 2 μg), $n = 8$; milrinone 4 $\mu g \cdot kg^{-1} \cdot min^{-1}$, (milrinone 4 μg), $n = 7$; dopamine 5 $\mu g \cdot kg^{-1} \cdot min^{-1}$ (dopamine 5 μg), $n = 6$; dopamine 10 $\mu g \cdot kg^{-1} \cdot min^{-1}$ (dopamine 10 μg), $n = 6$; and saline solution, $n = 5$. A saline solution study was followed by a milrinone study in three instances and by dopamine in the remaining two.

Ewes. The mean peak milrinone plasma concentration of 644 ± 45 $ng \cdot ml^{-1}$ occurred at the end of bolus injection (Fig. 1). After 60 minutes of milrinone 1 μg and milrinone 2 μg infusions, the plasma concentration declined to 117 ± 10 and 171 ± 9 $ng \cdot ml^{-1}$, respectively, and remained essentially unchanged thereafter.

The bolus injection of milrinone resulted in an increase in heart rate of approximately 50% (Table I). This tachycardia reverted to a normal heart rate after 30 minutes of milrinone 1 μg infusion but persisted for

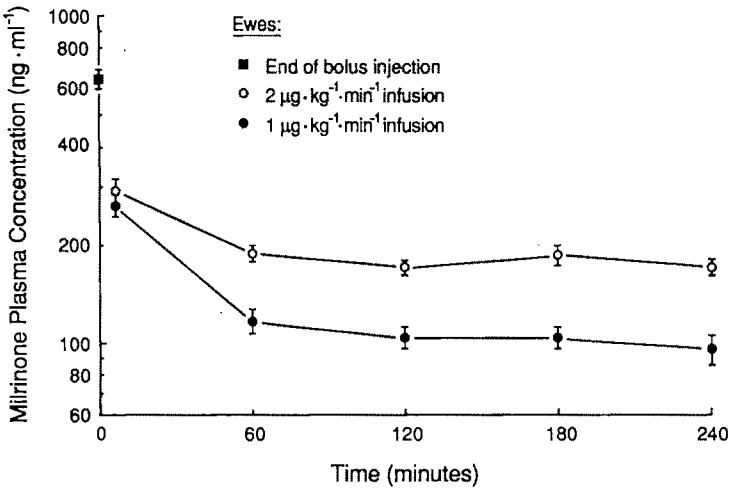

Fig. 1. Maternal plasma concentrations of milrinone (ng · ml^{-1}, mean ± SE) after bolus injection of 75 μg · kg^{-1} (time 0) and at 5, 60, 120, 180, and 240 minutes of infusion.

*Significantly different from control ($p < 0.05$).

up to 120 and 240 minutes in ewes given the milrinone 2 μg and milrinone 4 μg infusions, respectively. Dopamine 10 μg led to an approximately 20% increase in heart rate after 30 minutes of infusion, which was sustained up to the end of the study. No significant changes in heart rate were noted with the dopamine 5 μg infusion.

Milrinone 1 μg infusion did not result in any change in maternal blood pressure, whereas at 15 and 30 minutes of milrinone 2 μg infusion, there was a small but statistically significant reduction in mean arterial blood pressure from a control value of 93 ± 4 to 85 ± 3 mm Hg. A similar 10% decrease in mean arterial blood pressure at 15, 30 and 60 minutes seen with the highest milrinone infusion rate failed to reach statistical significance. No statistically significant changes in mean arterial pressure were noted with either dopamine infusion.

Intraamniotic and central venous pressures remained unchanged throughout all experiments. Control uterine blood flows were similar among groups; for example, saline solution, 356 ± 81 ml · min^{-1}; milrinone 1 μg, 344 ± 52 ml · min^{-1}; milrinone 2 μg, 307 ± 47 ml · min^{-1}; milrinone 4 μg, 312 ± 59 ml · min^{-1}; dopamine 5 μg, 396 ± 69 ml · min^{-1}; and dopamine 10 μg, 390 ± 67 ml · min^{-1}. Bolus injection of milrinone, as well as milrinone 1 μg infusion, resulted in no significant changes in uterine blood flow (Fig. 2). Milrinone 2 μg infusion led to increases in uterine blood flow of 13.9% ± 3.1%, 16.8% ± 3.8%, and 18.6% ± 3.4%, at 120, 180, and 240 minutes, respectively. With milrinone 4 μg infusion there was an 18.9% ± 7.4% increase in uterine blood flow at 180 minutes and a 22.3% ± 7.5% increase at 240 minutes. In contrast, dopamine administration caused a dose-related decrease in uterine blood flow between 15 and 60 minutes. At 60 minutes uterine blood flow was 15.0% ± 2.0% with dopamine 5 μg and 26.3% ± 6.5% with dopamine 10 μg (Fig. 2). Neither the bolus nor milrinone 1 μg infusion altered uterine vascular resistance, but milrinone 2 μg infusion resulted in a reduction in uterine vascular resistance ranging from 15% to 17% (Fig. 3). Changes in uterine vascular resistance seen with milrinone 4 μg infusion failed to

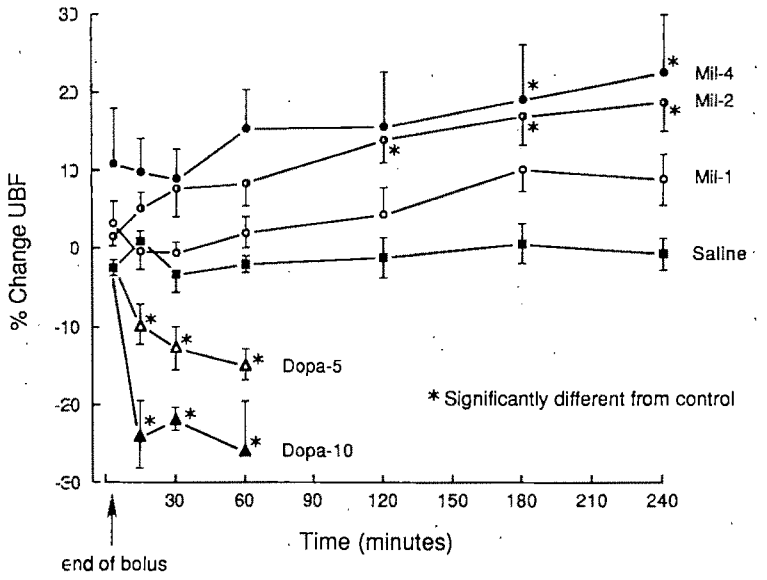

Fig. 2. Percent change (mean ± SE) in uterine blood flow *(UBF)* after bolus injection of 75 μg · kg^{-1} milrinone over 1 minute, at 15, 30, 60, 120, 180 and 240 minutes of milrinone infusion, and at 15, 30, and 60 minutes of dopamine infusion. *Mil-1,* Milrinone 1 μg; *Mil-2,* milrinone 2 μg; *Mil-4,* milrinone 4 μg; *Dopa-5,* dopamine 5 μg; *Dopa-10,* dopamine 10 μg.

reach statistical significance. A 25% to 40% increase in uterine vascular resistance was noted during dopamine 10 μg infusion.

Infusions of saline solution or milrinone did not affect maternal arterial pH or blood gas tensions at any time. In contrast, dopamine reduced maternal arterial pH at 15 and 60 minutes (Table II). Changes in arterial Po_2 were only significant with dopamine 5 μg at 15 minutes.

Fetuses. Milrinone could not be detected in any fetal plasma samples. Heart rate and mean arterial blood pressure were unaffected by infusions of saline solution, milrinone, or dopamine. Before infusion these values were: saline solution (n = 4), 166 ± 12 beats · min^{-1} and 46 ± 1 mm Hg; milrinone 1 μg (n = 6), 171 ± 6 beats · min^{-1} and 44 ± 2 mm Hg; milrinone 2 μg (n = 7), 165 ± 9 beats · min^{-1} and 42 ± 2 mm Hg; milrinone 4 μg (n = 6), 170 ± 6 beats · min^{-1} and 43 ± 2 mm Hg; dopamine 5 μg (n = 4), 156 ± 7 beats · min^{-1} and 42 ± 2 mm Hg; dopamine 10 μg (n = 4), 160 ± 11 beats · min^{-1} and 45 ± 5 mm Hg, respectively. Because of technical problems with the polygraph these variables could not be recorded in all experiments. Arterial blood pH and gas tensions, however, were determined in all fetuses and were found to be unaffected by infusions of saline solution, milrinone, and dopamine 5 μg. With dopamine 10 μg there was a progressive decrease in fetal arterial pH from 7.36 ± 0.02 to 7.30 ± 0.01 at 60 minutes and an increase in Pco_2 from 45 ± 3 to 50 ± 3 mm Hg at 15 minutes and 53 ± 3 mm Hg at 60 minutes (Table II).

Comment

These data suggest that milrinone produces no adverse effects in the pregnant ewe or fetus. At plasma concentrations considered to be therapeutic in humans, namely, 80 to 400 ng · ml^{-1},[9] the drug did not reduce uterine blood flow in pregnant ewes. On the contrary, at the two higher dosages, a small increase in uterine blood flow could be demonstrated after 2 to 4 hours of drug infusion. However, a potential limitation of measuring uterine artery blood flow is that it does not provide data on the relative placental and nonplacental perfusion.[11] Myometrial blood flow may be increased at the expense of placental perfusion by vasodilating agents, such as isoproterenol.[12] Further, the calculation of uterine vascular resistance with the use of values from a single vessel may not accurately reflect the vascular resistance throughout the uterus.

The uterine vascular bed is generally regarded to be maximally dilated at term of ovine pregnancy.[13] However, small increases in uterine blood flow have been found to occur in nonlaboring pregnant sheep given an agent with mild vasodilator activity, such as halothane.[14] Milrinone is also considered to be a mild vasodilator,[6, 7] and in the current study milrinone 2 μg infusion resulted in a decrease in uterine vascular resistance. Milrinone 4 μg infusion led to an increase in uterine blood flow of a magnitude similar to that of the intermediate dose but without the decrease in uterine vascular resistance achieving statistical significance. This was most probably due to insufficient power of statistical analysis (32%), because uterine vascular resistance could not be calculated in all milrinone 4 μg

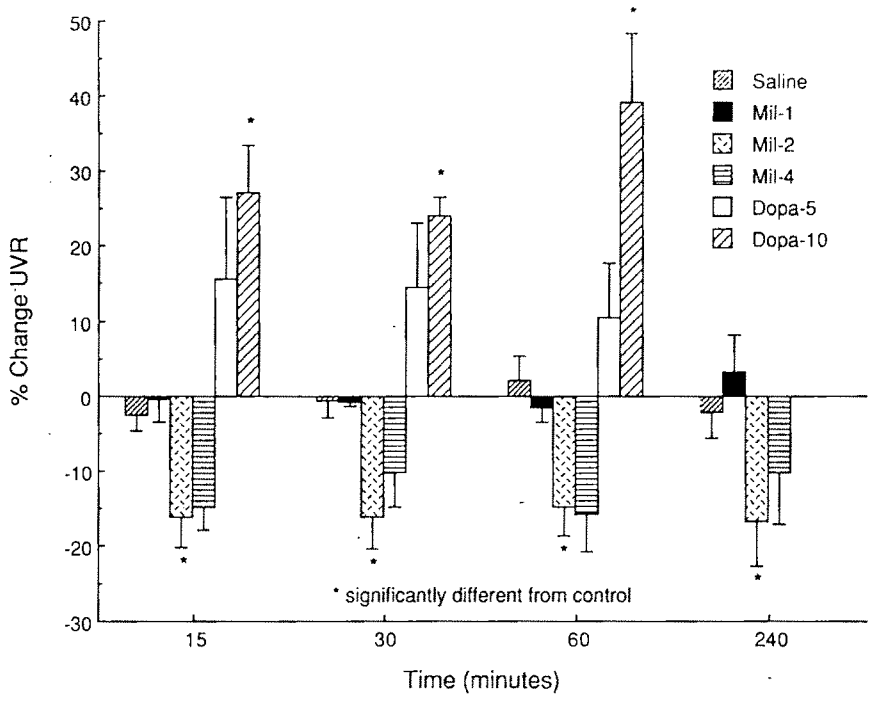

Fig. 3. Percent change (mean ± SE) in uterine vascular resistance *(UVR)* after 15, 30, 60, and 240 minutes of milrinone and 15, 30, and 60 minutes of dopamine infusion. *Mil-1,* Milrinone 1 μg; *Mil-2,* milrinone 2 μg; *Mil-4,* milrinone 4 μg; *Dopa-5,* dopamine 5 μg; *Dopa-10,* dopamine 10 μg.

studies. Furthermore, there also appears to be a ceiling to the cardiovascular effects of milrinone,[15] which may have been reached with milrinone 2 μg infusion. At the highest milrinone dose, drug-induced changes in uterine vascular resistance and uterine blood flow may have also been limited by maternal tachycardia and, possibly, reduced ventricular filling.

In contrast to milrinone, dopamine administration at two infusion rates used in clinical practice resulted in a dose-related decrease in uterine blood flow. Other investigators have also found dopamine to reduce uterine blood flow in normotensive and hypotensive pregnant ewes.[4, 5] This has been attributed to an increase in uterine vascular resistance, particularly at higher drug dosages.[5, 16] In this study dopamine 10 μg increased uterine vascular resistance by 45%. The reason for a reduction in uterine blood flow with dopamine 5 μg infusion is less clear because the increase in uterine vascular resistance did not achieve statistical significance. This could be related to the observation made by others that dopamine at lower dosages does not greatly affect uterine vascular resistance in sheep.[16] An increase in uterine tone caused by dopamine, which in itself may reduce uterine blood flow,[16] was not seen in any of our experiments and may be explained by the lower infusion rates of the drug used in our study.

An intravenous bolus injection of milrinone 75 $\mu g \cdot kg^{-1}$ resulted in significant maternal tachycardia. However, one should note that plasma concentrations of the drug after bolus administrations were well above the recommended therapeutic range.[9] High doses of milrinone have been shown to cause tachycardia with no additional improvement in hemodynamic status.[9, 17] Dopamine 10 μg infusion, which is an appropriate dose for clinical use, also resulted in moderate maternal tachycardia.

Table II. Values (mean ± SE) for maternal and fetal arterial pH and blood gas tensions (millimeters of mercury) before and after dopamine infusion

	0 min	*15 min*	*60 min*
Dopamine 5 μg			
Mothers			
pH	7.54 ± 0.02	7.48 ± 0.01*	7.46 ± 0.02*
P_{CO_2}	35 ± 2	37 ± 2	38 ± 2
P_{O_2}	96 ± 3	80 ± 2*	82 ± 6
Fetuses			
pH	7.35 ± 0.02	7.34 ± 0.02	7.33 ± 0.01
P_{CO_2}	44 ± 3	46 ± 2	47 ± 3
P_{O_2}	28 ± 1	27 ± 2	26 ± 2
Dopamine 10 μg			
Mothers			
pH	7.53 ± 0.01	7.46 ± 0.01*	7.46 ± 0.01*
P_{CO_2}	36 ± 1	40 ± 2	40 ± 2

P_{O_2}	25 ± 2	26 ± 2	26 ± 2

*Significantly different from control ($p < 0.05$).

Maternal arterial pH and blood gas tensions were unchanged during infusion of saline solution or milrinone, whereas administration of dopamine resulted in a significant reduction in arterial pH and a trend toward an increase in $PaCO_2$. It has been proposed that in sheep dopamine may cause pulmonary vasoconstriction and an increase in dead space ventilation.[4, 5, 18] A small decrease in PaO_2 has also been noted in these studies, but in the current one this occurred only in the dopamine 5 μg experiment.

The rate of milrinone 1 μg infusion was approximately 30% greater than the maximum recommended dose for human use.[9] Nonetheless, it resulted in plasma drug concentrations corresponding to the lower limit of the therapeutic range in man. The greater drug requirement in pregnant sheep may be related not only to species differences but also to gestational changes in blood volume, its constituents, and cardiac output.[19-22] Pregnancy has been shown to alter the pharmacokinetics of several drugs.[23] We are unaware of any reports on the effects of pregnancy on milrinone disposition.

It is of interest that even with the use of a very sensitive analytic technique, milrinone could not be detected in fetal plasma at any time during the study. This could be due to a slow rate of placental diffusion and possibly to placental degradation of milrinone, which has an amine structure.[8] The ovine placenta is syndesmochorial while that in humans is hemochorial; therefore the lack of placental transmission might not apply to pregnant women.

Dopamine did not affect fetal heart rate or mean arterial blood pressure. However, with dopamine 10 μg infusion the fetus demonstrated significant arterial acidemia. It would be tempting to assume that this was related to the approximately 25% reduction in uterine blood flow observed with dopamine infusion, but others have shown that ovine uterine blood flow may be decreased by as much as 50% without causing fetal asphyxia.[13] Thus maternal acid-base derangement was the most likely cause of fetal acidemia noted in the dopamine 10 μg experiments.

In conclusion, our data suggest that milrinone does not have adverse effects on uterine blood flow and fetal well-being when administered to pregnant sheep. The clinical relevance of these data is limited by the fact that they were obtained in healthy, normotensive animals and thus may not apply to pregnant women with impaired cardiovascular performance. Obviously, careful clinical trials of milrinone would first be required to ascertain its safety and efficacy during human pregnancy.

LETTERS TO THE EDITORS

Periconceptional exposure to topical 5-fluorouracil

To the Editors: The recent article by Odom et al. (Odom LD, Plouffe L Jr, Butler WJ. 5-Fluorouracil exposure during the period of conception: report on two cases. AM J OBSTET GYNECOL 1990;163:76-7) calls to attention the theory that periconceptional exposure to topical vaginal 5-fluorouracil (5-FU) may be on the rise and speculates about two successful pregnancies exposed to 5-FU.

During 1990 we counseled seven patients referred for risk assessment because of periconceptional exposure to intravaginal topical 5-FU during treatment of human papillomavirus lesions. The patients were informed that, although it is suspected that 5-FU is a teratogenic agent, there is no information available about its vaginal topical use. However, on the basis of the all-or-none response we thought that the situation probably did not pose a significant risk. Of these patients, five have already been delivered of their infants. Four infants were normal; one 26-year-old woman gave birth to a female infant with Down syndrome (47,XX,+21 karyotype). Studies to determine the parental origin and meiosis stage of the nondisjunction event were not successful.

It is known that teratogenic effects have been produced with 5-FU in all animal species tested[1] and that there is evidence to suggest teratogenicity in humans. A different hypothesis could explain a potential association between periconceptional exposure to an antineoplastic and occurrence of chromosomal abnormalities.[2-4] It seems appropriate to be very cautious about speculating as to possible conclusions. Thus it does not seem that two negative cases (no teratogenic effects) can support the final statement of the article by Odom et al.: "It is likely that an uneventful ongoing pregnancy after periconceptional exposure will not display any adverse effects." If, for instance, periconceptional exposure of 5-FU would increase the incidence of birth defects three times from, say, 3% to 9%, it would be necessary to monitor at least 85 cases to detect this hypothetical increment with 95% confidence. A teratogenic effect could exert its action not by increasing the overall rate of birth defects but by producing a selective increment of birth defects (remember the thalidomide and diethylstilbestrol experiences).[5, 6] Furthermore, recent studies have suggested that to appeal to the concept of all-or-none effect could be an oversimplification.[7]

Thus much more information is necessary to assess potential risks of human developmental toxicity associated with the use of vaginal topical 5-FU.

Reply

To the Editors: We appreciate the comments of Otaño et al. Our report was written in the context of two previous communications that depicted dire results from 5-FU exposure during pregnancy.[1,2] We could not find any report of a healthy pregnancy outcome. The patients referred to our center had been so advised by their physicians. Both patients considered early pregnancy termination in light of such a poor prognosis.

We shared the little and very concerning literature with our patients and, as is outlined in our article, monitored them closely. One patient accepted amniocentesis, and both patients underwent ultrasonographic targeted imaging to identify any suggestion of fetal malformation. Both infants were healthy. In this context, we felt it important to report these two cases to add balance to the published reports.

Periconceptual exposure to 5-FU in the United States appears to be a relatively rare event. In our two genetic centers we have not seen any other case to date. We know of five other cases, all of which have resulted in healthy pregnancies (Butler WJ. Personal communication). The letter from Otaño et al. adds important information to this field and again emphasizes the fact that healthy infants may result from these instances of periconceptual 5-FU exposure. We hope Otaño et al. publish their data in a full paper in the near future. We also hope that all cases of 5-FU exposure during pregnancy will be reported and recorded so the data can be compiled and analyzed.

It was clearly not our intention to suggest that periconceptual 5-FU exposure was an insignificant event. In view of the adverse outcomes reported to that point, we simply wanted to report two healthy births. The most important step in this issue is to prevent such events from occurring in the first place by ensuring that patients not get pregnant during exposure cycles. In those cases in which exposure occurs we advocate close monitoring via early fetal imaging with high-resolution vaginal ultrasonography and discussion with the patients as to the indications for fetal chromosomal

studies. We feel this approach is desirable at this time given the lack of solid data on this complex issue.

Criteria for the diagnosis of infertility

To the Editors: We read with great interest the article by Aitken et al. (Aitken RJ, Irvine DS, Wu FC. Prospective analysis of sperm-oocyte fusion and reactive oxygen species generation as criteria for the diagnosis of infertility. AM J OBSTET GYNECOL 1991;164:542-51). We believe it presents an exciting data set that provides clear evidence of the validity of the assessment of sperm-oocyte fusion and reactive oxygen species generation in the assessment of male fertility when conventional semen analysis is of no prognostic value.

Recently published data by Aitken and West[1] and by us[2] have put forward the concept of the contribution of seminal leukocytes to the levels of reactive oxygen species detected in semen. In view of those data and because the procedure used to prepare the semen samples (centrifugation three times) in the study of Aitken et al. yields varying numbers of these seminal elements, which are present in almost every semen sample,[3] we believe that an important question should be addressed. Have the authors screened the examined semen samples for leukocyte numbers and types? If available, these data will shed new light on the role of seminal leukocytes on the function of spermatozoa and subsequent fertility. Furthermore, such information will help decide the therapeutic approach to treat men with reactive oxygen species–related infertility. Because evidence from in vitro experiments supports the inhibition of reactive oxygen species–induced lipid peroxidation,[4] in vivo treatment with this antioxidant in cases of spermatozoa-derived reactive oxygen species might be beneficial. However, if leukocytes are the main source of reactive oxygen species, treatment with antibiotics might be more appropriate.

Reply

To the Editors: I am grateful to Kessopoulou et al. for their interest in our studies on the diagnostic significance of the hamster oocyte penetration test and measurements of reactive oxygen species in cases of male infertility. I fully concur that the therapeutic implications of the reactive oxygen species data will be influenced by a knowledge of the source of the reactive oxygen species, although there are limitations to the value of this information.

Within the data set described in our article we found no significant relationships between the presence of round cells in the washed ejaculate and the level of reactive oxygen species production. However, we did not definitively identify or type the leukocyte populations in these samples with the immunocytochemical techniques described in our recent publication.[1] Where such techniques have been applied,[2] we showed that all human semen samples contained leukocytes and that the low levels of reactive oxygen species production observed in the normal fertile population were highly correlated with the concentration of these cells. Within our semen donor panel we have even found a case in which normal fertility was apparently compatible with high levels of reactive oxygen species production associated with concentrations of seminal leukocytes that were tenfold higher than the 1×10^6/ml threshold of normality suggested by the World Health Organization (1987). Such a situation could arise if activated leukocytes only enter the seminal fluid at the moment of ejaculation (from the seminal vesicles or prostate gland, for example), in which case the reactive oxygen species generated by the leukocyte population would not damage the spermatozoa because the spermatozoa would be protected by the antioxidant properties of seminal plasma.[3] Conversely, if activated leukocytes enter the male reproductive tract at a more proximal site, such as the rete testes or epididymis, the opportunity for inducing peroxidative damage in spermatozoa would certainly exist. In other words, the clinical interpretation of leukocytospermia is not straightforward; it is confounded by a number of factors, including the site of infiltration, the leukocyte species involved, and the nature and kinetics of their activation, none of which can be ascertained by simple leukocyte counts.

Furthermore, generation of reactive oxygen species by leukocytes should not be confused with generation of reactive oxygen species by spermatozoa, which is highly correlated with the appearance of defective sperm function.[4, 5] Therefore I reinforce the recommendation by Kessopoulou et al. that in cases of elevated reactive oxygen species production the source of

the oxidative stress be identified to differentiate cases involving leukocytic infiltration from those associated with a defect at the level of the germ cell. A protocol for achieving this distinction is in press.[2]

Anticancer drugs during pregnancy: Are we able to discard them?

To the Editors: We read with interest the article by van der Zee et al. (van der Zee AGJ, de Bruijn HWA, Bouma J, Aalders JG, Oosterhuis JW, de Vries EGE. Endodermal sinus tumor of the ovary during pregnancy: A case report. Am J Obstet Gynecol 1991;164:504-6). They treated a patient with endodermal sinus tumor surgically and without chemotherapy during pregnancy. She received a cisplatin-containing regimen after delivery. van der Zee et al. stated the potential risks of cisplatin during pregnancy and the well-known efficacy of cisplatin-containing regimens. However, chemotherapy other than cisplatin can be used in this well-known malignant germ cell tumor during pregnancy.

The potential risks of cisplatin are already well described, which was why we used vincristine, actinomycin D, and cyclophosphamide (VAC) instead of cisplatin-containing regimens during pregnancy in a recent case report.[1] In the case we reported, the patient had received conservative surgery and six courses of VAC combination chemotherapy from 16 weeks' gestation and was delivered of a normal infant at 37 weeks' gestation. After delivery we replaced the VAC protocol with a vinblastine, bleomycin, and cisplatin protocol. Two courses of this cisplatin-containing regimen were used. The patient and her child are doing well >5 years after treatment.

Endodermal sinus tumor of the ovary appears to be almost uniformly fatal; most authors report patient survival with a 2- or 3-year survival rate rather than a 5-year survival rate. Although van der Zee et al. believe cisplatin-containing regimens improve the prognosis of endodermal sinus tumor, the usefulness of VAC is not fully discarded. The promising results achieved with VAC were confirmed by others, at least in patients with early stage disease.[2]

van der Zee et al. avoided giving chemotherapy during pregnancy; however, there are numerous reports concerning micrometastasis in early stages of ovarian cancers. Although we do not know whether the endodermal sinus tumor propagates or remits during pregnancy, who is responsible for advancement of the disease if there are lymph node metastases or if invisible masses remain after surgery? Can we ignore the possibility of metastasis during pregnancy?

There is a therapeutic dilemma for the pregnant patient in whom is found a malignancy that requires chemotherapy. As yet chemotherapy in the second and third trimesters has not resulted in teratogenicity.[1] We believe it to be necessary to use non-cisplatin-containing regimens of chemotherapy during pregnancy, at least in this highly malignant tumor of the ovary.

Reply

To the Editors: We thank Kim et al. for their interest in our case report. We agree that an unexpectedly low incidence of teratogenesis is associated with the use of anticancer agents in pregnancy, especially when used in the second and third trimesters. However, the experience is limited: The literature consists mainly of case reports (mostly successful); hardly any information is available to determine the long-term risks of in utero exposure to chemotherapy.[1,2] In an overview of adult cancer survivors, Loescher et al.[3] described a higher risk of second malignancies in patients after receiving chemotherapeutic agents. This higher risk is especially the case after alkylating agents, such as cyclophosphamide, which was used by Kim et al. So far no comparable data are available to determine long-term effects for individuals who have been exposed to chemotherapy in utero. Kim et al. are concerned about metastases of endodermal sinus tumor to the fetus. However, to date only seven documented cases of fetal metastases of other malignancies have been described.[1] Considering these data, the risk for fetal metastases seems to be very low and is hardly an argument for starting chemotherapy during pregnancy. The maternal serum α-fetoprotein is a sensitive and well-established marker in endodermal sinus tumor. Weekly measurement of the maternal serum α-fetoprotein enabled us to detect

the recurrence of endodermal sinus tumor at an early stage. We awaited further maturation of the child until caesarean section was done in the 33rd week of gestation. Kim et al. chose to treat their patient during pregnancy with a regimen of vincristine, actinomycin D, and cyclophosphamide (VAC) to avoid the use of cisplatin during pregnancy. In a recent review Nash and Young[4] stated that, although only randomized prospective trials can definitively establish survival advantages between the VAC and PVB (cisplatin, vincristine, and bleomycin) regimens, the cumulative experience from the existing literature seems to indicate that PVB is a more active regimen.[4,5] These authors tend to prefer the BEP (cisplatin, etoposide, and bleomycin) regimen, which we used in our patient, because the results are comparable to those of PVB but with less long-term toxicity.[4] We were fully aware of a high risk of recurrence of the endodermal sinus tumor after surgical resection without adjuvant chemotherapy. However, the availability of cisplatin-containing regimens with well-known high efficacy, which result in survival rates of 96% in stages I and II and 79% in stages III and IV, enabled us to postpone chemotherapy until after the delivery of the child.[4] We were able to treat the mother with the chemotherapeutic regimen with the highest efficacy and to omit unknown potential carcinogenic damage to the fetus. To date, the mother and her 4-year-old child are doing well.

Benefits of cesarean section stapling device understated?

To the Editors: I read the article by Villeneuve et al. (Villeneuve MG, Khalifé S, Marcoux S, Blanchet P. Surgical staples in cesarean section: A randomized controlled trial. Am J Obstet Gynecol 1990;163:1641-6) with interest. However, a few points need further clarification. Although the instrument depicted in Fig. 1 is the device used in their study, it is no longer available in Canada and has never been available in the United States. Also, although Dr. Gilles Monif is a well-respected member of the obstetrics and gynecology community specializing in the treatment of infectious disease, his criteria for morbidity are not universally known, and a reference or description of his criteria for endometritis would be helpful.

The study is an excellent investigation in the use of the Auto Suture Poly CS* 57 disposable surgical stapler. Although minor questions arise, such as the length of experience of the instrument's users, the study confirms the findings of earlier reports.[1-4] However, the conclusions of Villeneuve et al. are not substantiated by or consistent with their own and previously reported data. Their conclusions are perhaps different because of their failure to recognize that their population may represent a specific subset of the cesarean section population in North America. Their results do not contradict those of Burkett et al. because the patient populations had several differences: Burkett et al. found a significant decrease in infectious morbidity presumably caused by their higher baseline postoperative infection rate. The decrease in postoperative infection with the use of the cesarean section stapler was significant and led to considerable cost savings. The population of Villeneuve et al. does not have a high infection rate; therefore it would take a larger number of patients to demonstrate significant benefit. However, the decrease in blood loss in the study of Villeneuve et al. was significant; I disagree with their conclusion that significant savings of blood is not beneficial. Similar studies have been performed in a low-risk infectious population, and similar significant decreases in blood loss were found.[1,3] This decrease in blood in the operative field was of major benefit to the operating physicians, turning a usually bloody procedure into a safer and easier procedure for the surgeon. The significant decreases in blood loss are also beneficial to the patient in light of the decreased but ever-present risk of transfusion-related human immunodeficiency virus and other infectious exposure. Other studies in high-risk infectious populations have demonstrated >60% decrease in postoperative infection rates with the surgical stapling device in high-risk populations similar to those studied by Burkett et al.

As mentioned by Villeneuve et al. the retaining pin had the potential for causing vessel puncture, and it has been removed in the new Food and Drug Administration–approved Auto Suture Poly CS 57 instrument. Therefore, although I thought the study of Villeneuve et al. was well done, I do not agree with their conclusion that significant decreases in blood loss are not important enough to give the instrument further consideration. Their patient population was at low risk for postoperative infections; therefore their sample size

*Reg. U.S. Patent and Trademark Office. Auto Suture Company, Division of United States Surgical Corporation, Norwalk, Conn.

was not large enough to allow them to make comments regarding the instrument's role in reducing post–cesarean section infections. Thus the question of the utility of the Auto Suture Poly CS 57 disposable uterine device still deserves further attention.

The uterine stapling device for cesarean section: A positive view

To the Editors: In their study comparing the Auto Suture Poly CS 57 disposable uterine stapler with the standard hysterotomy for cesarean section, Villeneuve et al. did not find reductions in operating time, risk of febrile morbidity, or length of postoperative hospital stay in the group of patients in whom the uterine stapler was used. In addition they considered that the difference in blood loss between both groups was small and of questionable clinical significance and that their results do not support the routine use of the Auto Suture Poly CS 57 in low transverse cesarean sections.

I would like to comment on this article. The authors state that theirs is the first randomized study comparing the uterine stapling device with the standard suture technique for cesarean deliveries in human beings. They also mention that only one previous study, which was not a randomized controlled trial,[2] had evaluated the Auto Suture Poly CS 57. Their statement is inaccurate. Human studies evaluating the staple device have appeared since 1988; several are randomized controlled trials.[3] All investigators found the uterine stapler principle to be unquestionably sound, and no comparative series provided an overall statistically superior result in the traditional suturing technique when compared with the uterine stapler.

On the basis of the available clinical data it can be concluded that the benefits of the absorbable uterine stapler depend on surgical experience and patient population. Significant reductions in blood loss and operating time can be expected in the more experienced surgeons who are familiar with the device. In high-risk obstetric patients the instrument produces a significant decrease in the rate of febrile morbidity, resulting in a shorter hospital stay and a substantial savings in hospital costs. The socioeconomic characteristics and obstetric risk factors of the study conducted by Villeneuve et al. were not stated in their article.

It is difficult to understand the authors' high failure rate regarding the correct application of the uterine stapler (45.5%) and their high incidence of accidental extensions (42%) and associated significant bleeding (62%), which obviously stems from their incapability of completely applying the stapler. Failure to use the entire length of the stapler cartridge will result in an incision smaller than the required 11.5 cm. In light of this, their estimated total blood loss in the cases of the study is inaccurate because no differentiation in volume of blood loss can be made between that of the uterine edges where the staples were applied and of the traumatic uterine wall bleeding.

In my experience with >100 cases, a learning curve of 3 to 6 cases seems necessary to maximally use the stapling device.[4]

I concur with the author's conclusion that it is probably premature to recommend routine use of the uterine stapler for every cesarean section. Nevertheless, on the basis of current information, its use should be strongly recommended for obstetric patients in whom the expectation of blood loss during the cesarean section is greater than average, the amount of intraoperative blood loss is critical, or the risk of postoperative infectious morbidity is high.

To the Editors: Thank you for this opportunity to clarify some aspects of our randomized clinical trial on the Auto Suture Poly CS 57 staples used in cesarean sections.

We considered febrile morbidity to be present when at least one of the following conditions was satisfied[1]: (1) fever ≥38° C on two consecutive occasions ≥4 hours apart, with the second reading ≥0.2° C higher than the first; (2) fever ≥38.5° C on one occasion; or (3) fever ≥38° C on three occasions in any 24-hour period.

We do not think our conclusions would have been different had our experience with the instrument been longer. Data were reanalyzed for the first (period 1) and last (period 2) 100 patients enrolled in the study separately (Table I). Results are largely similar for the two periods. In period 2, when obstetricians had gained

Table I. Blood loss and operating time according to hysterectomy procedure, stratified for study period

	Period 1		*Period 2*	
	Stapling device	*Standard hysterotomy*	*Stapling device*	*Standard hysterotomy*
Blood loss				
Total blood loss (ml, mean ± SEM)	517 ± 33	568 ± 59	466 ± 35	588 ± 48
Blood loss caused by hysterotomy (ml, mean ± SEM)	275 ± 29	337 ± 51	203 ± 26	253 ± 32
Hemoglobin deficit (gm/dl, mean ± SEM)	1.06 ± 0.1	1.23 ± 0.1	1.25 ± 0.2	1.24 ± 0.2
Operating time (min, mean ± SEM)				
From uterine incision to closure of hysterotomy	13.1 ± 0.6	11.3 ± 0.7	12.4 ± 0.6	13.0 ± 0.7
From abdominal incision to closure of the wound	41.3 ± 1.6	38.0 ± 1.7	43.7 ± 1.9	40.2 ± 1.6

experience with the stapler, the reduction in total blood loss with the stapler was still minimal (122 ml), and no difference emerged in the hemoglobin deficit. Moreover, the use of the stapler did not substantially reduce the operating time.

We agree that significant savings of blood are beneficial for the patients. However, the magnitude of the difference we observed in total blood loss was small, and the hemoglobin deficit was similar in the two groups. Therefore we feel that the small differences observed in estimated blood loss had limited clinical significance.

We did not observe a beneficial effect of the instrument on the incidence of endometritis. Given the low baseline incidence of this complication in our study population, we agree that such an effect would be statistically difficult to detect. In our view the use of the stapling device with the main objective of reducing the number of women with endometritis does not seem warranted in a population in which the baseline frequency of endometritis is as low as in ours.

We are pleased that the retaining pin in the stapler we tested was subsequently removed. This pin complicated the surgery in six of our patients. The removal of the pin is certainly an improvement over the original instrument.

The short umbilical cord

To the Editors: A short umbilical cord can predispose a fetus to distress, rupture of the umbilical cord, premature placental separation, failure of the presenting part to descend, and primarily uterine inversion. A short cord with a vas insertion is a rare and deadly combination. In 1750 Smellie[1] described a fetal death caused by a short cord. DeLee[2] summarized short cord literature and established a length of 25 cm and fundal cord insertion as an absolute definition. Gardiner[3] attempted to redefine a short umbilical cord as ≤32 cm in length. Rosen[4] reviewed the literature of his day and found the incidence of a short umbilical cord to be between 0.78% and 0.43%. He distinguished between the absolutely short umbilical cord (an average of <30 cm) and the relatively short umbilical cord (attributed to cord entanglement). The potential danger of such umbilical cord presentations remains in question. Rosen concludes that stillbirth is not increased in the absolutely short cord group versus the control group. Recently Sørnes attempted to evaluate short cord effects on delivery and believed it to be "hazardous for the infant."[5] He concludes that "two thirds of the babies with cords less than 35 cm length were born nonoperatively and this is unexplained."

The explanation is provided by Brickner: "the placental location and placental umbilical cord insertion must be considered"[6] when studying short cords. When a placenta is low lying and has a battledore insertion of the umbilical cord near the cervix, a 20 cm umbilical cord is ample for delivery of the infant to the umbilicus. A short cord can be suspected if the placenta is known to be fundally located and the umbilical cord is inserted centrally, creating the longest length necessary to deliver. With a floating presenting part and failure of descent during labor combined with possible signs of fetal distress, a potential short cord complication can be avoided.

Crown-rump length dating of pregnancy at less than nine weeks' gestation

To the Editors: I have used the following formula for the last 7 years to date intrauterine pregnancy at <9 weeks' gestation by using crown-rump length when embryonic cardiac activity is present: Mean gestational age (menstrual age) in days = 40 + The crown-rump length in millimeters (e.g., 9 mm crown-rump length = 49 days or a 7-week embryo). This formula suggests that there is linear growth of the embryo (about 1 mm per day) until 9 weeks of gestation or until the embryo is approximately 25 mm or 1 inch in length. The 95% confidence limits are ±4 days assuming the pregnancy is normal and the crown-rump length measurement is accurate.

First successful cesarean section in the British empire

To the Editors: Gabert and Bey[1] recently reviewed the history and development of cesarean section in an interesting and informative manner. One such operation that has escaped general attention, however, involves a legendary figure of nineteenth-century medicine.

James Miranda Stuart Barry (1795-1865) entered Edinburgh University in 1809 and qualified as a doctor of medicine in 1812.[2-4] Because Barry completed the requirements at an early age, the senate of the university refused to admit him to the degree until political pressure was brought to bear.

On July 5, 1813, Barry entered the British army as a medical assistant over the objection of the principal medical officer. In 1815, after he had been posted to the Cape of Good Hope, his skill as a physician was soon recognized and he was frequently sought as an obstetrician.

Sometime between 1815 and 1821, Barry performed a cesarean section on a patient named Mrs. Munnik. It is not known why the cesarean was required. Both mother and child, James Barry Munnik, survived the operation. A grandson of this child, James Barry Munnik Hertzog (1866-1942), later became the prime minister of South Africa from 1924 through 1939.

Barry learned about obstetrics from a course at Edinburgh given by James Hamilton (1767-1839), professor of midwifery at the university and the acknowledged leader in obstetrics in Scotland. Although midwifery was not required for graduation, Hamilton's course and teaching sessions at the hospital were always crowded.[5] Hamilton performed two cesarean sections but had fatal results in both instances.

When Barry died in London in 1865 it was discovered that she was a woman. From 1809 to 1865 she had successfully masqueraded as a man. She is now recognized as the first British woman physician and the first physician of either sex in the British empire to perform a cesarean section in which both the mother and the child survived.

The first successful operation in America was performed by Jesse Bennett on his wife in 1794.[6] King[7] maintains that the honor belongs to Richmond, who operated in 1827. Gabert and Bey[1] support Richmond's claim; therefore some question still exists about who was first. Incidentally, Richmond was forced to sacrifice the child to save the mother. Barry's section took place between Bennett's and Richmond's.

Two other reports of operations in this period deserve passing comments. Naqui,[8] contending that Barlow performed a successful operation in 1793, is in error because although the mother was saved the child was dead. In 1834 Greaves[9] saved both mother and child. The operation of Barry clearly preceded that of Greaves.

The power of the inevitable

The health care crisis in this country makes change inevitable. There is one organization that recognized this fact nearly 50 years ago. Group Health Cooperative is the largest consumer-governed HMO in the country. Our medical staff is self-managed and sets its own practices and guidelines. We can offer financial security, strong collegial relationships, continuing education, and, most importantly, diverse practice opportunities designed to fit the individual's practice style, needs and desires.

Feel for yourself the power of the inevitable. For further information about becoming a Group Health OB/GYN, call (800) 543-9323. Group Health is an equal opportunity employer.

Practice Where Your Skills Are Needed Most—Northwestern New Mexico-NorthEastern Arizona

The Navajo Indian Health Service offers professional challenge in a relaxed culture, for BC/BE OB/GYN's at its Shiprock, Tuba city, Chinle, and Gallup hosptial to start July, 1992. Join an academically strong, progressive group of recently trained Ob/Gyn's working with 4-6 CNM's. Our hospitals are well equipped and staffed with a full range of specialities. We are proud of our ability to provide quality care to an underserved rural population of Native American women. Our location and working schedule offer plenty of opportunity for outdoor recreation in the magnificent four corners region of the American Southwest. Skiing the southern Colorado rockies; hiking the Grand Canyon; roaming the Utah, New Mexico, Colorado, and Arizona wilderness areas; rafting the San Juan and Colorado rivers are just a few of the recreational activities in our backyard. All our facilities are fully JCAHO accredited. Long or short-term opportunities are available. We offer a gorgeous Southwest setting, a laid-back rural lifestyle, and a terrific spirit of comradery. We pay Civil Service or Commissioned Corps salaries and benefits include paid malpractice, paid CME, moving expenses, education and training loan repayments of up to $35,000 per year. And a good time! U.S. Citizenship or permanent VISA required. Call or write: Physician Recruitment Office, Navajo Area Indian Health Service, P.O. Box G, Window Rock, Arizona 86515, 800/221-5646 or 602/871-4811 or Alan G. Waxman, M.D., Department of Obstetrics and Gynecology, Gallup Indian Medical Center, P.O. Box 1337, Gallup, New Mexico 87301, 505/722-1000.

An Equal Opportunity Employer. Preference in filling positions given to qualified Indian candidates in accordance with the Indian Preference Act.

Director of Perinatology

Due to expansion of the scope of the oldest and most prestigious family practice residency program in the south, we are seeking a BE/BC Perinatologist for the faculty/staff. With 36 residents, this progressive program's philosophy is to provide solid training in obstetrics. The position will be multi-faceted with aspects of patient care, teaching, and private consultation, and carries the opportunity for an academic affiliation with the Medical College of Georgia. There is a dedicated antenatal testing unit. The hospital is a 417-bed tertiary care facility with Level III NICU and 2 BC Neonatologists. Approximately 4000 births are facilitated each year, with 10% deemed high risk. Enjoy the luxury of excelling in your area of expertise with good call coverage from a large group of obstetricians who handle high risk patients as part of their daily practice. Highly competitive compensation package is offered. Just 90 minutes from Atlanta, this is the second largest city in Georgia, with a population of 250,000 and a 38 county referral base. An Equal Opportunity Employer M/F

Beth Israel Hospital Boston

This established physician practice is offering an excellent opportunity for a BC/BE obstetrician. We're located in beautiful Southeastern New Hampshire, where you'll discover the ideal lifestyle. The location offers proximity to mountains, lakes and seacoast, plus a wealth of cultural attractions. It all adds up to a very healthy family environment.

We're offering a competitive salary, and occurrence malpractice premiums are fully paid. What's more, there's an ownership opportunity after the initial employment period. The position will be available by July, 1992 or earlier.

This position has a lot to offer. In a state that has everything.

The practice is affiliated with a 330-bed hospital with a Level II Nursery in one of scenic New England's fastest-growing areas, just one hour from Boston.

Reply with CV to: Department of Physician Services, Catholic Medical Center, 100 McGregor Street, Manchester, NH 03102. (603) 626-2879. This could be everything you always wanted.

THE DEPARTMENT OF OBSTETRICS AND GYNECOLOGY UNIVERSITY OF PITTSBURGH SCHOOL OF MEDICINE

The Department of Obstetrics and Gynecology at the University of Pittsburgh is seeking a full-time faculty member to serve as Director for Research in Reproductive Sciences.

Applicants must be Board-Certified in Obstetrics and Gynecology and must have demonstrated experience in basic science laboratory research and administrative experience with collaborative research programs.

Academic rank and salary will be commensurate with experience, training and achievements.

Send inquiry and curriculum vitae to:

Richard L. Sweet, M.D.
Professor and Chairman
Department of Obstetrics and Gynecology
University of Pittsburgh School of Medicine
c/o Magee-Women's Hospital
300 Halket Street
Pittsburgh, PA 15213

The University of Pittsburgh is an equal opportunity, affirmative action employer.

THE DEPARTMENT OF OBSTETRICS AND GYNECOLOGY UNIVERSITY OF PITTSBURGH SCHOOL OF MEDICINE

The Department of Obstetrics and Gynecology at the University of Pittsburgh is seeking a full-time faculty member to serve as Director of House Staff Affairs and Medical Student Education.

Applicants must be Board-Certified in Obstetrics and Gynecology, and must have experience directing house officer training and medical student clerkships.

Academic rank and salary will be commensurate with experience, training and achievements.

Send inquiry and curriculum vitae to:

Richard L. Sweet, M.D.
Professor and Chairman
Department of Obstetrics and Gynecology
University of Pittsburgh School of Medicine
c/o Magee-Women's Hospital
300 Halket Street
Pittsburgh, PA 15213

The University of Pittsburgh is an equal opportunity, affirmative action employer.

OB/GYN
FLAGSTAFF, ARIZONA

Enjoy sharing the challenge of an Obstetrics and Gynecology practice with two Perinatologists, Certified Nurse Midwives and a Certified Nurse Practitioner, while living where most people vacation. We desire a Board Certified or Board Eligible OB/GYN surgeon. A modest call schedule and comfortable benefits are a part of our offer. We have a positive, patient oriented staff. Northern Arizona is a great place to raise a family. Please send letter of interest and Curriculum Vitae to:

Perinatal Associates
of Northern Arizona
ATTN: Ritamarie Lesauski
77 West Forest, Suite 205
Flagstaff, AZ 86001

or call (602) 773-2552

NORTHERN CALIFORNIA

The Permanente Medical Group, a growing multispecialty group, is recruiting physicians in a variety of specialties for positions throughout our beautiful Northern California region: the San Francisco Bay Area, Sacramento and the Central Valley.

Obstetrician/Gynecologist

BC/BE Obstetrician/Gynecologist sought to join small congenial clinic setting within established pre-paid multispecialty group. Practice consists of general obstetrics and gynecology, high risk obstetrics and infertility. Expertise in colposcopy, laparoscopy, hysteroscopy and laser are welcomed. Association with resident staff and teaching opportunities available.

Kaiser Permanente offers competitive salaries and excellent benefits including full coverage malpractice insurance, medical, dental and group life insurance, vacation, educational leave and an excellent retirement program.

For more information, send CV to: Victor David, M.D., Chief, Obstetrics and Gynecology, The Permanente Medical Group, 901 Nevin Avenue, Richmond, CA 94801. EOE

KAISER PERMANENTE
Good People. Good Medicine.

HAMAD MEDICAL CORPORATION
DOHA, QATAR

Hamad Medical Corporation is a 1,065 bed referral facility with 4,100 staff and is the main health establishment in the country with its modern equipped facilities, is seeking for a well experienced Embryologist to supervise the I.V.P. Laboratory.

The required candidate must hold a minimum of B.Sc. in the relevant specialities and at least 4 years experience as an Embryologist.

Salary is according to experience.

Send complete CVs, copies of certificates with contact telephone number / address and attach one recent photograph to:

21- and 28-day regimens

ORTHO-NOVUM 777 Tablets

TRADEMARK

norethindrone/ethinyl estradiol

Each white tablet contains 0.5 mg norethindrone and 0.035 mg ethinyl estradiol. Each light peach tablet contains 0.75 mg norethindrone and 0.035 mg ethinyl estradiol. Each peach tablet contains 1 mg norethindrone and 0.035 mg ethinyl estradiol. Each green tablet in 28-day regimen contains inert ingredients.

IMPORTANT NOTE—This information is a BRIEF SUMMARY of the complete prescribing information provided with the product and therefore should not be used as the basis for prescribing the product. This summary was prepared by deleting from the complete prescribing information certain text, tables and references. The physician should be thoroughly familiar with the complete prescribing information before prescribing the product.

INDICATIONS AND USAGE: PREVENTION OF PREGNANCY.

CONTRAINDICATIONS: Oral contraceptives should not be used in women who currently have the following conditions: 1. Thrombophlebitis or thromboembolic disorders. 2. A past history of deep vein thrombophlebitis or thromboembolic disorders. 3. Cerebral vascular or coronary artery disease. 4. Known or suspected carcinoma of the breast. 5. Carcinoma of the endometrium or other known or suspected estrogen-dependent neoplasia. 6. Undiagnosed abnormal genital bleeding. 7. Cholestatic jaundice of pregnancy or jaundice with prior pill use. 8. Hepatic adenomas or carcinomas. 9. Known or suspected pregnancy.

WARNINGS

Cigarette smoking increases the risk of serious cardiovascular side effects from oral contraceptive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use oral contraceptives should be strongly advised not to smoke.

The use of oral contraceptives is associated with increased risks of several serious conditions including myocardial infarction, thromboembolism, stroke, hepatic neoplasia, and gallbladder disease, although the risk of serious morbidity or mortality is very small in healthy women without underlying risk factors. The risk of morbidity and mortality increases significantly in the presence of other underlying risk factors such as hypertension, hyperlipidemias, obesity and diabetes. Practitioners prescribing oral contraceptives should be familiar with the following information relating to these risks. The information contained in this brief summary is principally based on studies carried out in patients who used oral contraceptives with higher formulations of estrogens and progestogens than those in common use today. The effect of long term use of the oral contraceptives with lower formulations of both estrogens and progestogens remains to be determined. Throughout this brief summary epidemiological studies reported are of two types: retrospective or case control studies and prospective or cohort studies. Case control studies provide a measure of the relative risk of a disease, namely a *ratio* of the incidence of a disease among oral contraceptive users to that among nonusers. The relative risk does not provide information on the actual clinical occurrence of a disease. Cohort studies provide a measure of attributable risk, which is the *difference* in the incidence of disease between oral contraceptive users and nonusers. The attributable risk does provide information about the actual occurrence of a disease in the population. For further information, the reader is referred to a text on epidemiological methods. 1. THROMBOEMBOLIC DISORDERS AND OTHER VASCULAR PROBLEMS. a. Myocardial Infarction. An increased risk of myocardial infarction has been associated with oral contraceptive use. This risk is primarily in smokers or women with other underlying risk factors for coronary artery disease such as hypertension, hypercholesterolemia, morbid obesity, and diabetes. The relative risk of heart attack for current oral contraceptive users has been estimated to be two to six. The risk is very low under the age of 30. Smoking in combination with oral contraceptive use has been shown to contribute substantially to the incidence of myocardial infarctions in women in their mid-thirties or older with smoking accounting for the majority of excess cases. Mortality rates associated with circulatory disease have been shown to increase substantially in smokers, especially in those 35 years of age and older among women who use oral contraceptives. Oral contraceptives may compound the effects of well-known risk factors, such as hypertension, diabetes, hyperlipidemias, age and obesity. In particular, some progestogens are known to decrease HDL cholesterol and cause glucose intolerance, while estrogens may create a state of hyperinsulinism. Oral contraceptives have been shown to increase blood pressure among users (see section 9 in WARNINGS). Similar effects on risk factors have been associated with an increased risk of heart disease. Oral contraceptives must be used with caution in women with cardiovascular disease risk factors. b. Thromboembolism. An increased risk of thromboembolic and thrombotic disease associated with the use of oral contraceptives is well established. Case control studies have found the relative risk of users compared to non-users to be 3 for the first episode of superficial venous thrombosis, 4 to 11 for deep vein thrombosis or pulmonary embolism, and 1.5 to 6 for women with predisposing conditions for venous thromboembolic disease. Cohort studies have shown the relative risk to be somewhat lower, about 3 for new cases and about 4.5 for new cases requiring hospitalization. The risk of thromboembolic disease associated with oral contraceptives is not related to length of use and disappears after pill use is stopped. A two- to four-fold increase in relative risk of post-operative thromboembolic complications has been reported with the use of oral contraceptives. The relative risk of venous thrombosis in women who have predisposing conditions is twice that of women without such medical conditions. If feasible, oral contraceptives should be discontinued at least four weeks prior to and for two weeks after elective surgery of a type associated with an increase in risk of thromboembolism and during and following prolonged immobilization. Since the immediate postpartum period is also associated with an increased risk of thromboembolism, oral contraceptives should be started no earlier than four weeks after delivery in women who elect not to breast feed. c. Cerebrovascular diseases. Oral contraceptives have been shown to increase both the relative and attributable risks of cerebrovascular events (thrombotic and hemorrhagic strokes), although, in general, the risk is greatest among older (>35 years), hypertensive women who also smoke. Hypertension was found to be a risk factor for both users and non-users, for both types of strokes, and smoking interacted to increase the risk of stroke. In a large study, the relative risk of thrombotic strokes has been shown to range from 3 for normotensive users to 14 for users with severe hypertension. The relative risk of hemorrhagic stroke is reported to be 1.2 for nonsmokers who used oral contraceptives, 2.6 for smokers who did not use oral contraceptives, 76 for smokers who used oral contraceptives, 1.8 for normotensive users and 25.7 for users with severe hypertension. The attributable risk is also greater in older women. d. Dose-related risk of vascular disease from oral contraceptives. A positive association has been observed between the amount of estrogen and progestogen in oral contraceptives and the risk of vascular disease. A decline in serum high density lipoproteins (HDL) has been reported with many progestational agents. A decline in serum high density lipoproteins has been associated with an increased incidence of ischemic heart disease. Because estrogens increase HDL cholesterol, the net effect of an oral contraceptive depends on a balance achieved between doses of estrogen and progestogen and the activity of the progestogen used in the contraceptive. The activity and amount of both hormones should be considered in the choice of an oral contraceptive. Minimizing exposure to estrogen and progestogen is in keeping with good principles of therapeutics. For any particular estrogen/progestogen combination, the dosage regimen prescribed should be one which contains the least amount of estrogen and progestogen that is compatible with a low failure rate and the needs of the individual patient. New acceptors of oral contraceptive agents should be started on preparations containing 0.035 mg or less of estrogen. e. Persistence of risk of vascular disease. There are two studies which have shown persistence of risk of vascular disease for ever-users of oral contraceptives. In a study in the United States, the risk of developing myocardial infarction after discontinuing oral contraceptives persists for at least 9 years for women 40-49 years who had used oral contraceptives for five or more years, but this increased risk was not demonstrated in other age groups. In another study in Great Britain, the risk of developing cerebrovascular disease persisted for at least 6 years after discontinuation of oral contraceptives, although excess risk was very small. However, both studies were performed with oral contraceptive formulations containing 50 micrograms or higher of estrogens. 2. ESTIMATES OF MORTALITY FROM CONTRACEPTIVE USE. One study gathered data from a variety of sources which have estimated the mortality rate associated with different methods of contraception at different ages. These estimates include the combined risk of death associated with contraceptive methods plus the risk attributable to pregnancy in the event of method failure. Each method of contraception has its specific benefits and risks. The study concluded that with the exception of oral contraceptive users 35 and older who smoke and 40 and older who do not smoke, mortality associated with all methods of birth control is low and below that associated with childbirth. However, smokers 35 and older and non-smokers 40 and older who use oral contraceptives have a significant increase in mortality higher than those using other methods of birth control. These facts must be weighed in conjunction with failure rates for other methods and the risk associated with subsequent pregnancy. 3. CARCINOMA OF THE REPRODUCTIVE ORGANS. Numerous epidemiological studies have been performed on the incidence of breast, endometrial, ovarian and cervical cancer in women using oral contraceptives. While there are conflicting reports most studies suggest that use of oral contraceptives is not associated with an overall increase in the risk of developing breast cancer. Some studies have reported an increased relative risk of developing breast cancer, particularly at a younger age. This increased relative risk appears to be related to duration of use. Some studies suggest that oral contraceptive use has been associated with an increase in the risk of cervical intraepithelial neoplasia in some populations of women. However, there continues to be controversy about the extent to which such findings may be due to differences in sexual behavior and other factors. 4. HEPATIC NEOPLASIA. Benign hepatic adenomas are associated with oral contraceptive use, although the incidence of benign tumors is rare in the United States. Indirect calculations have estimated the attributable risk to be in the range of 3.3 cases/100,000 for users, a risk that increases after four or more years of use especially with oral contraceptives of higher dose. Rupture of benign, hepatic adenomas may cause death through intra-abdominal hemorrhage. Studies from Britain have shown an increased risk of developing hepatocellular carcinoma in long-term (>8 years) oral contraceptive users. However, these cancers are rare in the U.S. and the attributable risk (the excess incidence) of liver cancers in oral contraceptive users approaches less than one per million users. 5. OCULAR LESIONS. There have been clinical case reports of retinal thrombosis associated with the use of oral contraceptives. Oral contraceptives should be discontinued if there is unexplained partial or complete loss of vision; onset of proptosis or diplopia, papilledema, or retinal vascular lesions. Appropriate diagnostic and therapeutic measures should be undertaken immediately. 6. ORAL CONTRACEPTIVE USE BEFORE OR DURING EARLY PREGNANCY. Extensive epidemiological studies have revealed no increased risk of birth defects in women who have used oral contraceptives prior to pregnancy. The majority of recent studies also do not indicate a teratogenic effect, particularly in so far as cardiac anomalies and limb reduction defects are concerned, when taken inadvertently during early pregnancy. The administration of oral contraceptives to induce withdrawal bleeding should not be used as a test for pregnancy. Oral contraceptives should not be used during pregnancy to treat threatened or habitual abortion. It is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing oral contraceptive use. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. Oral contraceptive use should be discontinued until pregnancy is ruled out. 7. GALLBLADDER DISEASE. Earlier studies have reported an increased lifetime relative risk of gallbladder surgery in users of oral contraceptives and estrogens. More recent studies, however, have shown that the relative risk of developing gallbladder disease among oral contraceptive users may be minimal. The recent findings of minimal risk may be related to the use of oral contraceptive formulations containing lower hormonal doses of estrogens and progestogens. 8. CARBOHYDRATE AND LIPID METABOLIC EFFECTS. Oral contraceptives have been shown to cause a decrease in glucose tolerance in a significant percentage of users. This effect has been shown to be directly related to estrogen dose. Progestogens increase insulin secretion and create insulin resistance, this effect varying with different progestational agents. However, in the non-diabetic woman, oral contraceptives appear to have no effect on fasting blood glucose. Because of these demonstrated effects prediabetic and diabetic women in particular should be carefully monitored while taking oral contraceptives. A small proportion of women will have persistent hypertriglyceridemia while on the pill. As discussed earlier (see WARNINGS 1a and 1d), changes in serum triglycerides and lipoprotein levels have been reported in oral contraceptive users. 9. ELEVATED BLOOD PRESSURE. An increase in blood pressure has been reported in women taking oral contraceptives, and this increase is more likely in older oral contraceptive users and with extended duration of use. Data from the Royal College of General Practitioners and subsequent randomized trials have shown that the incidence of hypertension increases with increasing progestational activity. Women with a history of hypertension or hypertension-related diseases, or renal disease, should be encouraged to use another method of contraception. If women elect to use oral contraceptives, they should be monitored closely and if significant elevation of blood pressure occurs, oral contraceptives should be discontinued. For most women, elevated blood pressure will return to normal after stopping oral contraceptives, and there is no difference in the occurrence of hypertension between former and never users. 10. HEADACHE. The onset or exacerbation of migraine or development of headache with a new pattern which is recurrent, persistent or severe requires discontinuation of oral contraceptives and evaluation of the cause. 11. BLEEDING IRREGULARITIES. Breakthrough bleeding and spotting are sometimes encountered in patients on oral contraceptives, especially during the first three months of use. Non-hormonal causes should be considered and adequate diagnostic measures taken to rule out malignancy or pregnancy in the event of breakthrough bleeding as in the case of any abnormal vaginal bleeding. If pathology has been excluded, time or a change to another formulation may solve the problem. In the event of amenorrhea, pregnancy should be ruled out. Some women may encounter post-pill amenorrhea or oligomenorrhea, especially when such a condition was preexistent. 12. ECTOPIC PREGNANCY. Ectopic as well as intrauterine pregnancy may occur in contraceptive failures. **PRECAUTIONS:** 1. PHYSICAL EXAMINATION AND FOLLOW UP. A complete medical history and physical examination should be taken prior to the initiation or reinstitution of oral contraceptives and at least annually during use of oral contraceptives. These physical examinations should include special reference to blood pressure, breasts, abdomen and pelvic organs, including cervical cytology, and relevant laboratory tests. In case of undiagnosed persistent or recurrent abnormal vaginal bleeding, appropriate diagnostic measures should be conducted to rule out malignancy. Women with a strong family history of breast cancer or who have breast nodules should be monitored with particular care. 2. LIPID DISORDERS. Women who are being treated for hyperlipidemias should be followed closely if they elect to use oral contraceptives. Some progestogens may elevate LDL levels and may render the control of hyperlipidemias more difficult. 3. LIVER FUNCTION. If jaundice develops in any woman receiving such drugs, the medication should be discontinued. Steroid hormones may be poorly metabolized in patients with impaired liver function. 4. FLUID RETENTION. Oral contraceptives may cause some degree of fluid retention. They should be prescribed with caution, and only with careful monitoring, in patients with conditions which might be aggravated by fluid retention. 5. EMOTIONAL DISORDERS. Women with a history of depression should be carefully observed and the drug discontinued if depression recurs to a serious degree. 6. CONTACT LENSES. Contact lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist. 7. DRUG INTERACTIONS. Reduced efficacy and increased incidence of breakthrough bleeding and menstrual irregularities have been associated with concomitant use of rifampin. A similar association, though less marked, has been suggested with barbiturates, phenylbutazone, phenytoin sodium, and possibly with griseofulvin, ampicillin and tetracyclines. 8. INTERACTIONS WITH LABORATORY TESTS. Certain endocrine and liver function tests and blood components may be affected by oral contraceptives: a. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3, increased norepinephrine-induced platelet aggregability. b. Increased thyroid binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by protein-bound iodine (PBI), T4 by column or by radio-immunoassay. Free T3 resin uptake is decreased, reflecting the elevated TBG, free T4 concentration is unaltered. c. Other binding proteins may be elevated in serum. d. Sex-binding globulins are increased and result in elevated levels of total circulating sex steroids and corticoids; however, free or biologically active levels remain unchanged. e. Triglycerides may be increased. f. Glucose tolerance may be decreased. g. Serum folate levels may be depressed by oral contraceptive therapy. This may be of clinical significance if a woman becomes pregnant shortly after discontinuing oral contraceptives. 9. CARCINOGENESIS. See WARNINGS section. 10. PREGNANCY. Pregnancy Category X. See CONTRAINDICATIONS and WARNINGS sections. 11. NURSING MOTHERS. Small amounts of oral contraceptive steroids have been identified in the milk of nursing mothers and a few adverse effects on the child have been reported, including jaundice and breast enlargement. In addition, oral contraceptives given in the postpartum period may interfere with lactation by decreasing the quantity and quality of breast milk. If possible, the nursing mother should be advised not to use oral contraceptives but to use other forms of contraception until she has completely weaned her child. **INFORMATION FOR THE PATIENT: See Patient Package Insert. ADVERSE REACTIONS:** An increased risk of the following serious adverse reactions has been associated with the use of oral contraceptives (see WARNINGS section). Thrombophlebitis and venous thrombosis with or without embolism. Arterial thromboembolism. Pulmonary embolism. Myocardial infarction. Cerebral hemorrhage. Cerebral thrombosis. Hypertension. Gallbladder disease. Hepatic adenomas or benign liver tumors. The following adverse reactions have been reported in patients receiving oral contraceptives and are believed to be drug-related: Nausea. Vomiting. Gastrointestinal symptoms (such as abdominal cramps and bloating). Breakthrough bleeding. Spotting. Change in menstrual flow. Amenorrhea. Temporary infertility after discontinuation of treatment. Edema. Melasma which may persist. Breast changes: tenderness, enlargement, secretion. Change in weight (increase or decrease). Change in cervical erosion and secretion. Diminution in lactation when given immediately postpartum. Cholestatic jaundice. Migraine. Rash (allergic). Mental depression. Reduced tolerance to carbohydrates. Vaginal candidiasis. Change in corneal curvature (steepening). Intolerance to contact lenses. The following adverse reactions have been reported in users of oral contraceptives and the association has been neither confirmed nor refuted: Pre-menstrual syndrome. Cataracts. Changes in appetite. Cystitis-like syndrome. Headache. Nervousness. Dizziness. Hirsutism. Loss of scalp hair. Erythema multiform, Erythema nodosum. Hemorrhagic eruption. Vaginitis. Porphyria. Impaired renal function. Hemolytic uremic syndrome. Acne. Changes in libido. Colitis. **OVERDOSAGE:** Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea and withdrawal bleeding may occur in females.

IN THE MANAGEMENT OF ENDOMETRIOSIS

enough is enough

Power to suppress estradiol to levels that result in effective relief

- Lowers serum estradiol to near menopausal levels within approximately 1 month, and maintains those levels throughout the 6-month course of therapy.*
- 92% of patients (n = 143) were symptom-free or had only mild symptoms following a 6-month course of therapy.
- Retreatment cannot be recommended since safety data for retreatment are not currently available.

Control in the management of hypoestrogenic and therapeutic effects

- A small impact on bone,† as well as a predictable and manageable hypoestrogenic profile.
- Lets you terminate treatment immediately should that be required for any reason, unlike the depot form of GnRH‡ therapy.

*Pregnancy should be ruled out before therapy with SYNAREL is initiated, and patients should be advised to use a nonhormonal method of contraception when taking SYNAREL.
†There is a small loss in bone density with 6-month treatment, some of which may not be reversible. During one treatment period the bone loss should not be important. ‡Gonadotropin-releasing hormone analog. Please see brief summary of prescribing information on next page.

SYNAREL® (NAFARELIN ACETATE)
NASAL SOLUTION, 2 MG/ML

Setting The Pace In Endometriosis Therapy

BRIEF SUMMARY

SYNAREL® Nasal Solution contains nafarelin acetate (2 mg/mL, expressed as nafarelin base), benzalkonium chloride, glacial acetic acid, sodium hydroxide or hydrochloric acid, sorbitol, and purified water.

INDICATIONS AND USAGE: For management of endometriosis. Experience is limited to women 18 years and older treated for 6 months.

CONTRAINDICATIONS: Hypersensitivity to GnRH, GnRH agonist analogs or any excipients in SYNAREL; undiagnosed abnormal vaginal bleeding; pregnancy or possibility of pregnancy while taking the drug because SYNAREL may cause fetal harm when administered to a pregnant woman. If SYNAREL is used during pregnancy or if the patient becomes pregnant while taking this drug, she should be apprised of the potential hazard to the fetus; use in women who are breast feeding.

WARNINGS: Safe use in pregnancy has not been established clinically. Before starting treatment pregnancy must be excluded.

When used regularly at the recommended dose, SYNAREL usually inhibits ovulation and stops menstruation. Contraception is not insured, particularly if patients miss successive doses. Therefore, patients should use nonhormonal contraception. Advise patients to see their physician if they believe they may be pregnant. If a patient becomes pregnant during treatment, discontinue the drug; apprise patient of the potential risk to the fetus.

PRECAUTIONS General: Ovarian cysts have been reported in the first 2 months of therapy. These may resolve spontaneously or may require drug discontinuation or surgery.

Information for Patients: 1. Since menstruation should stop with SYNAREL, the patient should notify her physician if regular menstruation persists. If patient is compliant and menstruation persists to second month, consider doubling the dose. Counsel noncompliant patients on importance of taking SYNAREL regularly. 2. Patients should not use SYNAREL if pregnant, breast feeding, have undiagnosed abnormal vaginal bleeding, or are allergic to any of its ingredients. 3. Safe use in pregnancy has not been established. Therefore, a nonhormonal method of contraception should be used during treatment. If a patient becomes pregnant during treatment, she should discontinue the drug and consult her physician. 4. Adverse events occurring most frequently in clinical studies are associated with hypoestrogenism. Nasal irritation occurred in about 10% of patients. 5. Induced hypoestrogenic state results in a small loss in bone density over a 6-month treatment course. Some of this loss may not be reversible. During one six-month treatment period, this should not be important. In patients with major risk factors for decreased bone mineral content, i.e., chronic alcohol and/or tobacco use, strong family history of osteoporosis, or chronic use of drugs that can reduce bone mass such as anticonvulsants or corticosteroids, SYNAREL may pose additional risk. In these patients risks and benefits must be weighed carefully. Repeated courses of treatment with GnRH analogs are not advisable in patients with major risk factors for loss of bone mineral content. 6. Patients with intercurrent rhinitis should consult their physician for use of a topical nasal decongestant. If a topical nasal decongestant is required during treatment, it must be used at least 30 minutes after SYNAREL dosing to decrease the possibility of reducing drug absorption. 7. Retreatment cannot be recommended since safety data beyond 6 months are not available.

Drug Interactions: No pharmacokinetic-based drug-drug interaction studies have been conducted. Nafarelin acetate is a peptide primarily degraded by peptidase and not by cytochrome P-450 enzymes, and is only about 80% bound to plasma proteins at 4°C; therefore drug interactions would not be expected to occur.

Drug/Laboratory Test Interactions: SYNAREL in therapeutic doses suppresses the pituitary-gonadal system. Normal function is usually restored 4-8 weeks after treatment is discontinued. Therefore, diagnostic tests of pituitary gonadotropic and gonadal functions during treatment and up to 4-8 weeks after discontinuation of SYNAREL may be misleading.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Carcinogenicity studies were conducted in rats and mice at intramuscular doses up to 110 times and 560 times the maximum recommended human intranasal dose, respectively. These multiples of the human dose are based on the relative bioavailability of the drug by the two routes of administration. As with other GnRH agonists, nafarelin acetate given to laboratory rodents at high doses for prolonged periods induced hyperplasia and/or neoplasia of endocrine organs. At 24 months, there was an increase in the incidence of pituitary tumors (adenoma/carcinoma) in high-dose female rats and a dose-related increase in male rats. There was an increase in pancreatic islet cell adenomas in both sexes, and in benign testicular and ovarian tumors in the treated groups. There was a dose-related increase in benign adrenal medullary tumors in treated female rats. In mice, there was a dose-related increase in Harderian gland tumors in males and an increase in pituitary adenomas in high-dose females. No metastases of these tumors were observed. It is known that tumorigenicity in rodents is particularly sensitive to hormonal stimulation.

Mutagenicity studies using bacterial, yeast, and mammalian systems provided no evidence of mutagenic potential.

Reproduction studies in male and female rats have shown full reversibility of fertility suppression when treatment was discontinued after continuous administration for up to 6 months.

Pregnancy, Teratogenic Effects: *Pregnancy Category X.* Intramuscular SYNAREL was administered to rats throughout gestation at about 0.5, 2, and 7 times the maximum recommended human intranasal dose based on the relative bioavailability by the two routes of administration. An increase in major fetal abnormalities was seen in 4/80 fetuses at the highest dose. A similar study at the same doses in rats and studies in mice and rabbits at doses up to 600 μg/kg/day and 0.18 μg/kg/day, respectively, failed to demonstrate an increase in fetal abnormalities after administration throughout gestation. In rats and rabbits, there was a dose-related increase in fetal mortality and a decrease in fetal weight with the highest dose.

Nursing Mothers: It is not known whether SYNAREL is excreted in human milk. Because many drugs are excreted in human milk, and because the effects of SYNAREL on lactation and/or the breastfed child have not been determined, SYNAREL should not be used by nursing mothers.

Pediatric Use: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS: The most frequently reported adverse reactions were those related to hypoestrogenism. In controlled studies comparing SYNAREL (400 μg/day) and danazol (600 or 800 mg/day), the following adverse reactions were most frequently reported and thought to be drug-related.

Hypoestrogenic: hot flashes (SYNAREL 90%, danazol 69%), decreased libido (22%, 7%), vaginal dryness (19%, 7%), headaches (19%, 21%), emotional lability (15%, 18%), insomnia (8%, 4%); **Androgenic:** acne (13%, 20%), myalgia (10%, 23%), reduced breast size (10%, 16%), edema (8%, 23%), seborrhea (8%, 17%), weight gain (8%, 28%), hirsutism (2%, 6%), increased libido (1%, 6%); **Local:** nasal irritation (10%, 3%); **Miscellaneous:** depression (2%, 5%), weight loss (1%, 3%).

Less than 1% of patients experienced paresthesia, palpitations, chloasma, maculopapular rash, eye pain, urticaria, asthenia, lactation, breast engorgement, and arthralgia. In clinical trials, immediate hypersensitivity thought to be possibly or probably related to nafarelin occurred in 3 (0.2%) of 1509 healthy subjects or patients.

Changes in Bone Density: After 6 months' treatment vertebral trabecular bone density and total vertebral bone mass, measured by quantitative computed tomography (QCT), decreased by an average of 8.7% and 4.3%, respectively, compared to pretreatment levels. There was partial recovery of bone density post-treatment; the average trabecular bone density and total bone mass were 4.9% and 3.3% less than pretreatment levels, respectively. Total vertebral bone mass, measured by dual photon absorptiometry (DPA), decreased by a mean of 5.9% at end of treatment. Mean total vertebral mass, re-examined by DPA 6 months post-treatment, was 1.4% below pretreatment levels. There was little, if any, decrease in the mineral content in compact bone of the distal radius and second metacarpal. Use for longer than the recommended 6 months or in presence of other known risk factors for decreased bone mineral content may cause additional bone loss.

Changes in Laboratory Values: *Plasma enzymes.* During clinical trials SGOT and SGPT levels were more than twice the upper limit of normal in only one patient each. There was no other evidence of abnormal liver function and levels returned to normal after treatment was stopped.

Lipids. At enrollment and at end of treatment, 9% of patients on SYNAREL 400 μg/day and 2% on danazol had total cholesterol values above 250 mg/dL.

Of those with pretreatment cholesterol values below 250 mg/dL, 6% on SYNAREL and 18% on danazol had post-treatment values above 250 mg/dL.

Mean (± SEM) pretreatment values for total cholesterol from all patients were 191.8 (4.3) mg/dL in the SYNAREL group and 193.1 (4.6) mg/dL in the danazol group. At the end of treatment, mean values from all patients were 204.5 (4.8) mg/dL in the SYNAREL group and 207.7 (5.1) mg/dL in the danazol group. These increases from pretreatment values were significant ($p < 0.05$) in both groups.

Triglycerides were increased above the upper limit of 150 mg/dL in 12% of the patients on SYNAREL and in 7% of the patients on danazol.

At the end of treatment, no patients on SYNAREL had abnormally low HDL cholesterol fractions (< 30 mg/dL) compared with 43% of patients on danazol. No patients on SYNAREL had abnormally high LDL cholesterol fractions (> 190 mg/dL) compared with 15% of those on danazol. There was no increase in the LDL/HDL ratio in patients on SYNAREL, but approximately a 2-fold increase in the LDL/HDL ratio in patients on danazol.

Other changes. In comparative studies, the following changes were seen in approximately 10% to 15% of patients. SYNAREL was associated with elevations of plasma phosphorous and eosinophil counts, and decreases in serum calcium and WBC counts. Danazol therapy was associated with an increase of hematocrit and WBC.

OVERDOSAGE: At present there is no clinical evidence of adverse effects following overdosage of GnRH analogs.

New 2nd Edition!

COMPREHENSIVE GYNECOLOGY

Arthur L. Herbst, M.D.; Daniel R. Mishell, Jr., M.D.; Morton A. Stenchever, M.D.; and William Droegemueller, M.D.

The broad scope of this authoritative text covers the most recent advances in the field for residents and practitioners.

- Each chapter begins with a list of key terms and definitions and ends with a list of key points.
- Features increased coverage of perimenopausal and postmenopausal topics and improved coverage of dysfunctional uterine bleeding.

December 1991. Approx. 1,184 pages, 129 ills. (Book Code: 06244)

Also available: **COMPREHENSIVE GYNECOLOGY REVIEW, 2nd Edition** by Holzman, et al. A perfect supplement for Residents preparing for the boards.

December 1991. Approx. 320 pages, 123 ills. (Book Code: 02279)

CEFOTAN® IM/IV

(cefotetan disodium)

Available in 1-gram and 2-gram vials

For Intravenous or Intramuscular Use
PLEASE SEE FULL PRESCRIBING INFORMATION FOR A COMPLETE DESCRIPTION.
A BRIEF SUMMARY FOLLOWS.

INDICATIONS AND USAGE
TREATMENT

CEFOTAN is indicated for the therapeutic treatment of the following infections when caused by susceptible strains of the designated organisms:

Urinary Tract Infections caused by *E. coli, Klebsiella* species (including *K. pneumoniae*), *Proteus mirabilis,* and *Proteus* sp (which may include the organisms now called *Proteus vulgaris, Providencia rettgeri,* and *Morganella morganii*).

Lower Respiratory Tract Infections caused by *Streptococcus pneumoniae* (formerly *D. pneumoniae*), *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Haemophilus influenzae* (including ampicillin-resistant strains), *Klebsiella* species (including *K. pneumoniae*), *E. coli, Proteus mirabilis,* and *Serratia marcescens**.

Skin and Skin Structure Infections due to *Staphylococcus aureus* (penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis, Streptococcus pyogenes, Streptococcus* species (excluding enterococci), *Escherichia coli, Klebsiella pneumoniae, Peptococcus niger**, *Peptostreptococcus* species.

Gynecologic Infections caused by *Staphylococcus aureus* (including penicillinase- and nonpenicillinase-producing strains), *Staphylococcus epidermidis, Streptococcus* species (excluding enterococci), *Streptococcus agalactiae, E. coli, Proteus mirabilis, Neisseria gonorrhoeae,* Bacteroides species (excluding *B. distasonis, B. ovatus, B. thetaiotaomicron*), *Fusobacterium* species*, and gram-positive anaerobic cocci (including *Peptococcus niger* and *Peptostreptococcus* species).

Cefotetan, like other cephalosporins, has no activity against *Chlamydia trachomatis.* Therefore, when cephalosporins are used in the treatment of pelvic inflammatory disease, and *C. trachomatis* is one of the suspected pathogens, appropriate antichlamydial coverage should be added.

Intra-abdominal Infections caused by *E. coli, Klebsiella* species (including *K. pneumoniae*), *Streptococcus* species (excluding enterococci), *Bacteroides* species (excluding *B. distasonis, B. ovatus, B. thetaiotaomicron*) and *Clostridium* species*.

Bone and Joint Infections caused by *Staphylococcus aureus**.

*Efficacy for this organism in this organ system was studied in fewer than ten infections.

Specimens for bacteriological examination should be obtained in order to isolate and identify causative organisms and to determine their susceptibilities to cefotetan. Therapy may be instituted before results of susceptibility studies are known; however, once these results become available, the antibiotic treatment should be adjusted accordingly.

In cases of confirmed or suspected gram-positive or gram-negative sepsis or in patients with other serious infections in which the causative organism has not been identified, it is possible to use CEFOTAN concomitantly with an aminoglycoside. Cefotetan combinations with aminoglycosides have been shown to be synergistic *in vitro* against many Enterobacteriaceae and also some other gram-negative bacteria. The dosage recommended in the labeling of both antibiotics may be given and depends on the severity of the infection and the patient's condition.

NOTE: If CEFOTAN and an aminoglycoside are used concomitantly, renal function should be carefully monitored, especially if higher dosages of the aminoglycoside are to be administered or if therapy is prolonged, because of the potential nephrotoxicity and ototoxicity of aminoglycosidic antibiotics. Although, to date, nephrotoxicity has not been noted when CEFOTAN was given alone, it is possible that nephrotoxicity may be potentiated if CEFOTAN is used concomitantly with an aminoglycoside.

PROPHYLAXIS

The preoperative administration of CEFOTAN may reduce the incidence of certain postoperative infections in patients undergoing surgical procedures that are classified as clean contaminated or potentially contaminated (e.g., cesarean section, abdominal or vaginal hysterectomy, transurethral surgery, biliary tract surgery, and gastrointestinal surgery).

The prophylactic dose of CEFOTAN should be administered 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, CEFOTAN should be administered intravenously after the clamping of the umbilical cord.

If there are signs and symptoms of infection, specimens for culture should be obtained for identification of the causative organism so that appropriate therapeutic measures may be initiated.

CONTRAINDICATIONS

CEFOTAN is contraindicated in patients with known allergy to the cephalosporin group of antibiotics.

WARNINGS

BEFORE THERAPY WITH CEFOTAN IS INSTITUTED, CAREFUL INQUIRY SHOULD BE MADE TO DETERMINE WHETHER THE PATIENT HAS HAD PREVIOUS HYPERSENSITIVITY REACTIONS TO CEFOTETAN DISODIUM, CEPHALOSPORINS, PENICILLINS, OR OTHER DRUGS. IF THIS PRODUCT IS TO BE GIVEN TO PENICILLIN-SENSITIVE PATIENTS, CAUTION SHOULD BE EXERCISED BECAUSE CROSS-HYPERSENSITIVITY AMONG BETA-LACTAM ANTIBIOTICS HAS BEEN CLEARLY DOCUMENTED AND MAY OCCUR IN UP TO 10% OF PATIENTS WITH A HISTORY OF PENICILLIN ALLERGY. IF AN ALLERGIC REACTION TO CEFOTAN OCCURS, DISCONTINUE THE DRUG. SERIOUS ACUTE HYPERSENSITIVITY REACTIONS MAY REQUIRE TREATMENT WITH EPINEPHRINE AND OTHER EMERGENCY MEASURES, INCLUDING OXYGEN, INTRAVENOUS FLUIDS, INTRAVENOUS ANTIHISTAMINES, CORTICOSTEROIDS, PRESSOR AMINES AND AIRWAY MANAGEMENT, AS CLINICALLY INDICATED.

Pseudomembranous colitis has been reported with nearly all antibacterial agents, including cefotetan, and may range from mild to life-threatening. Onset of pseudomembranous colitis symptoms may occur during or after antibiotic treatment or surgical prophylaxis. Therefore, it is important to consider this diagnosis in patients who present with diarrhea subsequent to the administration of antibacterial agents.

Treatment with antibacterial agents alters the normal flora of the colon and may permit overgrowth of clostridia. Studies indicate that a toxin produced by *Clostridium difficile* is a primary cause of "antibiotic-associated colitis."

After the diagnosis of pseudomembranous colitis has been established, therapeutic measures should be initiated. Mild cases of pseudomembranous colitis usually respond to discontinuation of the drug alone. In moderate to severe cases, consideration should be given to management with fluids and electrolytes, protein supplementation, and treatment with an oral antibacterial drug effective against *Clostridium difficile.*

In common with many other broad-spectrum antibiotics, CEFOTAN may be associated with a fall in prothrombin activity and, possibly, subsequent bleeding. Those at increased risk include patients with renal or hepatobiliary impairment or poor nutritional state, the elderly, and patients with cancer. Prothrombin time should be monitored and exogenous vitamin K administered as indicated.

PRECAUTIONS

General: As with other broad-spectrum antibiotics, prolonged use of CEFOTAN may result in overgrowth of nonsusceptible organisms. Careful observation of the patient is essential. If superinfection does occur during therapy, appropriate measures should be taken.

CEFOTAN should be used with caution in individuals with a history of gastrointestinal disease, particularly colitis.

Information for Patients: As with some other cephalosporins, a disulfiram-like reaction characterized by flushing, sweating, headache, and tachycardia may occur when alcohol (beer, wine, etc.) is ingested within 72 hours after CEFOTAN administration. Patients should be cautioned about the ingestion of alcoholic beverages following the administration of CEFOTAN.

Drug Interactions: Although to date nephrotoxicity has not been noted when CEFOTAN was given alone, it is possible that nephrotoxicity may be potentiated if CEFOTAN is used concomitantly with an aminoglycoside.

Drug/Laboratory Test Interactions: The administration of CEFOTAN may result in a false-positive reaction for glucose in the urine using Clinitest®†, Benedict's solution, or Fehling's solution. It is recommended that glucose tests based on enzymatic glucose oxidase be used.

As with other cephalosporins, high concentrations of cefotetan may interfere with measurement of serum and urine creatinine levels by Jaffe reaction and produce false increases in the levels of creatinine reported.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Although long-term studies in animals have not been performed to evaluate carcinogenic potential, no mutagenic potential of cefotetan was found in standard laboratory tests.

Cefotetan has adverse effects on the testes of prepubertal rats. Subcutaneous administration of 500 mg/kg/day (approximately 8-16 times the usual adult human dose) on days 6-35 of life (thought to be developmentally analogous to late childhood and prepuberty in humans) resulted in reduced testicular weight and seminiferous tubule degeneration in 10 of 10 animals. Affected cells included spermatogonia and spermatocytes; Sertoli and Leydig cells were unaffected. Incidence and severity of lesions were dose-dependent; at 120 mg/kg/day (approximately 2-4 times the usual human dose) only 1 of 10 treated animals was affected, and the degree of degeneration was mild.

Similar lesions have been observed in experiments of comparable design with other methylthiotetrazole-containing antibiotics and impaired fertility has been reported, particularly at high dose levels. No testicular effects were observed in 7-week-old rats treated with up to 1000 mg/kg/day SC for 5 weeks, or in infant dogs (3 weeks old) that received up to 300 mg/kg/day IV for 5 weeks. The relevance of these findings to humans is unknown.

Pregnancy: Teratogenic Effects. Pregnancy Category B: Reproduction studies have been performed in rats and monkeys at doses up to 20 times the human dose and have revealed no evidence of impaired fertility or harm to the fetus due to cefotetan. There are, however, no adequate and well-controlled studies in pregnant women. Because animal reproductive studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

Nursing Mothers: Cefotetan is excreted in human milk in very low concentrations. Caution should be exercised when cefotetan is administered to a nursing woman.

Pediatric Use: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS

In clinical studies, the following adverse effects were considered related to CEFOTAN therapy. Those appearing in italics have been reported during postmarketing experience.

Gastrointestinal symptoms occurred in 1.5% of patients; the most frequent were diarrhea (1 in 80) and nausea (1 in 700); *pseudomembranous colitis.* Onset of pseudomembranous colitis symptoms may occur during or after antibiotic treatment or surgical prophylaxis. (See WARNINGS.)

Hematologic laboratory abnormalities occurred in 1.4% of patients and included eosinophilia (1 in 200), positive direct Coombs' test (1 in 250), and thrombocytosis (1 in 300); *agranulocytosis, hemolytic anemia, leukopenia, thrombocytopenia,* and *prolonged prothrombin time.*

Hepatic enzyme elevations occurred in 1.2% of patients and included a rise in SGPT (1 in 150), SGOT (1 in 300), alkaline phosphatase (1 in 700), and LDH (1 in 700).

Hypersensitivity reactions were reported in 1.2% of patients and included rash (1 in 150) and itching (1 in 700); *anaphylactic reactions.*

Local effects were reported in less than 1.0% of patients and included phlebitis at the site of injection (1 in 300), and discomfort (1 in 500).

Miscellaneous: *Fever*

In addition to the adverse reactions listed above which have been observed in patients treated with cefotetan, the following adverse reactions and altered laboratory tests have been reported for cephalosporin-class antibiotics: urticaria, pruritis, Stevens-Johnson syndrome, erythema multiforme, toxic epidermal necrolysis, vomiting, abdominal pain, colitis, superinfection, vaginitis including vaginal candidiasis, renal dysfunction, toxic nephropathy, hepatic dysfunction including cholestasis, aplastic anemia, hemorrhage, increased BUN, increased creatinine, elevated bilirubin, pancytopenia, and neutropenia.

Several cephalosporins have been implicated in triggering seizures, particularly in patients with renal impairment when the dosage was not reduced (see DOSAGE AND ADMINISTRATION and OVERDOSAGE). If seizures associated with drug therapy occur, the drug should be discontinued. Anticonvulsant therapy can be given if clinically indicated.

DOSAGE AND ADMINISTRATION
TREATMENT

The usual adult dosage is 1 or 2 grams of CEFOTAN administered intravenously or intramuscularly every 12 hours for 5 to 10 days. Proper dosage and route of administration should be determined by the condition of the patient, severity of the infection, and susceptibility of the causative organism.

GENERAL GUIDELINES FOR DOSAGE OF CEFOTAN

Type of Infection	Daily Dose	Frequency and Route
Urinary Tract	1-4 grams	500 mg every 12 hours IV or IM 1 or 2 g every 24 hours IV or IM 1 or 2 g every 12 hours IV or IM
Skin & Skin Structure		
Mild-Moderate[a]	2 grams	2 g every 24 hours IV 1 g every 12 hours IV or IM
Severe	4 grams	2 g every 12 hours IV
Other Sites	2-4 grams	1 or 2 g every 12 hours IV or IM
Severe	4 grams	2 g every 12 hours IV
Life-Threatening	6 grams[b]	3 g every 12 hours IV

[a] *K. pneumoniae* skin and skin structure infections should be treated with 1 or 2 grams every 12 hours IV or IM.

[b] Maximum daily dosage should not exceed 6 grams.

If *C. trachomatis* is a suspected pathogen in gynecologic infections, appropriate antichlamydial coverage should be added, since cefotetan has no activity against this organism.

PROPHYLAXIS

To prevent postoperative infection in clean contaminated or potentially contaminated surgery in adults, the recommended dosage is 1 or 2 g of CEFOTAN administered once, intravenously, 30 to 60 minutes prior to surgery. In patients undergoing cesarean section, the dose should be administered as soon as the umbilical cord is clamped.

IMPAIRED RENAL FUNCTION

When renal function is impaired, a reduced dosage schedule must be employed. See FULL PRESCRIBING INFORMATION for a complete description.

NOTE: Parenteral drug products should be inspected visually for particulate matter and discoloration prior to administration whenever solution and container permit.

Transabdominal chorionic villus sampling: A modified freehand ultrasonographically guided technique 512
Lyndon M. Hill, MD, and Steven A. Laifer, MD
Pittsburgh, Pennsylvania

A short piece of extension tubing between the aspirating syringe and chorionic villus sampling needle allows the operator to concentrate on needle placement. An assistant provides appropriate suction for chorionic villus sampling.

The Diabetes in Early Pregnancy Study: Changes in cholesterol, triglycerides, body weight, and blood pressure 513
Charles M. Peterson, MD, Lois Jovanovic-Peterson, MD, James L. Mills, MD, MS, Mary R. Conley, MA, Robert H. Knopp, MD, George F. Reed, PhD, J.H. Aarons, MD, Lewis B. Holmes, MD, Zane Brown, MD, Margot Van Allen, MD, Ralph Schmeltz, MD, Boyd E. Metzger, MD, and The National Institute of Child Health and Human Development–The Diabetes in Early Pregnancy Study
Santa Barbara, California, Bethesda, Maryland, Seattle, Washington, Pittsburgh, Pennsylvania, Boston, Massachusetts, Toronto, Ontario, Canada, and Chicago, Illinois

Pregnant diabetic women were found to have decreased cholesterol and triglyceride levels and increased weight gain and blood pressure values compared with those of controls.

Pelvic inflammatory disease: Findings during inpatient treatment of clinically severe, laparoscopy-documented disease 519
Charles H. Livengood III, MD, Gale B. Hill, PhD, and W. Allen Addison, MD
Durham, North Carolina

Laparoscopy revealed clinical diagnosis and definition of severe pelvic inflammatory disease to be inaccurate and predicted necessary duration of therapy; a comprehensive management plan for patients hospitalized for pelvic inflammatory disease is presented.

Fetal maternal laryngeal papillomatosis in pregnancy: A case report 524
George Helmrich, MD, Thomas M. Stubbs, MD, and Jay Stoerker, PhD
Charlotte, North Carolina

A survivor of childhood disease had a sudden respiratory arrest after minimal symptoms.

The function of elevated plasma fibronectin in preeclampsia 526
Daniel B. Brubaker, DO, Michael G. Ross, MD, and David Marinoff, MD
Torrance and Los Angeles, California

Fibronectin function may be impaired during pregnancy and preeclampsia, and the clinical pathophysiology of preeclampsia may be related to dysfunctional fibronectin.

The Zavanelli maneuver applied to locked twins 532
J.M. Swartjes, MD, O.P. Bleker, MD, PhD, and M.F. Schutte, MD, PhD
Amsterdam, The Netherlands

The Zavanelli maneuver was successfully applied to locked twins (case report); the method may be of value in future cases of interlocking.

Radical hysterectomy for treatment of cervical cancer: A prospective study of two methods of closed-suction drainage 533
Desmond P.J. Barton, MD, Denis Cavanagh, MD, William S. Roberts, MD, Mitchel S. Hoffman, MD, James V. Fiorica, MD, and Michael A. Finan, MD
Tampa, Florida

A single vaginal closed suction drain was safe, efficient, more cost-effective, and more acceptable to patients than three pelvic drains after radical abdominal hysterectomy.

Arterial pressure response to maximal isometric exercise in pregnant women 538
Fred K. Lotgering, MD, PhD, Akkeliene van den Berg, BSc, Piet C. Struijk, BSc, and Henk C.S. Wallenburg, MD, PhD
Rotterdam, The Netherlands

Pregnancy has no significant effect on the pressure response to maximal isometric exercise, during which mean arterial pressure increases by about 50%.

Transvaginal ultrasonographic quantitative assessment of accumulated cul-de-sac fluid 542
Doron J.D. Rosen, MD, Isaac Ben-Nun, MD, Yael Arbel, MD, Marco M. Altaras, MD, Shmuel B. Goldberger, MD, and Yoram Beyth, MD,
Kfar Saba, Israel

Transvaginal ultrasonography was used to quantitatively assess pelvic fluid.

Comparison of thermal injury zones in loop electrical and laser cervical excisional conization 545
Michael S. Baggish, MD, Faith Barash, MD, Yvonne Noel, MD, and Marlon Brooks, MD
Syracuse, New York

Excisional cone specimens obtained by carbon dioxide laser or thin electrical loops demonstrated similar thermal artifacts.

Nematode infections: Is it wise to withhold medical treatment during pregnancy? I. Biliary complications 549
Marco A. Villar L., MD, and Baha M. Sibai, MD
Tegucigalpa, Honduras, and Memphis, Tennessee

Obstetricians must be aware of the unusual presentations of nematode infections to avoid serious complications during pregnancy.

Composite assessment of gestational age: A comparison of institutionally derived and published regression equations 551
Lyndon M. Hill, MD, David Guzick, MD, Joyce Hixson, RDMS, Carol S. Peterson, RDMS, and Dawn M. Rivello, RDMS
Pittsburgh, Pennsylvania

The combination of more than one second-trimester fetal measurement substantially reduces the error of gestational age assessment.

Phase II trial of ifosfamide and mesna in leiomyosarcoma of the uterus: A Gynecologic Oncology Group study 556

Gregory P. Sutton, MD, John A. Blessing, PhD, Rolland J. Barrett, MD, and Ramon McGehee, MD

Indianapolis, Indiana, Buffalo, New York, Winston-Salem, North Carolina, and Jackson, Mississippi

Ifosfamide is an active drug in refractory uterine leiomyosarcoma.

Prenatal diagnosis of autosomal recessive polycystic kidney disease: Variable outcome within one family 560

Richard A. Barth, MD, Ann P. Guillot, MD, Eleanor L. Capeless, MD, and Jackson J.W. Clemmons, MD

Burlington, Vermont

Prenatally diagnosed autosomal recessive polycystic kidney disease in one family had variable outcome, with two newborns dying and one surviving long term.

Laboratory and clinical comparison of a rapid versus a classic progesterone radioimmunoassay for use in determining abnormal and ectopic pregnancies 562

C. Matthew Peterson, MD, Donald Kreger, MD, Pablo Delgado, MD, and Terry T. Hung, MD, PhD

Salt Lake City, Utah, and Miami, Florida

Serum progesterone measurements evaluated retrospectively differentiated abnormal from normal pregnancies but would not have lowered the rate of ruptured ectopic pregnancies compared with prospective studies.

The accuracy of auscultatory detection of fetal cardiac decelerations: A computer simulation 566

Barry S. Schifrin, MD, Jaim Amsel, MA, and Gary Burdorf, PhD

Tarzana, California

This computer-simulated study of the detection of fetal cardiac decelerations underscores potential inaccuracies of this technique.

Successive pregnancies complicated by idiopathic sideroblastic anemia 576

John R. Barton, MD, David C. Shaver, MD, and Baha M. Sibai, MD

Memphis, Tennessee

Periodic transfusions with washed erythrocytes and oral pyridoxine were used in the management of successive pregnancies complicated by idiopathic sideroblastic anemia.

Dysmenorrhea and use of oral contraceptives in adolescent women attending a family planning clinic 578

J. Courtland Robinson, MD, Stacey Plichta, BA, Carol S. Weisman, PhD, Constance A. Nathanson, PhD, and Margaret Ensminger, PhD

Baltimore, Maryland

Female adolescents who experience the reduction of dysmenorrhea with oral contraceptives are significantly more likely to be consistent oral contraceptive users.

Nonsurgical management of penetrating uterine trauma in pregnancy: A case report 583
Debra K. Grubb, MD
Los Angeles, California

Nonsurgical management of stab wounds to a pregnant uterus resulted in a good outcome.

Doppler ultrasonographic features of the developing placental circulation: Correlation with anatomic findings 585
Eric Jauniaux, MD, Davor Jurkovic, MD, Stuart Campbell, MD, and Jean Hustin, MD, PhD
London, England, and Loverval, Belgium

Uterine and umbilical artery Doppler flow velocity waveform characteristics were correlated with the development of the placental circulations between 10 and 17 weeks' gestation.

Routine urine drug screening at the first prenatal visit 588
Garrett H.C. Colmorgen, MD, Cherie Johnson, MD, Martha A. Zazzarino, RNC, and Karen Durinzi, MD
Wilmington and Newark, Delaware

Urine drug screening should be considered as a component of routine prenatal care in populations at high risk for exposure to illicit drugs.

Bilateral choroid plexus cysts in trisomy 21 591
Siegfried Rotmensch, MD, Jia-Sen Luo, MD, Jose A. Nores, MD, Miriam Schoenfeld Dimaio, MD, and John C. Hobbins, MD
New Haven, Connecticut, and Taipei, Taiwan, Republic of China

Bilateral choroid plexus cysts in an otherwise structurally normal fetus with trisomy 21 are described.

Radical hysterectomy in the elderly patient: Analysis of morbidity 593
Carlos Fuchtner, MD, Alberto Manetta, MD, Joan L. Walker, MD, Dennis Emma, PhD, Michael Berman, MD, and Philip J. DiSaia, MD
Long Beach and Orange, California

An analysis of morbidity and mortality after radical hysterectomy between younger and elderly patients with stage IB or IIA carcinoma of the cervix was conducted.

Postpartum paravaginal hematoma and lower-extremity infection 598
Ashwin Chatwani, MD, Todd Shapiro, MD, Amitabh Mitra, MD, Anna LevToaff, MD, and E. Albert Reece, MD
Philadelphia, Pennsylvania

A case of lower extremity infection resulting from obturator internus hematoma after a normal delivery is presented.

Interrelationship and clinical significance of increased resistance in the uterine arteries in patients with hypertension or preeclampsia or both 601
Alexander D. Kofinas, MD, Mary Penry, RN, RDMS, Nicolas V. Simon, MD, and Melissa Swain, RN
York, Pennsylvania, and Winston-Salem, North Carolina

In patients with hypertension or preeclampsia the placental uterine artery is a better predictor of poor outcome than the nonplacental uterine artery and the mean of the two arteries; placental laterality is an additional risk factor for poor outcome.

A PILL WITH A PROGRAM

Only TRI-NORINYL starts your OC patients with The TRI-NORINYL Total Health Program.™

When you start your OC patient with The TRI-NORINYL Total Health Program sample package, you provide the benefits of oral contraception *plus* an exciting new patient-support program.

The TRI-NORINYL Total Health Program sample package contains one cycle of TRI-NORINYL; the attractive Wallette® Pill Dispenser; and a patient Q&A booklet—*plus* the video and instruction guide, *The ACOG Balanced Fitness Workout;* and program membership. The TRI-NORINYL Total Health Program provides a variety of fitness and health information to help women achieve healthier lifestyles.

As part of that goal, Syntex Laboratories is proud to be a sponsor of the American Medical Association's Women's Health Campaign.

For details about The TRI-NORINYL Total Health Program, please contact your Syntex Representative.

Serious as well as minor side effects have been reported following the use of oral contraceptives. These include thrombo-embolic disease.

Please see adjacent page for brief summary of prescribing information.

TRI-NORINYL
TABLETS

(NORETHINDRONE AND ETHINYL ESTRADIOL)

ORAL CONTRACEPTIVE AGENTS: BRIEF SUMMARY

DESCRIPTION

TRI-NORINYL 21-DAY Tablets provide an oral contraceptive regimen of 7 blue tablets followed by 9 yellow-green tablets and 5 more blue tablets. Each blue tablet contains norethindrone 0.5 mg and ethinyl estradiol 0.035 mg and each yellow-green tablet contains norethindrone 1 mg and ethinyl estradiol 0.035 mg.

TRI-NORINYL 28-DAY Tablets provide a continuous oral contraceptive regimen of 7 blue tablets, 9 yellow-green tablets, 5 more blue tablets, and then 7 orange tablets. Each blue tablet contains norethindrone 0.5 mg and ethinyl estradiol 0.035 mg, each yellow-green tablet contains norethindrone 1 mg and ethinyl estradiol 0.035 mg, and each orange tablet contains inert ingredients.

INDICATIONS AND USAGE

Oral contraceptives are indicated for the prevention of pregnancy in women who elect to use these products as a method of contraception.

CONTRAINDICATIONS

Oral contraceptives should not be used in women who have the following conditions: Thrombophlebitis or thromboembolic disorders • A past history of deep vein thrombophlebitis or thromboembolic disorders • Cerebral vascular or coronary artery disease • Known or suspected carcinoma of the breast • Carcinoma of the endometrium, and known or suspected estrogen-dependent neoplasia • Undiagnosed abnormal genital bleeding • Cholestatic jaundice of pregnancy or jaundice with prior pill use • Hepatic adenomas, carcinomas or benign liver tumors • Known or suspected pregnancy

WARNINGS

Cigarette smoking increases the risk of serious cardiovascular side effects from oral contraceptive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use oral contraceptives should be strongly advised not to smoke.

The use of oral contraceptives is associated with increased risks of several serious conditions including myocardial infarction, thromboembolism, stroke, hepatic neoplasia and gallbladder disease, although the risk of serious morbidity and mortality increases significantly in the presence of other underlying risk factors such as hypertension, hyperlipidemias, hypercholesterolemia, obesity and diabetes.

Practitioners prescribing oral contraceptives should be familiar with the following information relating to these risks.

The information contained in this package insert is principally based on studies carried out in patients who used oral contraceptives with formulations containing 0.05 mg or higher of estrogen. The effects of long-term use with lower dose formulations of both estrogens and progestogens remain to be determined.

Throughout this labeling, epidemiological studies reported are of two types: retrospective or case control studies and prospective or cohort studies. Case control studies provide a measure of the relative risk of a disease. Relative risk, the *ratio* of the incidence of a disease among oral contraceptive users to that among non-users, cannot be assessed directly from case control studies, but the odds ratio obtained is a measure of relative risk. The relative risk does not provide information on the actual clinical occurrence of a disease. Cohort studies provide not only a measure of the relative risk but a measure of attributable risk, which is the *difference* in the incidence of disease between oral contraceptive users and non-users. The attributable risk does provide information about the actual occurrence of a disease in the population.

1. THROMBOEMBOLIC DISORDERS AND OTHER VASCULAR PROBLEMS

a. Myocardial infarction

An increased risk of myocardial infarction has been attributed to oral contraceptive use. This risk is primarily in smokers or women with other underlying risk factors for coronary artery disease such as hypertension, hypercholesterolemia, morbid obesity and diabetes. The relative risk of heart attack for current oral contraceptive users has been estimated to be 2 to 6. The risk is very low under the age of 30. However, there is the possibility of a risk of cardiovascular disease even in very young women who take oral contraceptives.

Smoking in combination with oral contraceptive use has been shown to contribute substantially to the incidence of myocardial infarctions in women 35 or older, with smoking accounting for the majority of excess cases.

Mortality rates associated with circulatory disease have been shown to increase substantially in smokers over the age of 35 and non-smokers over the age of 40 among women who use oral contraceptives.

Oral contraceptives may compound the effects of well-known risk factors for coronary artery disease, such as hypertension, diabetes, hyperlipidemias, hypercholesterolemia, age and obesity. In particular, some progestogens are known to decrease HDL cholesterol and impair oral glucose tolerance, while estrogens may create a state of hyperinsulinism. Oral contraceptives have been shown to increase blood pressure among users (see **WARNINGS**, section 9). Similar effects on risk factors have been associated with an increased risk of heart disease. Oral contraceptives must be used with caution in women with cardiovascular disease risk factors.

b. Thromboembolism

An increased risk of thromboembolic and thrombotic disease associated with the use of oral contraceptives is well established. Case control studies have found the relative risk of users compared to non-users to be 3 for the first episode of superficial venous thrombosis, 4 to 11 for deep vein thrombosis or pulmonary embolism, and 1.5 to 6 for women with predisposing conditions for venous thromboembolic disease. One cohort study has shown the relative risk to be somewhat lower, about 3 for new cases (subjects with no past history of venous thrombosis or varicose veins) and about 4.5 for new cases requiring hospitalization. The risk of thromboembolic disease due to oral contraceptives is not related to length of use and disappears after pill use is stopped.

A 2- to 6-fold increase in relative risk of post-operative thromboembolic complications has been reported with the use of oral contraceptives. If feasible, oral contraceptives should be discontinued at least 4 weeks prior to and for 2 weeks after elective surgery and during and following prolonged immobilization. Since the immediate postpartum period also is associated with an increased risk of thromboembolism, oral contraceptives should be started no earlier than 4 to 6 weeks after delivery in women who elect not to breast feed.

c. Cerebrovascular diseases

An increase in both the relative and attributable risks of cerebrovascular events (thrombotic and hemorrhagic strokes) has been shown in users of oral contraceptives. In general, the risk is greatest among older (>35 years), hypertensive women who also smoke. Hypertension was found to be a risk factor for both users and non-users for both types of strokes while smoking interacted to increase the risk for hemorrhagic strokes.

In a large study, the relative risk of thrombotic strokes has been shown to range from 3 for normotensive users to 14 for users with severe hypertension. The relative risk of hemorrhagic stroke is reported to be 1.2 for non-smokers who used oral contraceptives, 2.6 for smokers who did not use oral contraceptives, 7.6 for smokers who used oral contraceptives, 1.8 for normotensive users and 25.7 for users with severe hypertension. The attributable risk also is greater in women 35 or older and among smokers.

d. Dose-related risk of vascular disease from oral contraceptives

A positive association has been observed between the amount of estrogen and progestogen in oral contraceptives and the risk of vascular disease. A decline in serum high density lipoproteins (HDL) has been reported with some progestational agents. A decline in serum high density lipoproteins has been associated with an increased incidence of ischemic heart disease. Because estrogens increase HDL cholesterol, the net effect of an oral contraceptive depends on a balance achieved between doses of estrogen and progestogen and the nature and absolute amount of progestogens used in the contraceptives. The amount of both hormones should be considered in the choice of an oral contraceptive.

Minimizing exposure to estrogen and progestogen is in keeping with good principles of therapeutics. For any particular estrogen/progestogen combination, the dosage regimen prescribed should be one which contains the least amount of estrogen and progestogen that is compatible with a low failure rate and the needs of the individual patient. New acceptors of oral contraceptive agents should be started on preparations containing the lowest estrogen content that produces satisfactory results for the individual.

e. Persistence of risk of vascular disease

There are three studies which have shown persistence of risk of vascular disease for ever-users of oral contraceptives. In a study in the United States, the risk of developing myocardial infarction after discontinuing oral contraceptives persists for at least 9 years for women 40–49 years who had used oral contraceptives for 5 or more years, but this increased risk was not demonstrated in other age groups. In another study in Great Britain, the risk of developing cerebrovascular disease persisted for at least 6 years after discontinuation of oral contraceptives, although excess risk was very small. Subarachnoid hemorrhage also has a significantly increased relative risk after termination of use of oral contraceptives. However, these studies were performed with oral contraceptive formulations containing 0.05 mg or higher of estrogen.

2. ESTIMATES OF MORTALITY FROM CONTRACEPTIVE USE

One study gathered data from a variety of sources which have estimated the mortality rates associated with different methods of contraception at different ages. These estimates include the combined risk of death associated with contraceptive methods plus the risk attributable to pregnancy in the event of method failure. Each method of contraception has its specific benefits and risks. The study concluded that with the exception of oral contraceptive users 35 and older who smoke and 40 and older who do not smoke, mortality associated with all methods of birth control is low and below that associated with childbirth. The observation of a possible increase in risk of mortality with age for oral contraceptive users is based on data gathered in the 1970s—but not reported in the U.S. until 1983. However, current clinical practice involves the use of lower estrogen dose formulations combined with careful restriction of oral contraceptive use to women who do not have the various risk factors listed in this labeling.

Because of these changes in practice and, also, because of some limited new data which suggest that the risk of cardiovascular disease with the use of oral contraceptives may now be less than previously observed, the Fertility and Maternal Health Drugs Advisory Committee was asked to review the topic in 1989. The Committee concluded that although cardiovascular disease risks may be increased with oral contraceptive use after age 40 in healthy non-smoking women (even with the newer low-dose formulations), there are greater potential health risks associated with pregnancy in older women and with the alternative surgical and medical procedures which may be necessary if such women do not have access to effective and acceptable means of contraception.

Therefore, the Committee recommended that the benefits of oral contraceptive use by healthy non-smoking women over 40 may outweigh the possible risks. Of course, older women, as all women who take oral contraceptives, should take the lowest possible dose formulation that is effective.

3. CARCINOMA OF THE BREAST AND REPRODUCTIVE ORGANS

Numerous epidemiological studies have been performed on the incidence of breast, endometrial, ovarian and cervical cancer in women using oral contraceptives. The evidence in the literature suggests that use of oral contraceptives is not associated with an increase in the risk of developing breast cancer, regardless of the age and parity of first use or with most of the marketed brands and doses. The Cancer and Steroid Hormone study also showed no latent effect on the risk of breast cancer for at least a decade following long-term use. A few studies have shown a slightly increased relative risk of developing breast cancer, although the methodology of these studies, which included differences in examination of users and non-users and differences in age at start of use, has been questioned. Some studies have reported an increased relative risk of developing breast cancer, particularly at a younger age. This increased relative risk appears to be related to duration of use.

Some studies suggest that oral contraceptive use has been associated with an increase in the risk of cervical intraepithelial neoplasia in some populations of women. However, there continues to be controversy about the extent to which such findings may be due to differences in sexual behavior and other factors.

In spite of many studies of the relationship between oral contraceptive use and breast or cervical cancers, a cause and effect relationship has not been established.

4. HEPATIC NEOPLASIA

Benign hepatic adenomas are associated with oral contraceptive use although the incidence of benign tumors is rare in the United States. Indirect calculations have estimated the attributable risk to be in the range of 3.3 cases per 100,000 for users, a risk that increases after 4 or more years of use. Rupture of rare, benign, hepatic adenomas may cause death through intra-abdominal hemorrhage.

Studies in the United States and Britain have shown an increased risk of developing hepatocellular carcinoma in long-term (>8 years) oral contraceptive users. However, these cancers are extremely rare in the United States and the attributable risk (the excess incidence) of liver cancers in oral contraceptive users is less than 1 per 1,000,000 users.

5. OCULAR LESIONS

There have been clinical case reports of retinal thrombosis associated with the use of oral contraceptives. Oral contraceptives should be discontinued if there is unexplained partial or complete loss of vision; onset of proptosis or diplopia; papilledema; or retinal vascular lesions. Appropriate diagnostic and therapeutic measures should be undertaken immediately.

6. ORAL CONTRACEPTIVE USE BEFORE OR DURING EARLY PREGNANCY

Extensive epidemiological studies have revealed no increased risk of birth defects in women who have used oral contraceptives prior to pregnancy. More recent studies do not suggest a teratogenic effect, particularly insofar as cardiac anomalies and limb reduction defects are concerned, when taken inadvertently during early pregnancy.

The administration of oral contraceptives to induce withdrawal bleeding should not be used as a test for pregnancy. Oral contraceptives should not be used during pregnancy to treat threatened or habitual abortion.

It is recommended that for any patient who has missed 2 consecutive periods, pregnancy should be ruled out before continuing oral contraceptive use. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. Oral contraceptive use should be discontinued if pregnancy is confirmed.

7. GALLBLADDER DISEASE

Earlier studies have reported an increased lifetime relative risk of gallbladder surgery in users of oral contraceptives and estrogens. More recent studies, however, have shown that the relative risk of developing gallbladder disease among oral contraceptive users may be minimal. The recent findings of minimal risk may be related to the use of oral contraceptive formulations containing lower hormonal doses of estrogens and progestogens.

8. CARBOHYDRATE AND LIPID METABOLIC EFFECTS

Oral contraceptives have been shown to impair oral glucose tolerance. Oral contraceptives containing greater than 0.075 mg of estrogen cause glucose intolerance with impaired insulin secretion, while lower doses of estrogen may produce less glucose intolerance. Progestogens increase insulin secretion and create insulin resistance, this effect varying with different progestational agents. However, in the non-diabetic woman, oral contraceptives appear to have no effect on fasting blood glucose. Because of these demonstrated effects, prediabetic and diabetic women should be carefully observed while taking oral contraceptives.

Some women may develop persistent hypertriglyceridemia while on the pill. As discussed earlier (see **WARNINGS**, sections 1a. and 1d.), changes in serum triglycerides and lipoprotein levels have been reported in oral contraceptive users.

9. ELEVATED BLOOD PRESSURE

An increase in blood pressure has been reported in women taking oral contraceptives. The incidence of risk also was reported to increase with continued use and among older women. Data from the Royal College of General Practitioners and subsequent randomized trials have shown that the incidence of hypertension increases with increasing concentrations of progestogens.

Women with a history of hypertension or hypertension-related diseases or renal disease should be encouraged to use another method of contraception. If women elect to use oral contraceptives, they should be monitored closely and if significant elevation of blood pressure occurs oral contraceptives should be discontinued. For most women, elevated blood pressure will return to normal after stopping oral contraceptives and there is no difference in the occurrence of hypertension among ever- and never-users.

10. HEADACHE

The onset or exacerbation of migraine or development of headache with a new pattern which is recurrent, persistent or severe requires discontinuation of oral contraceptives and evaluation of the cause.

11. BLEEDING IRREGULARITIES

Breakthrough bleeding and spotting are sometimes encountered in patients on oral contraceptives, especially during the first 3 months of use. Non-hormonal causes should be considered and adequate diagnostic measures taken to rule out malignancy or pregnancy in the event of breakthrough bleeding, as in the case of any abnormal vaginal bleeding. If pathology has been excluded, time or a change to another formulation may solve the problem. In the event of amenorrhea, pregnancy should be ruled out.

Some women may encounter post-pill amenorrhea or oligomenorrhea, especially when such a condition was pre-existent.

PRECAUTIONS

1. PHYSICAL EXAMINATION AND FOLLOW-UP

A complete medical history and physical examination should be taken prior to the initiation or reinstitution of oral contraceptives and at least annually during use of oral contraceptives. These physical examinations should include special reference to blood pressure, breasts, abdomen and pelvic organs, including cervical cytology and relevant laboratory tests. In case of undiagnosed, persistent or recurrent abnormal vaginal bleeding, appropriate diagnostic measures should be conducted to rule out malignancy. Women with a strong family history of breast cancer or who have breast nodules should be monitored with particular care.

2. LIPID DISORDERS

Women who are being treated for hyperlipidemias should be followed closely if they elect to use oral contraceptives. Some progestogens may elevate LDL levels and may render the control of hyperlipidemias more difficult.

3. LIVER FUNCTION

If jaundice develops in any woman receiving oral contraceptives the medication should be discontinued. Steroid hormones may be poorly metabolized in patients with impaired liver function.

4. FLUID RETENTION

Oral contraceptives may cause some degree of fluid retention. They should be prescribed with caution, and only with careful monitoring, in patients with conditions which might be aggravated by fluid retention.

5. EMOTIONAL DISORDERS

Women with a history of depression should be carefully observed and the drug discontinued if depression recurs to a serious degree.

6. CONTACT LENSES

Contact lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist.

7. DRUG INTERACTIONS

Reduced efficacy and increased incidence of breakthrough bleeding and menstrual irregularities have been associated with concomitant use of rifampin. A similar association though less marked, has been suggested with barbiturates, phenylbutazone, phenytoin sodium, and possibly with griseofulvin, ampicillin and tetracyclines.

8. INTERACTIONS WITH LABORATORY TESTS

Certain endocrine and liver function tests and blood components may be affected by oral contraceptives:

a. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3; increased norepinephrine-induced platelet aggregability.

b. Increased thyroid binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by protein-bound iodine (PBI), T4 by column or by radioimmunoassay. Free T3 resin uptake is decreased, reflecting the elevated TBG. Free T4 concentration is unaltered.

c. Other binding proteins may be elevated in serum.

d. Sex steroid binding globulins are increased and result in elevated levels of total circulating sex steroids and corticoids; however, free or biologically active levels remain unchanged.

e. Triglycerides may be increased.

f. Glucose tolerance may be decreased.

g. Serum folate levels may be depressed by oral contraceptive therapy. This may be of clinical significance if a woman becomes pregnant shortly after discontinuing oral contraceptives.

9. CARCINOGENESIS

See **WARNINGS** section.

10. PREGNANCY

Pregnancy Category X. See **CONTRAINDICATIONS** and **WARNINGS** sections.

11. NURSING MOTHERS

Small amounts of oral contraceptive steroids have been identified in the milk of nursing mothers and a few adverse effects on the child have been reported, including jaundice and breast enlargement. In addition, oral contraceptives given in the postpartum period may interfere with lactation by decreasing the quantity and quality of breast milk. If possible, the nursing mother should be advised not to use oral contraceptives but to use other forms of contraception until she has completely weaned her child.

INFORMATION FOR THE PATIENT

See **PATIENT LABELING.**

ADVERSE REACTIONS

An increased risk of the following serious adverse reactions has been associated with the use of oral contraceptives (see **WARNINGS** section): Thrombophlebitis • Arterial thromboembolism • Pulmonary embolism • Myocardial infarction • Cerebral hemorrhage • Cerebral thrombosis • Hypertension • Gallbladder disease • Hepatic adenomas, carcinomas or benign liver tumors

There is evidence of an association between the following conditions and the use of oral contraceptives, although additional confirmatory studies are needed: Mesenteric thrombosis • Retinal thrombosis

The following adverse reactions have been reported in patients receiving oral contraceptives and are believed to be drug-related: Nausea • Vomiting • Gastrointestinal symptoms (such as abdominal cramps and bloating) • Breakthrough bleeding • Spotting • Change in menstrual flow • Amenorrhea • Temporary infertility after discontinuation of treatment • Edema • Melasma which may persist • Breast changes: tenderness, enlargement, secretion • Change in weight (increase or decrease) • Change in cervical erosion and secretion • Diminution in lactation when given immediately postpartum • Cholestatic jaundice • Migraine • Rash (allergic) • Mental depression • Reduced tolerance to carbohydrates • Vaginal candidiasis • Change in corneal curvature (steepening) • Intolerance to contact lenses

The following adverse reactions have been reported in users of oral contraceptives and the association has been neither confirmed nor refuted: Pre-menstrual syndrome • Cataracts • Changes in appetite • Cystitis-like syndrome • Headache • Nervousness • Dizziness • Hirsutism • Loss of scalp hair • Erythema multiforme • Erythema nodosum • Hemorrhagic eruption • Vaginitis • Porphyria • Impaired renal function • Hemolytic uremic syndrome • Budd-Chiari syndrome • Acne • Changes in libido • Colitis

OVERDOSAGE

Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea, and withdrawal bleeding may occur in females.

NON-CONTRACEPTIVE HEALTH BENEFITS

The following non-contraceptive health benefits related to the use of oral contraceptives are supported by epidemiological studies which largely utilized oral contraceptive formulations containing estrogen doses exceeding 0.035 mg of ethinyl estradiol or 0.05 mg of mestranol.

Effects on menses: • Increased menstrual cycle regularity • Decreased blood loss and decreased incidence of iron deficiency anemia • Decreased incidence of dysmenorrhea

Effects related to inhibition of ovulation: • Decreased incidence of functional ovarian cysts • Decreased incidence of ectopic pregnancies

Effects from long-term use: • Decreased incidence of fibroadenomas and fibrocystic disease of the breast • Decreased incidence of acute pelvic inflammatory disease • Decreased incidence of endometrial cancer • Decreased incidence of ovarian cancer

Direct inhibition of proteases and cervical plasminogen activator by antibiotics 606
Ariel Milwidsky, MD, Zvezdana Finci-Yeheskel, MSc, and Michael Mayer, DSc
Jerusalem, Israel

The ability of several antibiotics to prevent premature rupture of the membranes may be related to their capacity to exert direct inhibition on several proteases.

The effect of fetal sepsis on umbilical cord blood gases 612
Bruce A. Meyer, MD, Jan E. Dickinson, MD, Charles Chambers, MD, and Valerie M. Parisi, MD, MPH
Houston, Texas

Fetal sepsis at term is associated with a deterioration in the fetal acid-base status and a prolongation of labor.

Eradication of *Ureaplasma urealyticum* from the amniotic fluid with transplacental antibiotic treatment 618
Roberto Romero, MD, Zion Hagay, MD, Jose Nores, MD, Waldo Sepulveda, MD, and Moshe Mazor, MD
New Haven, Connecticut, and Detroit, Michigan

Ureaplasma urealyticum was eradicated from the amniotic cavity of a patient with premature rupture of membranes at 24 weeks with erythromycin treatment.

Vaginal Po_2 in healthy women and in women infected with *Trichomonas vaginalis*: Potential implications for metronidazole therapy 620
Abdel L. Rashad, MD, PhD, William L. Toffler, MD, Nina Wolf, RN, Kent Thornburg, PhD, E. Paul Kirk, MD, Gene Ellis, AAS, RRT, and W.E. Whitehead, BS
Portland, Oregon

Measurement of vaginal Po_2 in healthy women and trichomoniasis patients demonstrated an anaerobic or microaerophilic environment, which is known to enhance biologic activity of metronidazole.

Immunoreactive circulating endothelin-1 in normal and hypertensive pregnancies 624
Eyal Schiff, MD, Gilad Ben-Baruch, MD, Edna Peleg, PhD, Talma Rosenthal, MD, Menachem Alcalay, MD, Michal Devir, MD, and Shlomo Mashiach, MD
Tel-Hashomer, Israel

Relatively high levels of endothelin-1 were found in the sera of women with preeclampsia compared with those of nonhypertensive and chronically hypertensive pregnant women.

Platelet activation and vascular damage in gestational hypertension 629
Veronique C. Ballegeer, MD, Bernard Spitz, MD, PhD, Luc A. De Baene, MD, Andre F. Van Assche, MD, PhD, Melanie Hidajat, MD, and Arnold M. Criel, MD
Brugge and Leuven, Belgium

Indexes of endothelial damage and platelet activation antedate parameters of coagulation and the clinical onset of symptoms in gestational hypertension.

Human monoclonal antibody recognizing an antigen associated with ovarian and other adenocarcinomas 634

Lloyd H. Smith, MD, PhD, Amy Yin, MD, Michelle S. Glasky, PhD, Nancy Tyler, PhD, Mariana Robles, MS, Chris A. Foster, BS, Marcia Bieber, MD, and Nelson N.H. Teng, MD, PhD

Davis and Stanford, California

An antigen recognized by MS2B6, a human immunoglobulin M monoclonal antibody, is widely distributed among ovarian and other adenocarcinomas; its characteristics and cellular location are presented.

A randomized, placebo-controlled trial of betamethasone for the prevention of respiratory distress syndrome at 24 to 28 weeks' gestation 646

Thomas J. Garite, MD, Pamela J. Rumney, RNC, Gerald G. Briggs, BPharm, James A. Harding, MD, Michael P. Nageotte, MD, Craig V. Towers, MD, and Roger K. Freeman, MD

Long Beach and Orange, California

A randomized trial of maternal corticosteroids in patients at <28 weeks' gestation failed to reveal any reduction in the incidence of neonatal respiratory distress syndrome.

Gonadotropin and ovarian hormone dynamics in luteal phase defects 652

Sam E. Alexander, MD, Sezer Aksel, MD, Richard R. Yeoman, PhD, and Julianne M. Hazelton, BS

Mobile, Alabama

Levels of periovulatory and luteal phase gonadotropin immunoreactivity and bioactivity are normal in luteal-phase defect cycles.

Serial thoracic versus abdominal circumference ratios for the prediction of pulmonary hypoplasia in premature rupture of the membranes remote from term 658

M. D'Alton, MD, B. Mercer, MD, E. Riddick, MD, and D. Dudley, MD

Boston, Massachusetts, Memphis, Tennessee, and Ottawa, Ontario, Canada

Serial measurement of the fetal thoracic/abdominal ratio reliably predicts pulmonary hypoplasia in patients with premature rupture of the membranes that occurs before 26 weeks' gestation.

Triplet pregnancy involving complete hydatidiform mole and two fetuses: Genetic analysis by deoxyribonucleic acid fingerprint 664

Chihiro Azuma, MD, DMSci, Fumitaka Saji, MD, DMSci, Masahiko Takemura, MD, Kazutomo Ohashi, MD, Tadashi Kimura, MD, Akira Miyake, MD, DMSci, Tetsu Takagi, MD, DMSci, and Osamu Tanizawa, MD, DMSci

Osaka, Japan

The zygosity of fetuses and differential diagnosis of trophoblastic tumor can be performed by DNA fingerprint analysis in triplet pregnancy involving complete mole.

Contents

Influence of alcohol intake on postoperative morbidity after hysterectomy 667
Christine Felding, MD, Lars M. Jensen, MD, and Hanne Tønnesen, MD
Copenhagen, Denmark

In a prospective study the postoperative complications after hysterectomy were registered and the effect on the morbidity of alcohol abuse was assessed.

BASIC SCIENCE SECTION

Effects of β-hydroxybutyrate infusion on hind limb metabolism in fetal sheep 671
Jane E. Harding, MB, ChB, DPhil, Valerie E. Charlton, MD, and Pandora C. Evans, MSc
Auckland, New Zealand, and San Francisco, California

β-Hydroxybutyrate is taken up by the hind limb of the fetal sheep as a substitute for glucose, resulting in lactate production.

Regulation of growth of normal ovarian epithelial cells and ovarian cancer cell lines by transforming growth factor-β 676
Andrew Berchuck, MD, Gus Rodriguez, MD, George Olt, MD, Regina Whitaker, BS, Matthew P. Boente, MD, Bradley A. Arrick, MD, Daniel L. Clarke-Pearson, MD, and Robert C. Bast, Jr., MD
Durham, North Carolina, and South San Francisco, California

Transforming growth factor-β inhibits proliferation of normal ovarian epithelial cells, whereas some ovarian cancer cell lines are resistant to this growth inhibitor.

Prostaglandin- or endothelium-mediated vasodilation is not involved in the blunted responses of blood vessels to vasoconstrictors in pregnant rats 684
Jean St-Louis, PhD, and Benoit Sicotte, BSc
Montreal, Quebec, Canada

It is reported that endogenous prostaglandins or EDRF are not involved in the blunted aortic responses to phenylephrine during gestation in the rat.

Inhibition of preimplantation mouse embryo development by isoflurane 693
Joe R. Warren, PhD, Barry Shaw, MD, and Michael P. Steinkampf, MD
Birmingham, Alabama

Isoflurane adversely affects subsequent preimplantation development when two-cell mouse embryos are exposed just before the onset of their first cleavage in vitro.

Venous drainage of the human uterus: Respiratory gas studies in? normal and fetal growth-retarded pregnancies 699
Giorgio Pardi, MD, Irene Cetin, MD, Anna Maria Marconi, MD, Patrizia Bozzetti, MD, Mauro Buscaglia, MD, Edgar L. Makowski, MD, and Frederick C. Battaglia, MD
Milan, Italy, and Denver, Colorado

The human placenta simulates a relatively inefficient venous equilibrator with significant differences between normal and growth-retarded human pregnancies.

Long-term acid-base measurements in the fetal and maternal baboon 707
Salha S. Daniel, PhD, L. Stanley James, MD, Gregory MacCarter, MA, Hisayo O. Morishima, MD, PhD, and Raymond I. Stark, MD
New York, New York

Baseline pHa in the baboon fetus is higher, whereas $PaCO_2$ is lower than those reported in humans; however, maternal-fetal gradients are comparable.

The effects of glycemia on breathing movements and plasma prostaglandin E concentrations in the sheep fetus 713
A.L. Fowden, PhD, S. Thian, BA, M. Silver, PhD, M.M. Ralph, PhD, and R. Harding, PhD
Cambridge, England, and Clayton, Victoria, Australia

Maintaining fetal normoglycemia during maternal fasting prevents the fall in fetal respiratory activity but not the increase in plasma prostaglandin E concentration in fetal sheep.

Human vaginal leukocytes and the effects of vaginal fluid on lymphocyte and macrophage defense functions 720
Joseph A. Hill, MD, and Deborah J. Anderson, PhD
Boston, Massachusetts

The presence and activity of lymphocytes and macrophages in the human vagina have been further defined; nonoxynol 9 is toxic to lymphocytes and macrophages.

Effect of endothelium-derived relaxing factor inhibition on the umbilical-placental circulation in fetal lambs in utero 727
Jia-Kan Chang, MD, Christine Roman, BS, and Michael A. Heymann, MD
Taipei, Taiwan, and San Francisco, California

Umbilical-placental vascular resistance in intact fetal lambs is, at least in part, regulated by local production of endothelium-derived relaxing factor.

SYMPOSIUM ON GnRH ANALOGS: OPTIMAL MANAGEMENT STRATEGIES

Nafarelin in the management of endometriosis: Quality of life assessment 735
Kenneth A. Burry, MD
Portland, Oregon

Nafarelin and danazol demonstrate equal efficacy in the treatment of endometriosis, but the safety and quality of life profiles of nafarelin and danazol differ.

Hormone treatment of endometriosis: The estrogen threshold hypothesis 740
Robert L. Barbieri, MD
Stony Brook, New York

This is an overview of different treatment strategies for endometriosis with gonadotropin-releasing hormone agonists that may avoid some of the menopausal symptoms associated with therapy.

Contents

Treatment of uterine fibroids: Current findings with gonadotropin-releasing hormone agonists 746
G. David Adamson, MD
Palo Alto, California

The rationale and management strategies for the use of gonadotropin-releasing hormone agonists for the treatment of uterine fibroids are discussed.

Gonadotropin-releasing hormone agonists: Strategies for managing the hypoestrogenic effects of therapy 752
Howard L. Judd, MD
Los Angeles, California

Regimens that combine a gonadotropin-releasing hormone agonist with a progestin may enhance the clinical usefulness of gonadotropin-releasing hormone agonists for the treatment of endometriosis and other conditions.

Gonadotropin-releasing hormone analogs: Update on new findings 757
Milan R. Henzl, MD
Palo Alto, California

This reviews current studies of nasal absorption, efficacy and safety of retreatment, and therapeutic strategies for the prevention of hypoestrogenic effects with nafarelin.

Bioavailability of nafarelin in healthy volunteers 762
Melvin D. Chaplin, PhD
Palo Alto, California

Intranasal nafarelin is reliably absorbed in healthy volunteers, although the absolute bioavailability is low.

Make researching easier with the Ten-Year Cumulative Index (1978-1987) to the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY

The Ten-Year Cumulative Index is a complete guide to more than 30,000 pages of original articles, case reports, letters, and editorials published in the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY from 1978 through 1987 (volumes 130 to 157). Numbering more than 800 pages, the Cumulative Index includes both a subject and an author index. This hard-cover volume is $64.50 ($69.00 international). Prices include shipping. *Payment must accompany all orders and must be in U.S. funds, drawn on a U.S. bank.*

Contact Mosby–Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318 USA; phone (314) 453-4394. In the U.S., call toll-free: 1-800-325-4177, ext. 4394. Please allow six weeks for delivery.

The JOURNAL is abstracted and/or indexed in *Index Medicus, Science Citation Index, Current Contents/Clinical Medicine, Current Contents/Life Sciences, Excerpta Medica, BRS Colleague,* and MEDLINE.

Authorization to photocopy items for internal or personal use is granted by Mosby–Year Book, Inc., for libraries and other users registered with the Copyright Clearance Center (CCC) Transactional Reporting Service, provided that 10¢ per page per copy is paid directly to CCC, 27 Congress St., Salem, MA 01970; phone (508)744-3350. The U.S. Government retains a nonexclusive, royalty-free license in and to any copyright on articles authored by government employees. 0002-9378/92 $00.00 + .10.

You think it's good medicine.

She thinks it's wonderful.

Thanks to you and Premarin®, she could make these years the best years of her life

Hot flashes–Now part of the past for millions of women
Premarin® can dramatically reduce the incidence of hot flashes, night sweats, and related sleep disturbances.

Osteoporosis–No longer part of the future for many women
Premarin® is the first estrogen product proven to prevent postmenopausal osteoporosis in women at risk. And it's the *only* estrogen product proven in studies to reduce the risk of osteoporosis-related fractures by as much as 62%.[1]

Contraindications

Estrogens should not be used in women (or men) with any of the following conditions: known or suspected 1) pregnancy, 2) breast cancer, 3) estrogen-dependent neoplasia, 4) undiagnosed abnormal genital bleeding, 5) active thrombophlebitis or thromboembolic disorders.

Note: Estrogens have been reported to increase the risk of endometrial carcinoma in postmenopausal women.

Nothing else is

PREMARIN®

(conjugated estrogens tablets)

The appearance of this tablet is a trademark of Wyeth-Ayerst Laboratories.

Please see brief summary of prescribing information on last page of this advertisement.

BRIEF SUMMARY *(FOR FULL PRESCRIBING INFORMATION AND PATIENT INFORMATION, SEE PACKAGE CIRCULARS.)*

PREMARIN® Brand of conjugated estrogens tablets, USP
PREMARIN® Brand of conjugated estrogens Vaginal Cream, in a nonliquefying base

1. ESTROGENS HAVE BEEN REPORTED TO INCREASE THE RISK OF ENDOMETRIAL CARCINOMA. Close clinical surveillance of all women taking estrogens is important. Adequate diagnostic measures including endometrial sampling when indicated should be undertaken to rule out malignancy in all cases of undiagnosed persistent or recurring abnormal vaginal bleeding. There is currently no evidence that "natural" estrogens are more or less hazardous than "synthetic" estrogens at equiestrogenic doses.
2. ESTROGENS SHOULD NOT BE USED DURING PREGNANCY.
Estrogen therapy during pregnancy is associated with an increased risk of congenital defects in the reproductive organs of the male and female fetus, an increased risk of vaginal adenosis, squamous-cell dysplasia of the uterine cervix, and vaginal cancer in the female later in life. The 1985 DES Task Force concluded that women who used DES during their pregnancies may subsequently experience an increased risk of breast cancer. However, a causal relationship is still unproven, and the observed level of risk is similar to that for a number of other breast cancer risk factors.
There is no indication for estrogen therapy during pregnancy. Estrogens are ineffective for the prevention or treatment of threatened or habitual abortion.

DESCRIPTION: PREMARIN (conjugated estrogens, USP) contains a mixture of estrogens, obtained exclusively from natural sources, blended to represent the average composition of material derived from pregnant mares' urine. It contains estrone, equilin, and 17α-dihydroequilin, together with smaller amounts of 17α-estradiol, equilenin, and 17α-dihydroequilenin as salts of their sulfate esters. Tablets are available in 0.3 mg, 0.625 mg, 0.9 mg, 1.25 mg, and 2.5 mg strengths of conjugated estrogens. Cream is available as 0.625 mg conjugated estrogens per gram.

INDICATIONS AND USAGE: Moderate-to-severe vasomotor symptoms associated with the menopause. (There is no evidence that estrogens are effective for nervous symptoms or depression which might occur during menopause and they should not be used to treat these conditions.) Prevention and management of osteoporosis (abnormally low bone mass). Atrophic vaginitis. Atrophic urethritis. Hypoestrogenism due to hypogonadism, castration or primary ovarian failure.

PREMARIN (conjugated estrogens) Vaginal Cream is indicated in the treatment of atrophic vaginitis and kraurosis vulvae.

PREMARIN HAS NOT BEEN SHOWN TO BE EFFECTIVE FOR ANY PURPOSE DURING PREGNANCY AND ITS USE MAY CAUSE SEVERE HARM TO THE FETUS (SEE BOXED WARNING).

CONTRAINDICATIONS: Estrogens should not be used in women (or men) with any of the following conditions: 1. Known or suspected pregnancy (see Boxed Warning). 2. Known or suspected cancer of the breast except in appropriately selected patients being treated for metastatic disease. 3. Known or suspected estrogen-dependent neoplasia. 4. Undiagnosed abnormal genital bleeding. 5. Active thrombophlebitis or thromboembolic disorders. 6. Estrogen replacement therapy has not been reported to increase the risk of thrombophlebitis and/or thromboembolic disease. However, there is insufficient information regarding women who have had previous thromboembolic disease.

PREMARIN Tablets and Vaginal Cream should not be used in patients hypersensitive to their ingredients.

WARNINGS: Some studies suggest a possible increased incidence of breast cancer in women taking higher doses of estrogen for prolonged time periods. The majority of studies have not shown an association with usual estrogen replacement doses. Endometrial cancer risk among estrogen users was about 4-fold or greater than in non-users, and appears dependent on treatment duration and estrogen dose. In patients on combined estrogen-progestin therapy, this risk appears to be decreased. (See PRECAUTIONS below.)

Estrogen therapy during pregnancy is associated with an increased risk of fetal congenital reproductive tract disorders.

A 2.5-fold increase in the risk of surgically confirmed gall bladder disease in women receiving postmenopausal estrogens has been reported.

Large doses of estrogen such as those used to treat prostate and breast cancer have been shown to increase the risk of non-fatal myocardial infarction, pulmonary embolism, and thrombophlebitis in men. This cannot necessarily be extrapolated to women. However, to avoid theoretical cardiovascular risk caused by high estrogen doses, the doses for estrogen replacement therapy should not exceed the recommended dose.

Blood pressure should be monitored with estrogen use, especially if high doses are used.

Estrogens may lead to severe hypercalcemia in patients with breast cancer and bone metastases.

PRECAUTIONS: The addition of a progestin for 7 or more days of a cycle of estrogen administration reportedly lowers the incidence of endometrial hyperplasia. Studies of endometrium suggest that 10 to 13 days of progestin are needed to provide maximal endometrial maturation and elimination of hyperplastic changes. Additional risks, such as adverse effects on carbohydrate and lipid metabolism, may be associated with the inclusion of progestin in estrogen replacement regimens. The choice of progestin and dosage may be important in minimizing these adverse effects.

Physical examination and a complete medical and family history should be taken prior to the initiation of any estrogen therapy with special reference to blood pressure, breasts, abdomen, and pelvic organs, and should include a Papanicolaou smear. As a general rule, estrogen should not be prescribed for longer than one year without another physical examination being performed. Conditions influenced by fluid retention, such as asthma, epilepsy, migraine, and cardiac or renal dysfunction, require careful observation. Certain patients may develop manifestations of excessive estrogenic stimulation, such as abnormal or excessive uterine bleeding and mastodynia. Pre-existing uterine leiomyomata may increase in size during estrogen use. Estrogens should be used with care in patients with impaired liver function, renal insufficiency, or metabolic bone diseases associated with hypercalcemia.

The following drug/laboratory test interactions have been reported, some only with estrogen-progestin combinations (oral contraceptives):

1. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3; increased norepinephrine-induced platelet aggregability.
2. Increased thyroid binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by T_4 levels determined by column or by radioimmunoassay. Free T_3 resin uptake is decreased, reflecting the elevated TBG; free T_4 concentration is unaltered.
3. Impaired glucose tolerance.
4. Reduced response to metyrapone test.
5. Reduced serum folate concentration.

MUTAGENESIS AND CARCINOGENESIS: Long-term, continuous administration of natural and synthetic estrogens in certain animal species increases the frequency of carcinomas of the breast, cervix, vagina, and liver.

PREGNANCY CATEGORY X: Estrogens should not be used during pregnancy. See **CONTRAINDICATIONS** and Boxed Warning.

NURSING MOTHERS: As a general principle, the administration of any drug to nursing mothers should be done only when clearly necessary since many drugs are excreted in human milk.

ADVERSE REACTIONS: The following have been reported with estrogenic therapy: changes in vaginal bleeding pattern and abnormal withdrawal bleeding or flow, breakthrough bleeding, spotting, increase in size of uterine fibromyomata, vaginal candidiasis, change in amount of cervical secretion; tenderness or enlargement of breasts; nausea, vomiting, abdominal cramps, bloating, cholestatic jaundice; chloasma or melasma that may persist when drug is discontinued, erythema multiforme, erythema nodosum, hemorrhagic eruption, loss of scalp hair, hirsutism; steepening of corneal curvature, intolerance to contact lenses; headache, migraine, dizziness, mental depression, chorea; increase or decrease in weight; reduced carbohydrate tolerance; aggravation of porphyria; edema; changes in libido.

ACUTE OVERDOSAGE: May cause nausea and vomiting.

DOSAGE AND ADMINISTRATION:

PREMARIN® Brand of conjugated estrogens tablets, USP

1. *Given cyclically for short-term use only.* For treatment of moderate-to-severe vasomotor symptoms, atrophic vaginitis, or atrophic urethritis associated with the menopause (0.3 mg to 1.25 mg or more daily). The lowest dose that will control symptoms should be chosen and medication should be discontinued as promptly as possible. Administration should be cyclic (eg, three weeks on and one week off). Attempts to discontinue or taper medication should be made at three- to six-month intervals.
2. *Given cyclically:* Hypoestrogenism. Osteoporosis.

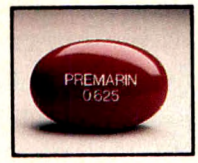
Hypoestrogenism due to: Female hypogonadism—2.5 mg to 7.5 mg daily in divided doses for 20 days followed by 10 day rest period. If bleeding does not occur by the end of this period, the same dosage schedule is repeated. Female castration or primary ovarian failure—1.25 mg daily, cyclically. Adjust upward or downward according to response of the patient. For maintenance, adjust dosage to lowest level that will provide effective control.

Osteoporosis—0.625 mg daily. Administration should be cyclic (eg, three weeks on and one week off).

PREMARIN® Brand of conjugated estrogens Vaginal Cream

Given cyclically for short-term use only. For treatment of atrophic vaginitis or kraurosis vulvae.

The lowest dose that will control symptoms should be chosen and medication should be discontinued as promptly as possible.



Attempts to discontinue or taper medication should be made at three- to six-month intervals.

Usual dosage range: 2 g to 4 g daily, intravaginally, depending on the severity of the condition.

Patients with an intact uterus who are treated with either PREMARIN Tablets or Vaginal Cream should be monitored for signs of endometrial cancer and appropriate measures taken to rule out malignancy in the event of persistent or recurring abnormal vaginal bleeding.

Revised August 21, 1989

INFORMATION FOR AUTHORS

Editorial policies

The requirements for manuscripts submitted to the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY conform to the "Uniform Requirements for Manuscripts Submitted to Biomedical Journals" established by the International Committee of Medical Journal Editors (N Engl J Med 1991;324:424-8). Certain requirements unique to our JOURNAL are provided in Information for Authors, published in each issue of the JOURNAL.

Manuscript submission. Manuscripts should be submitted to one of the two Editors in Chief as follows:

1. **Dr. Zuspan**—manuscripts from the eastern and southeastern United States and from England, Israel, and Italy, manuscripts written for Clinical Opinion and Current Development, Letters to the Editors, and all manuscripts presented before one of the official sponsoring societies, except the Society for Gynecologic Investigation. *Manuscripts from The Society of Perinatal Obstetricians should be submitted to Dr. J. Peter Van Dorsten, P.O. Box 34, MCV Station, Richmond, VA 23298.*
2. **Dr. Quilligan**—manuscripts from states west of Pennsylvania, West Virginia, Kentucky, Tennessee, and Mississippi; manuscripts from Hawaii, Alaska, Canada, and abroad (except England, Israel, and Italy). Dr. Quilligan is responsible for manuscripts from the Society for Gynecologic Investigation. *Manuscripts from the Society for Gynecologic Investigation should be submitted to Dr. Roger A. Lobo, Women's Hospital, 1240 North Mission Road, Room 1M2, Los Angeles, CA 90033.*

Author's suggested reviewers. When authors submit their manuscripts, they must provide the names and addresses of at least three reviewers for consideration by the Editors.

Copyright statement. The specified copyright statement that follows the Information for Authors in each issue of the JOURNAL must be completed, signed by all authors, and submitted with the manuscript. If not completed in full, it will be returned to the author for completion. The copyright statement and checklist form may be torn from the JOURNAL or photocopied for submission.

Checklist. The checklist that appears with the copyright statement in each issue of the JOURNAL must be fully completed by the author(s) and sent with each submitted manuscript. A more complete description of each item that must be checked is provided under the appropriate heading in the Information for Authors, which is published in each issue of the JOURNAL. *If the checklist is not completed in full, the deficiencies will be noted, and the form, as well as the manuscript when necessary, will be returned to the author for completion.*

Previous publication. If a report by the same author(s) or some of the same authors has been previously published in any medium that deals in any respect whatsoever with the same patients, same animals, same laboratory experiments, or same data, in part or in full, as those reported in the manuscript being submitted, two reprints of the article(s) or two copies of the manuscript, be it a full-length report or an abstract, must be submitted with the manuscript. Two copies of a new manuscript being prepared for possible publication also must be submitted. The author(s) should inform the Editor of the circumstances, similarities, and differences of the reports. This requirement also applies to the submission of a manuscript in which a few different patients, animals, laboratory experiments, or data were added to those reported in a previous publication or in a submitted or accepted manuscript. Articles previously published in another language will not be considered.

Human and nonhuman experimentation. It is assumed by the Editors that manuscripts emanating from a particular institution are submitted with the approval of the

requisite authority. Human experimentation that requires local institutional approval must have this approval *before the experiment is started* and approval must be so indicated in the *Material and Methods* section of the submitted manuscript. Reports of experiments on nonhuman animals or other species must *state in the* Material and Methods *section of the manuscript* that the guidelines for the care and use of the animals *approved by the local institution* were followed. The type of nonhuman animals or other species used in an investigation must be named in the title, abstract, key words, and *Material and Methods* section of the manuscript.

Authorship. For manuscripts with two or more authors, each author must qualify by having participated actively and sufficiently in the study that is being performed and reported. The inclusion of each author in the authorship list of a report is based only (1) on substantial contributions to (a) concept and design, or analysis and interpretation of data and (b) drafting the manuscript or revising it critically for important intellectual content; and (2) on final approval by each author of the version of the manuscript. Conditions 1 (a and b) and 2 must both be met. Others contributing to the work should be recognized separately in an Acknowledgment. *In the covering letter that accompanies the submitted manuscript, it must be confirmed that all authors fulfilled both conditions.*

Conflict of interest. Authors are expected to inform the Editor, in a letter accompanying the submitted manuscript, of any commercial association that might pose a conflict of interest, such as ownership, stock holdings, equity interests and consultant activities, or patent-licensing situations. Such information is confidential, is not given to the consultants, and does not play a part in the decision of the quality or timeliness of the manuscript. If the manuscript is accepted, the author and the Editor will determine how best to release the information. The usual and customary listing of sources of support and institutional affiliations on the title page is proper and does not imply a conflict of interest; only where there is a possible conflict of interest is the author(s) expected to inform the Editor.

Disclaimer. Statements and opinions expressed in articles and communications herein are those of the author(s) and not necessarily those of the Editor(s) or Publisher, and the Editor(s) and Publisher disclaim any responsibility or liability for such material. Neither the Editor(s) nor the Publisher guarantees, warrants, or endorses any product or service advertised in this publication, nor do they guarantee any claim made by the manufacturer of such product or service.

General requirements for preparation of manuscripts

The original and two good-quality photocopies of the manuscript and three sets of black-and-white glossy prints of illustrations are required. See "Color figures" and "Computer-generated figures" for special requirements. Manuscripts must be submitted in English.

Manuscripts must be typed double-spaced on one side only of 22 × 28 cm (8½ × 11 inch) white bond paper with 1-inch margins at top, bottom, and sides. Number pages consecutively in the upper right-hand corner in the following order: title page, condensation, abstract, body of text, acknowledgments, references, figure legends, and tables.

Title page. The title page (page 1) should contain in sequence the title (concise and suitable for indexing purposes); author line with first name, middle initial, and last name of each author and each author's highest academic degree (both MD and PhD are acceptable, but honors degrees are not permitted); city(ies), state(s) in which the study was conducted; divisional, or departmental, and institutional affiliations at the time the study was performed; source(s) of financial support; presented line, if applicable; disclaimers, if any; name, address, business and home telephone numbers, and fax number of author to whom requests for reprints should be addressed (if reprints will not be available, it should be so stated); and name, address, business and home telephone numbers, and fax number of author responsible for correspondence concerning the manuscript if different from author to whom reprint requests are addressed. *At the bottom of the title page supply a short title for the running head not exceeding 52 characters (including word spaces).*

Condensation. On page 2 of the manuscript provide a brief, concise condensation, typed double-spaced, that will appear with the title in publication of the Contents pages of the JOURNAL. It should be a single sentence, limited to a maximum of 25 words, delineating the essential point(s) made in the manuscript.

Abstract page including key words/phrases. On manuscript page 3, type the abstract, double-spaced, with the required margins and headed by the title of the article and name(s) of author(s). Below the abstract, list 3 to 5 *key words or short phrases* for indexing purposes.

A structured abstract is required for certain types of articles and a *standard abstract format* is required for other types of articles; therefore the author(s) should select and prepare the appropriate abstract to be used in the submitted manuscript. This applies to both independently submitted and society manuscripts.

Structured abstract. A structured abstract, limited to 150 words, is to be used for regular articles, society articles, and Current Investigation articles; excluded are Clinical Opinion, Current Development, case report, and brief communication articles. The structured abstract is to contain the following major headings: *Objective(s); Study Design; Results;* and *Conclusion(s).* The *Objective(s)* reflects the purpose of the study, that is, the hypothesis that is being tested. The *Study Design* should include the setting for the study, the subjects (number and type), the treatment or intervention, and the type of statistical analysis. The *Results* include the outcome of the study and statistical significance if appropriate. The *Conclusion(s)* states the significance of the results.

Standard abstract. The standard abstract format is required for Clinical Opinion, Current Development, case report, and brief communication articles. The standard abstracts for Clinical Opinion and Current Development articles are to be 50 to 150 words and standard abstracts for case reports and brief communications are limited to 50 words. Even though the formal names of these four types of articles are not used, an author should determine his/her type of manuscript and prepare the appropriate standard abstract, regardless of whether it is to be submitted independently or as a part of a society's transactions.

Text. Do not hesitate to write your manuscript in the first person and active voice if they are more appropriate to the information you wish to convey. The passive voice is generally more effective for describing techniques or observations, since the emphasis is on the "action" rather than on the person performing the action.

Only standard abbreviations are to be used. Consult the

Estimating length of manuscripts

With the exception of Current Development articles, the length of text material (introduction through *Comment* section) in regular manuscripts accepted for publication normally ranges from 750 to 4200 words (an average of 2000 words). A text of 4200 words or more can seldom be accepted, especially if tables and figures are included. The average manuscript of 2000 words of text with abstract, 3 tables with captions, 2 figures with legends, and references makes a 5.7-page article in the JOURNAL. The 2000 words of text alone makes approximately 8 pages of manuscript typed double-spaced with the required 1-inch margins (approximately 250 words per page). A table or figure that occupies both columns of half a JOURNAL page is equivalent to approximately 500 words in manuscript. Thus, if a greater number of illustrations and tables is used, the length of the text should be adjusted accordingly.

Council of Biology Editors Style Manual or the AMA's *Manual of Style.* Abbreviations in the title are not acceptable. They should be avoided, if possible, in the abstract. In the text they should be kept to a practical minimum. The full term for which an abbreviation stands should precede its first use in the text unless it is a standard unit of measurement.

Either the generic, chemical, or proprietary names of drugs may be used. If the generic or chemical name is used, authors may, if they desire, insert the proprietary name in parentheses after the first mention in the text, with the name of the manufacturer and city and state.

Regular articles are customarily organized into the following sections: an introduction and headings that identify *Material and Methods*, *Results*, and *Comment*. Authors may wish to summarize their findings in a short paragraph at the end of the *Comment* section. This format may not be appropriate for some types of articles.

In the introduction, state concisely the purpose and rationale for the study and cite only the most pertinent references as background.

In the *Material and Methods* section describe briefly (but in sufficient detail to permit other workers to repeat the study) the plan, the patients, experimental animals or other species, material, and controls, the methods and procedures utilized, and the statistical method(s) employed.

In the *Results* section present the detailed findings. Include mentions of all tables and/or figures. Figures and tables should supplement, not duplicate, the text; presentation of data in either one or the other will suffice. Emphasize only your important observations; do not compare your observations with those of others. Such comparisons and comments are reserved for the *Comment* section.

In the *Comment* section state the importance and significance of your findings but do not repeat the details given in the *Results* section. Limit your opinions to those strictly indicated by the facts in your report. Compare your findings with those of others. No new data should be presented in this section.

Acknowledgments. Acknowledge only persons who have made substantive contributions to the study.

References. A reasonable number (25) is allowed, except in case reports and brief communications (limited to 2) and in manuscripts for the Current Development section (for which there is no limit). Number references consecutively in the order in which they are mentioned in the text. Use the format of the "Uniform Requirements for Manuscripts Submitted to Biomedical Journals" (Vancouver style) (N Engl J Med 1991;324:424-8). Journal titles should conform to abbreviations used in *Cumulated Index Medicus.*

Examples (if six or fewer authors, list all; if seven or more authors, list three then et al.):

JOURNAL: Flamm BL, Dunnett C, Fischermann E, Quilligan EJ. Vaginal delivery following cesarean section: use of oxytocin augmentation and epidural anesthesia with internal tocodynamic and internal fetal monitoring. AM J OBSTET GYNECOL 1984;148:759-63.

BOOKS: Ledger WJ. Dystocia and prolonged labor. In: Wilson JR, Carrington ER, eds. Obstetrics and gynecology. St. Louis: CV Mosby, 1987 vol 8:474-93.

Personal communications and unpublished data, if essential, may be used but not as numbered references. If they are used, they are to be referred to, within parentheses, at the appropriate location in the text. If used, the author(s) must obtain written and signed permission for their use from the individual being quoted. *This signed permission must accompany the manuscript when it is submitted to the Editor.* Published abstracts can be used as numbered references; however, reference to the complete published article is preferred.

Figures. The term *figure* includes all types of illustrations such as graphs, diagrams, photographs, flow charts, and line drawings. A reasonable number of figures will be reproduced without charge, but special arrangements must be made with the Editors for color figures at an additional charge to the author. The quoted charge is per page of color, and as many as eight color figures can be included on one page if the color balance is appropriate.

Figures must be cited consecutively in the text in Arabic numerals and identified with a gummed label on the back of the figure with author(s) name(s), title of article, figure number, and top marked clearly. Consistency in size within the article is strongly preferred. Any special instructions regarding sizing should be clearly noted. Do not use paper clips or mar the surface of figures in any way. Figures will be returned only on request by the author.

For *black-and-white figures,* submit three sets of 3 × 4 inch (minimum) to 5 × 7 inch (maximum) unmounted, glossy prints. All lettering must be done with commercially available paste-on letters (or numbers) or by a professional; typed or freehand lettering is not acceptable. All lettering must be in proportion to the drawing, graph, or photograph. Original drawings, appropriately done in black India ink, roentgenograms, and other material must be submitted as glossy prints with good black-and-white contrast.

For *color figures* submit original transparencies and two sets of unmounted prints on glossy (smooth surface) paper. Polaroid prints are not acceptable. Color transparencies must have a color balance (consistency in lighting and film speed) that is acceptable to the author and Editors before acceptance for publication. Please note that 35 mm transparencies are enlarged to twice their original size. If it is important to deviate from this standard, please so indicate when the material is submitted. The top, first author's last name, and figure number must be indicated on the front of each transparency and the back of each print.

Computer-generated figures must be legible and clearly printed in jet black ink on heavy coated paper with either a glossy or dull finish. Any patterns or shadings must be dark enough for reproduction and must be distinguishable from each other. Lines, symbols, and letters should be both smooth and complete. The legend should not appear on the figure. On the back of each figure the name of the first author and the figure number should be given and the top indicated. Three original individual laser or plotter prints are to be submitted *unmounted* with the manuscript. Laser prints should be full size at 300 dots per inch (DPI) or greater full-page resolution; multiple illustrations on a page cannot be accepted. Dot matrix prints and photographic halftones are not acceptable. *Color figures* are acceptable, but special arrangements must be made with the Editors. The colors used must be dark enough and of sufficient contrast for reproduction. With the exception of fluorescent colors, all colors can be reproduced in four-color figures.The preparation and submitting of color prints should follow the preceding guidelines for black-and-white computer-generated illustrations.

Legends to figures. Legends for all figures must be typed together in numeric order double-spaced on one sheet of paper (or more if necessary) separate from the text of the manuscript. This page must be numbered in sequence after the references. Titles should be included in the legend, not on the print. Original magnifications should be provided. If a figure has been taken from copyrighted material, the legend must give full credit to the original source.

Tables. Tables should be typed on separate sheets of paper, one table to a page, and included at the end of the text. They should be numbered in Roman numerals. Each table must be cited in sequence at an appropriate point in the text. Titles should be brief yet indicate clearly the purpose or content of each table, and each column should be precisely defined by headings. Abbreviations and special designations should be explained in a footnote to the table. If a table or any part thereof has been taken from copyrighted material, a footnote to the table must give full credit to the original source. Arrangements must be made with the Editors for elaborate tables because of space limitations.

Permissions. Direct quotations, tables, or figures that have appeared in copyrighted material must be accompanied by written permission for their use from *the copyright owner and original author* along with complete reference information. Photographs of identifiable persons must be accompanied by signed releases. If not, all recognizable features must be masked.

Requirements for certain types of manuscripts

Case reports and brief clinical and basic science communications. Limit of 700 words, 2 references. Include *standard abstract format*, of 50 words maximum, 3 to 5 key words/phrases for indexing purposes, and short title. If tables and/or figures are used, an equivalent number of words must be deducted from the total (see "Estimating Length of Manuscript").

Current Investigation. Same requirements as for regular article. The abstract *must* follow the *structured format*.

Clinical Opinion. Limit of 3000 words. Include *standard abstract format* of 50 to 150 words, 3 to 5 key words/phrases, and short title. Submit to Dr. Zuspan.

Current Development. Limit of 6000 words. Include *standard abstract format* of 50 to 150 words, 3 to 5 key words/phrases, and short title. Submit to Dr. Zuspan.

Letters to the Editors. *Letters to the Editors* must be submitted in duplicate, typed double-spaced, and the text of the manuscript must be limited to a maximum of 400 words (excluding references, name[s] and address[es] of the signer[s], and the phrase "To the Editors"). The submitted *Letter to the Editors* must be accompanied by a signed copyright statement. If there are two or more signers of the *Letter to the Editors,* one of the authors may sign the copyright statement but must add to the statement the following: "I sign for and accept responsibility for releasing this letter on behalf of any and all cosigners." These requirements apply to all types of *Letters to the Editors*. Letters should be sent to Dr. Zuspan.

Two types of letters will be considered for publication. (1) A *Letter to the Editors* commenting on an article that has appeared in the JOURNAL should be brief and directly related to the published article. The editorial staff reserves the right to shorten letters if necessary and to make minor editorial alterations without reference to the writer. Letters may be published together with a reply from the original author. If the original author does not respond, a notation indicating "Response declined" will be published. As space for letters is limited, only a selection of letters submitted may be published. (2) A brief case presentation or a short report of a pertinent observation in the form of a *Letter to the Editors* will be considered for publication.

Announcements. Announcements of major meetings and other significant activities must be received at least 8 weeks before the desired month of publication. All announcements carry a charge of $60 U.S., and the fee must accompany the request to publish. Information will be limited to title of meeting, date, place, and an address to obtain further information. Send announcements and payment, payable to this JOURNAL, to Kay G. Goehler, Senior Manuscript Editor, Journal Editing, Mosby–Year Book, Inc., 11830 Westline Industrial Drive, St. Louis, MO 63146-3318.

Books. Books received will be listed in the JOURNAL. They should be sent to Dr. Zuspan. No books will be returned.

Reprints

The corresponding author will receive a price schedule and order form at the time of publication. Reprints in quantities must be ordered from the Publisher with the author's consent.

Business communications

Communications of a business nature and all advertising communications should be addressed to: Journal Publisher, Mosby–Year Book, Inc., 11830 Westline Industrial Drive, St. Louis, MO 63146-3318, or call Journal Advertising Production Manager (1-800-325-4177, ext. 4306, or 314-453-4306).

CHECKLIST AND COPYRIGHT STATEMENT

Both the checklist and the copyright statement forms **must be completed** and sent with each submitted manuscript. If **not** completed, these forms will be returned to the author for completion.

These items appear in each monthly issue of the JOURNAL. A photocopy may be used. An exposition of the requirements given in the checklist is in the Information for Authors, which is published in each issue of the JOURNAL.

CHECKLIST

General

—The original and two copies of the manuscript are submitted.
—The completed checklist is enclosed. The assignment of copyright signed by **all** authors accompanies the manuscript.
—Human experimentation has been approved by the local institution as stated in the *Material and Methods* section.
—Guidelines for the care and use of *nonhuman* animals or *other species* approved by the institution have been followed as indicated in the *Material and Methods* section. *The species is named in the title, abstract, key words, and* Material and Methods *section.*
—The covering letter with essential information is with the manuscript.
—All elements of the manuscript are typed in English double-spaced on bond paper with 1-inch margins at top, bottom, and sides.
—All pages are numbered in the following order: title page, condensation, structured or standard abstract, body of the text, acknowledgments only of persons who have made substantive contributions to the study, references, legends, and tables.
—Signed, written permission from both the copyright holder and the original author for the use of tables, figures, or quotations previously published and their complete references are enclosed with the manuscript.
—Signed, written permission for the use of quotations of personal communications and unpublished data has been obtained from the person(s) being quoted and is enclosed.

Authorship

—In the covering letter that accompanies the submitted manuscript I/we have confirmed that all authors fulfilled both conditions required for authorship.

Conflict of interest

—In the covering letter that accompanies the submitted manuscript the commercial association of the author or of any coauthors that might pose a conflict of interest is described.

Previous publications

—Enclosed with the submitted manuscript are two reprints each of articles the author and/or some of the coauthors have previously published, have submitted for possible publication, or have in manuscript form dealing with same patients, same animals, same laboratory experiment, or same data, in part or in full, as those reported in the submitted manuscript. Further explanation is provided in the covering letter that accompanies the submitted manuscript.
—Similarities, differences and explanation are provided in the covering letter that accompanies the submitted manuscript.

Reviewers

—Names and addresses of three suggested reviewers are enclosed.

Title page

—These elements are given in the following sequence, and are typed double-spaced.
—Title.
—Author(s) name(s) and highest academic degree(s) are shown.
—City(ies), state(s), and country other than United States in which the study was conducted are given.
—The name(s) of the institution(s) section(s), division(s), department(s) in which the study was performed is provided and the institutional affiliation(s) of the author(s) at the time of the study is indicated.
—Acknowledgment of financial support is cited.
—Name, address, business and home telephone numbers, and fax number of author to whom requests for reprints are to be sent are included.
—If reprints will not be available, this has been stated on the title page.
—If the corresponding author is different from the author to whom reprint requests are to be sent, his/her name, address, business and home telephone numbers, and fax number have been added.
—At the bottom of the page, a running head not exceeding 52 characters (including word spaces) has been typed.

Condensation

—On a separate sheet of paper, page 2 of the manuscript, a single sentence limited to 25 words delineating the essential point(s) is typed double-spaced.

Abstract and key words or short phrases

—The abstract (structured or standard format) is typed double-spaced with required margins on page 3 headed by the title and author(s) name(s). Beneath the abstract 3 to 5 key words or short phrases are typed.
—A *structured abstract,* with 150 words or less, is submitted as required for regular articles, society regular-type articles, and Current Investigation articles. The abstract contains the four required major headings: Objective(s), Study Design, Results, and Conclusion(s), each with a brief adequate presentation.
—A *standard abstract* is submitted as required for Clinical Opinion and Current Development articles with 50 to 150 words and for case reports and brief communications articles with a maximum of 50 words, be they independent or society articles.

References

—Are typed double-spaced.

—Are numbered consecutively in the order they are cited in the text.

—The format of the "Uniform Requirements for Manuscripts Submitted to Biomedical Journals" is used. Examples shown in Information for Authors have been followed.

—Personal communications and unpublished observations are not used as numbered references but are mentioned in the text with the written approval of the person being quoted. The signed approval is enclosed.

Figures

—Each is numbered with an Arabic numeral and cited in numeric sequence in the text.

—Three sets of unmounted glossy prints for *black-and-white* figures are submitted, properly numbered, labeled, and *top indicated* on the back of each print.

—Three sets of original computer-generated figures printed on heavy coated paper with either a glossy or dull finish, unmounted, each one on a page, and properly labeled on the back and *top indicated* are submitted. None are dot matrix or photographic prints.

—Original transparencies of *color photographs* appropriately numbered and identified and *top indicated* are submitted along with two sets of unmounted prints on glossy paper, numbered and identified on the back.

Figure legends

—Are provided for each figure.

—Are numbered and typed together in numeric order on one sheet of paper (more if necessary). The page is numbered in sequence after the References page(s).

Tables

—Each table headed by a title and numbered in Roman numerals is typed double-spaced on a separate page.

—Tables are cited in numeric sequence in the text.

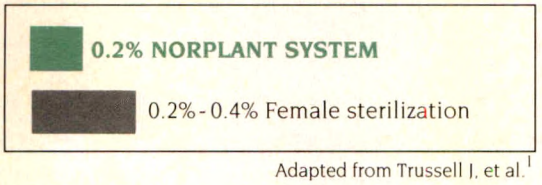
NORPLANT® SYSTEM

levonorgestrel implants



Six reasons why you can feel comfortable recommending it to your patients

Effectiveness comparable to tubal ligation

Although no contraceptive is 100% effective, the NORPLANT SYSTEM is one of the most effective forms of birth control ever developed. The average annual gross pregnancy rate over a five-year period is less than 1%.

Lowest expected and typical failure rates with NORPLANT SYSTEM vs. sterilization during first-year use[1]

Adapted from Trussell J, et al.[1]

Long-term convenience... estrogen-free

NORPLANT SYSTEM, a progestin-only contraceptive, is an excellent option for women desiring a long-term method. Its effectiveness lasts for five years and is not dependent on compliance.

Reversible, with prompt return to previous level of fertility

NORPLANT SYSTEM is reversible at any time; the contraceptive effect ceases when the capsules are removed. In one study, 40% of women wanting to conceive did so within 3 months of removal, 63% by 6 months, 76% by 12 months, and 90% by 24 months.[2]

High patient acceptance despite menstrual pattern changes

NORPLANT SYSTEM causes menstrual irregularities (the most common complaint),* which occur in many women during first-year use and diminish over time. Only 9.1% of patients discontinued during first-year use due to these changes.[3†]

Women who are thoroughly informed of potential menstrual changes and side effects are more tolerant of them when they occur.[4]

Well-received, well-liked by American women

One study of 140 users revealed that 94% were satisfied with NORPLANT SYSTEM, 91% recommended it to their friends, and 74% wanted to use it again.[5]

A 10- to 15-minute office procedure

A local anesthetic and a small 2 mm incision...little or no discomfort during insertion...proper placement should not leave a noticeable scar...in most cases sutures are not needed.

*Serious as well as minor side effects may occur (see prescribing information).

†Based on multicenter trials of 2,470 women.

Please see brief summary of prescribing information on adjacent page.

NORPLANT® SYSTEM
levonorgestrel implants

Lasts 5 years...yet is reversible

NORPLANT® SYSTEM

levonorgestrel implants

Lasts five years…yet is reversible

BRIEF SUMMARY OF PRESCRIBING INFORMATION. CONSULT THE PACKAGE LITERATURE FOR FULL PRESCRIBING INFORMATION.

Indications and Usage

The NORPLANT SYSTEM is indicated for the prevention of pregnancy and is a long-term (up to 5 years) reversible contraceptive system. The capsules should be removed by the end of the 5th year. New capsules may be inserted at that time if continuing contraceptive protection is desired.

Contraindications

1. Active thrombophlebitis or thromboembolic disorders. 2. Undiagnosed abnormal genital bleeding. 3. Known or suspected pregnancy. 4. Acute liver disease; benign or malignant liver tumors. 5. Known or suspected carcinoma of the breast.

Warnings

A. WARNINGS BASED ON EXPERIENCE WITH THE NORPLANT SYSTEM

1. *Bleeding Irregularities* — Most women can expect some variation in menstrual bleeding patterns. Irregular menstrual bleeding, intermenstrual spotting, prolonged episodes of bleeding and spotting, and amenorrhea may occur, and could mask symptoms of cervical or endometrial cancer. Overall, these irregularities diminish with continued use. Because amenorrhea may occur, missed menstrual periods cannot serve as the only identifier of early pregnancy. Perform pregnancy tests whenever pregnancy is suspected. If pregnancy occurs, the capsules must be removed. Hemoglobin concentrations found in clinical trials generally indicated that reduced menstrual blood loss is associated with NORPLANT SYSTEM use. Blood loss resulting in hemoglobin values consistent with anemia occurred rarely.

2. *Delayed Follicular Atresia* — Atresia of the follicle is sometimes delayed, resulting in enlarged follicles that are clinically indistinguishable from ovarian cysts. In the majority of women, enlarged follicles disappear spontaneously. Rarely, they twist or rupture and surgical intervention may be required.

3. *Ectopic Pregnancies* — Ectopic pregnancies have occurred among NORPLANT SYSTEM users, although clinical studies have shown no increase in the rate of ectopic pregnancies per year among NORPLANT SYSTEM users as compared with users of no method or of IUDs. The incidence among NORPLANT SYSTEM users (1.3 per 1000 woman-years) was significantly below the rate estimated for noncontraceptive users in the U.S. (2.7 to 3.0 per 1000 woman-years). Ectopic pregnancy risk may increase with duration of NORPLANT SYSTEM use and increased weight of the user. Rule out ectopic pregnancy in any patient presenting with lower-abdominal pain.

4. *Breast-feeding* — Steroids are not the contraceptives of first choice for lactating women. Levonorgestrel has been identified in breast milk. Limited data suggests no significant effects on infant growth or health when mothers used the NORPLANT SYSTEM beginning 6 weeks after parturition.

5. *Foreign-body Carcinogenesis* — Rarely, cancers occur at foreign-body intrusion sites or old scars. None has been reported in NORPLANT SYSTEM clinical trials and risk to users is judged to be minimal.

6. *Thromboembolic Disorders* — Remove capsules if active thrombophlebitis or thromboembolic disease develops. With prolonged immobilization removal should be considered.

B. WARNINGS BASED ON EXPERIENCE WITH COMBINATION (PROGESTIN PLUS ESTROGEN) ORAL CONTRACEPTIVES (OCs)

Note: Many of the side effects or risks listed below are thought to be estrogen-related; the association of the NORPLANT SYSTEM progestin-only method to these risks is unknown.

1. *Cigarette Smoking* — Cigarette smoking increases the risk of serious cardiovascular side effects from combined OC use. Risk increases with age and heavy smoking (≥15 cigarettes/day) and is quite marked in women over 35 years old.

2. *Elevated Blood Pressure* — Increase in blood pressure has been reported in combination OC users; prevalence increases with long exposure.

3. *Thromboembolic Disorders and Other Vascular Problems* — An increased risk of thromboembolic and thrombotic disease is associated with combination OC use. Estimate of relative risk is 4- to 11-fold higher for users vs. nonusers.

Cerebrovascular Disorders: Combination OCs increase the relative and attributable risk of cerebrovascular events (thrombotic and hemorrhagic strokes). Generally, risk is greatest among hypertensive women > 35 years of age who smoke.

Myocardial Infarction (MI): An increased risk of MI has been attributed to combined OC use. This is thought to be primarily thrombotic in origin and related to the estrogen component. Increased risk occurs primarily in smokers or women with other underlying risk factors for coronary-artery disease. Relative risk of heart attack for combined OC users is estimated as 2 to 6 times that for nonusers. Absolute risk is very low for women under 30 years old.

Studies indicate a significant trend toward higher MI and stroke rates with increased progestin doses in combination OCs. However, recent data indicated no increased MI risk with past use of levonorgestrel-containing OCs.

4. *Carcinoma* — Recent evidence in the literature suggests no association between OC use and increased risk of breast cancer in the overall population of users. The Cancer and Steroid Hormone (CASH) study also showed no latent effect on breast cancer risk for at least a decade following long-term use. Some of these same studies have shown an increased relative risk of breast cancer in certain subgroups; no consistent pattern has been identified. Some studies suggest an association between combination OCs and an increase in the risk of cervical intra-epithelial neoplasia in some populations of women. The extent to which such findings may be due to differences in sexual behavior and other factors remains controversial. A cause-and-effect relationship between combined OC use and breast or cervical cancer has not been established. Combination OCs may decrease ovarian and endometrial cancer risk. Irregular bleeding patterns associated with NORPLANT SYSTEM use could mask cervical or endometrial cancer symptoms.

5. *Hepatic Tumors* — Hepatic adenomas are associated with combination OC use; estimated incidence is 3 events per 100,000 users per year. Risk increases after 4 or more years of use. Hepatic adenomas are benign but may rupture and cause death through intra-abdominal hemorrhage.

6. *Ocular Lesions* — Retinal thrombosis is associated with OC use and is believed to be related to the estrogen component. However, NORPLANT SYSTEM capsules should be removed if there is unexplained partial or complete vision loss; onset of proptosis or diplopia; papilledema; or retinal vascular lesions. Undertake appropriate diagnostic and therapeutic measures immediately.

7. *Use Before or During Early Pregnancy* — Extensive epidemiological studies reveal no increased risk of birth defects when OCs are used prior to pregnancy. Studies also do not suggest a teratogenic effect when taken inadvertently during early pregnancy. No evidence suggests that risk with NORPLANT SYSTEM use is different.

8. *Gallbladder Disease* — Early studies reported an increased lifetime relative risk of gallbladder surgery in OC or estrogen users. More recent studies, however, indicate that the relative risk of gallbladder disease with OC use may be minimal; this may be related to use of OCs with less estrogen and progestin content.

Precautions

GENERAL

1. *Physical Examination and Follow-up* — A complete medical history and physical examination should be taken prior to implantation or reimplantation of NORPLANT SYSTEM capsules and at least annually during its use. Exams should include special reference to the implant site, blood pressure, breasts, abdomen and pelvic organs, including cervical cytology and relevant laboratory tests. Rule out malignancy in cases of undiagnosed, persistent or recurrent abnormal vaginal bleeding. Women with a strong family history of breast cancer or who have breast nodules should be monitored with particular care.

2. *Carbohydrate Metabolism* — Altered glucose tolerance is found in some combination and progestin-only OC users. Effects of NORPLANT SYSTEM on carbohydrate metabolism appear minimal. Observe diabetic and prediabetic patients carefully while using the NORPLANT SYSTEM. Follow women being treated for hyperlipidemias closely if using the NORPLANT SYSTEM. Some progestins may elevate LDL and may render control of hyperlipidemias more difficult. (See **Warnings**.)

3. *Liver Function* — Consider removing capsules if jaundice develops. Steroid hormones may be poorly metabolized in patients with impaired liver function.

4. *Fluid Retention* — Steroid contraceptives may cause some degree of fluid retention. Prescribe with caution, and careful monitoring, in patients with conditions possibly aggravated by fluid retention.

5. *Emotional Disorders* — Consider removing capsules if significant depression occurs since the symptom may be drug-related. Observe carefully those with history of depression and consider removal if depression recurs to a serious degree.

6. *Contact Lenses* — Contact-lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist.

7. *Insertion and Removal* — Insertion is advised during the first 7 days of the cycle or immediately following abortion to insure that the woman is not pregnant and to assure contraceptive effectiveness during first cycle of use. Capsules may be inserted at any time during the cycle provided pregnancy has been excluded and a nonhormonal contraceptive method is used for the remainder of the cycle. Insertion is not recommended before 6 weeks postpartum in breast-feeding women. Follow insertion and removal instructions closely. Healthcare professionals are strongly advised to be instructed in the procedures before they attempt them. Proper insertion just under the skin facilitates removals; proper insertion and removal should result in minimal scarring. If all capsules cannot be removed at first attempt, attempt removal later when the site has healed. Bruising may occur at implant site during insertion or removal. Hyperpigmentation may occur over implant site but is usually reversible following removal. **See Full Prescribing Information for Detailed Insertion/Removal Instructions.**

8. *Infections* — Implant site infection has been uncommon (0.7%); aseptic technique and proper insertion/removal reduces possibility of infection. Institute treatment if infection occurs; remove capsules if infection persists.

9. *Expulsion* — Expulsion of capsules was uncommon; frequency increased when capsule placement was extremely shallow, was too close to incision, or when infection was present. Replace expelled capsule with new sterile capsule. Treat and cure any infection before replacement. Contraceptive efficacy may be inadequate with fewer than 6 capsules.

10. *Provisions for Removal* — Advise women that capsules may be removed at any time for any reason. Personnel instructed in removal technique should perform removal on request or at the end of 5 years of usage. Upon removal, dispose of capsules in accordance with Centers for Disease Control Guidelines for biohazardous waste.

DRUG INTERACTIONS: Reduced efficacy (pregnancy) in NORPLANT SYSTEM users has been reported when phenytoin or carbamazepine were used concomitantly. Warn NORPLANT SYSTEM users of possible decreased efficacy with use of related drugs.

DRUG/LABORATORY TEST INTERACTIONS: 1. Sex-hormone-binding globulin concentrations are decreased. 2. Thyroxine concentrations may be slightly decreased and triiodothyronine uptake increased.

CARCINOGENESIS: See **Warnings** section and Full Prescribing Information.

PREGNANCY: Pregnancy Category X. See **Warnings** section and Full Prescribing Information.

NURSING MOTHERS: See **Warnings** section and Full Prescribing Information.

INFORMATION FOR THE PATIENT: See Patient Labeling. Provide copy of patient labeling to the patient. Advise patients that Prescribing Information is available upon request. Inform prospective users of risks and benefits associated with NORPLANT SYSTEM use, with other forms of contraception, with no contraception, and about insertion/removal procedures. Informed consent from all patients may be desired in light of techniques involved with insertion and removal.

Adverse Reactions

The following have been associated with the NORPLANT SYSTEM during first year of use: many bleeding days or prolonged bleeding (27.6%); spotting (17.1%); amenorrhea (9.4%); irregular (onsets of) bleeding (7.6%); frequent bleeding onsets (7.0%); scanty bleeding (5.2%); pain or itching near implant site - usually transient - (3.7%); infection at implant site (0.7%); removal difficulties affecting subjects - based on 849 removals - (6.2%).

Controlled clinical studies suggest that the following, occurring during the first year, are probably associated with NORPLANT SYSTEM use: headache; nervousness; nausea; dizziness; adnexal enlargement; dermatitis; acne; change of appetite; mastalgia; weight gain; hirsutism, hypertrichosis and scalp-hair loss. The following were reported with a frequency of 5% or greater during the first year and possibly may be related to NORPLANT SYSTEM use: breast discharge; cervicitis; musculoskeletal pain; abdominal discomfort; leukorrhea; vaginitis.

Overdosage

Overdosage may cause fluid retention with its associated effects and uterine bleeding irregularities.

Dosage and Administration

The NORPLANT SYSTEM consists of six Silastic® capsules, each containing 36 mg of the progestin levonorgestrel. The total administered (implanted) dose is 216 mg. Implantation of all six capsules should be performed during the first 7 days of the onset of menses by a healthcare professional instructed in the NORPLANT SYSTEM insertion technique. Insertion is subdermal in the midportion of the upper arm about 8 to 10 cm above the elbow crease. Distribution should be in a fanlike pattern, about 15 degrees apart, for a total of 75 degrees. Proper insertion will facilitate later removal. **(See Full Prescribing Information for Detailed Insertion/Removal Instructions.)**

Low-dosage micronized 17β-estradiol prevents bone loss in postmenopausal women

Bruce Ettinger, MD,[a] Harry K. Genant, MD,[b] Peter Steiger, PhD,[c] and Phillip Madvig, MD[d]

Oakland and San Francisco, California, and Waltham, Massachusetts

With the use of a double-blind, randomized, dose-ranging design, we tested during an 18-month period the degree of protection against postmenopausal bone loss afforded by micronized 17β-estradiol in dosages of 0.5, 1.0, and 2.0 mg. All subjects received supplementation to ensure a minimum of 1500 mg calcium daily. Fifty-one subjects completed at least 1 year of follow-up bone density measurements by quantitative computed tomography and by single- and dual-photon absorptiometry. In the placebo group spinal trabecular bone density decreased 4.9% annually ($p < 0.001$), whereas in those taking micronized 17β-estradiol bone density tended to increase (annual increases of 0.3% in the 0.5 mg micronized 17β-estradiol group, 1.8% in the 1.0 mg micronized 17β-estradiol group, and 2.5% in the 2.0 mg micronized 17β-estradiol group). After completing the double-blind phase, 41 subjects completed an additional 18 months of follow-up while taking 1.0 mg micronized 17β-estradiol. During this time one third of the subjects were randomly assigned to discontinue calcium supplements. Among those who previously received placebo, trabecular bone density increased 4.3% annually, whereas among those who had used micronized 17β-estradiol, trabecular bone density response was inversely related to the dosage previously used. Additionally and independently, the level of calcium intake showed a statistically significant correlation with the change in spinal trabecular bone density ($r = 0.37$, $p = 0.02$). We conclude that micronized 17β-estradiol has a continuous skeletal dose-response effect in the range of 0.5 to 2.0 mg and that calcium intake positively modifies the skeletal response to 1.0 mg micronized 17β-estradiol. (AM J OBSTET GYNECOL 1992;166:479-88.)

Key words: Absorptiometry, photon; bone density; calcium, dietary; estradiol; osteoporosis, postmenopausal

Ample evidence exists that estrogen deficiency causes bone loss in women. Estrogen replacement therapy can prevent or retard these losses, and long-term use reduces by 50% the risk of osteoporotic fractures.[1,2] Skeletal protection has been shown for various estrogen dosages: Minimum dosages of some estrogens have been determined from an uncontrolled observational study[3] and from double-blind, randomized, controlled clinical trials.[4-7] In an observational study[8] we found that most women could be protected against bone loss by taking half the customary dosage of conjugated estrogen plus a 1500 mg calcium intake. Several criticisms were leveled at that study: It did not use randomization or placebo controls, a low level of endogenous estrogen production could have persisted in the recently menopausal subjects, and two thirds of the women were also given a progestogen that could have enhanced estrogen's skeletal protection.

To assess the minimum effective dosage of micronized 17β-estradiol and to investigate the possible synergism between low-dosage estrogen and calcium, we designed a two-phase clinical trial, each phase lasting 18 months. The first was a double-blind, placebo-con-

6/1/32024

trolled, dose-ranging study. Because previously published studies of micronized 17β-estradiol showed that 2.0 mg produced an increase in bone mass but 1.0 mg did not fully prevent bone loss,[7] we chose a dosage range of 0.5 to 2.0 mg. These dosages appear to be biologically equivalent to 0.3 to 1.25 mg of conjugated estrogens.[9] Calcium supplementation, sufficient to raise the daily intake to 1500 mg, was given to all participants, but no progestogen was used. Surgically castrated women and spontaneously menopausal women were included. A second phase was designed to evaluate the possible synergism between calcium and low-dosage micronized 17β-estradiol. All subjects completing the first phase were given 1.0 mg micronized 17β-estradiol, and one third were randomly assigned to discontinue calcium supplements.

Material and methods

Subjects. Postmenopausal, predominantly white women aged 40 to 58 years were solicited by advertisement and by physician referral from among San Francisco Kaiser Permanente Medical Center members. The study protocol was approved by the Institutional Review Boards of the Kaiser Permanente Medical Care Program, Northern California Region, and the University of California, San Francisco, Medical Center. Menopause was confirmed by surgical report of bilateral oophorectomy or by absence of menses for ≥6 months. Estrogen deficiency was confirmed biochemically by the finding of a serum follicle-stimulating hormone level >40 U/L. At the start of the study, subjects were required to be within 5 years of menopause; they were stratified by years since menopause (<2.5 and ≥2.5 years). All women were ambulatory and healthy. Criteria for exclusion included presence of diseases or conditions known to affect skeletal health, including thyroid disorders, parathyroid disorders, any other disorders of calcium homeostasis, and use of anticonvulsants or glucocorticoids. Specifically excluded were women with evidence of renal, hepatic, cardiac, or malignant diseases. Body weight was required to be within 20% of ideal for height, as determined by Metropolitan Life Insurance Company tables.

Treatment

Phase 1. After informed consent was obtained, subjects were randomly assigned to placebo or identical-appearing active treatment with either 0.5, 1.0, or 2.0 mg of micronized 17β-estradiol (Estrace, Mead Johnson Laboratories, Div. of Bristol-Myers Co., Evansville, Ind.). Study pills were administered in a cyclic regimen on 23 of 28 days for 18 months. Pills returned unused at each 3-month visit were counted, and a new supply of pills was given. Calcium carbonate supplements, in the form of oyster shell calcium (Os-Cal, Marion Laboratories, Kansas City, Mo.), were given to raise the daily calcium intake above 1500 mg. In most cases 750 or 1000 mg of elemental calcium was required, but 29% of subjects required only 500 mg. The supplement was administered with meals, usually in two divided dosages.

Phase 2. On completing phase 1, subjects were not informed of their previous treatment assignment. They were counseled by an independent endocrinologist who was made aware of their previous treatment and bone density tests. This physician recommended participation in phase 2 unless previous use of 1.0 mg micronized 17β-estradiol had not protected that person against bone loss. After informed consent was obtained, subjects were enrolled in an open study in which all received 1.0 mg micronized 17β-estradiol for 25 days per month. Because we wanted to avoid subjecting these women to further risk of endometrial stimulation from prolonged exposure to unopposed estrogen, women with an intact uterus were also given medroxyprogesterone acetate, 10 mg daily, from day 13 to day 25 of each month. All subjects were advised to continue their usual diet, but, on the basis of a random number selection, one third of the subjects were instructed to discontinue calcium supplementation.

Bone mineral measurements. The primary efficacy assessment was spinal trabecular bone mass measured by quantitative computed tomography at the University of California Radiology Department. With a scanner (GE 9800, General Electric, Milwaukee), at 80 kV(p), this method obtains slices 10 mm thick through the midplane of vertebral bodies T-12 through L-3 and compares the density of an elliptic region of interest within each vertebra with a simultaneously scanned phantom containing different solutions of potassium phosphate. Results are expressed as trabecular bone density, in milligram per cubic centimeter potassium phosphate equivalents. Short-term precision in vivo was 1.5%,[10] whereas long-term precision, in vitro, determined on a phantom simulating a human torso, was 1.6%.[11] An analysis of statistical power estimated that sample sizes of nine per group would have a 90% chance ($p = 0.05$) of detecting a 4% change in spinal trabecular bone density.

In addition, two other density measurements were obtained. Spinal dual-photon absorptiometry was done with a rectilinear scanner (model 2600, Norland Corp., Fort Atkinson, Wis.) with a spatial resolution of 3 mm and long-term precision of 2.5%.[12] Results are expressed as bone mineral density in grams per square centimeter. In vitro phantom scans helped correct for longitudinal drifts associated with changes in gadolinium source and analytic software.[12] Radial single-photon absorptiometry was done with a Norland 278 digital bone densitometer. The radius is almost entirely cortical bone at the junction of the proximal two thirds and the distal one-third site used for measurement. The

nondominant arm was measured three times; the arm was removed from the scanner and repositioned, and measurements were repeated three times; the subject was again removed, repositioned, and measured three more times. With this procedure, the average of nine scans per sitting yielded a long-term precision of 2.0%. Results are expressed as bone mineral density in grams per square centimeter.

Bone density measurements were done every 6 months during the first phase of the study. For each study participant the slope, intercept (at baseline), and annual percentage change (slope divided by intercept) were determined from all available measurements with the least-squares regression formula. To be considered evaluable for bone density outcome analysis, subjects were required to have at least 1 year of follow-up and three bone density studies. Bone density measurements were done once again after 18 months of phase 2, and the annual percentage change was calculated from the difference between the final measurements of phase 1 and those of phase 2.

Other measurements. A food frequency dietary history, based on consumption of 30 calcium-containing foods, was obtained at baseline and at each 3-month visit. A daily average was calculated from the monthly estimate after the addition of 100 mg of calcium per day from noncoded sources. Menopausal symptoms were recorded at each visit, and a total score was calculated from the severity of 11 menopausal symptoms, according to the weighting system developed by Kupperman et al.[13]; the maximum score on the Kupperman index is 51.

When possible, endometrial biopsies were done at the beginning and end of phase 1. Unexpected uterine bleeding was also an indication for biopsy. Tissue samples were analyzed by a pathologist who was unaware of treatment status.

Subjects continued in the trial unless they voluntarily withdrew, were removed from study because of an adverse event, or, after 12 months, had lost spinal trabecular bone density at an annual rate >8%.

Results

Phase 1. Baseline characteristics of 63 women enrolled in the study are displayed in Table I. Randomization and stratification by menopausal age succeeded in providing similar bone mineral densities among treatment groups. The 29 subjects who were 2.5 to 5.0 years postmenopausal were 2.7 years older than the 34 subjects <2.5 years beyond menopause. The later postmenopausal group had 10.2% lower spinal trabecular bone density (109.6 ± 32.8 vs 122.1 ± 21.3 mg/mm^3; $p < 0.05$), 9.1% lower spinal bone mineral density (0.900 ± 0.180 vs 0.990 ± 0.15 gm/cm^2; $p = 0.01$), and 4.3% lower radial bone mineral density (0.670 ± 0.080 vs 0.700 ± 0.050 gm/cm^2; not statistically significant).

Compliance was excellent. Only one subject used <75% of the required number of pills. Overall, 41 subjects (65%) completed 18 months of follow-up. Eight left the study before any follow-up was done. Four additional subjects, all assigned to the active drug group, discontinued study after the first 6-month follow-up measurements for personal reasons unrelated to treatment or bone density changes. In all these cases bone density at 6 months was higher than that at baseline.

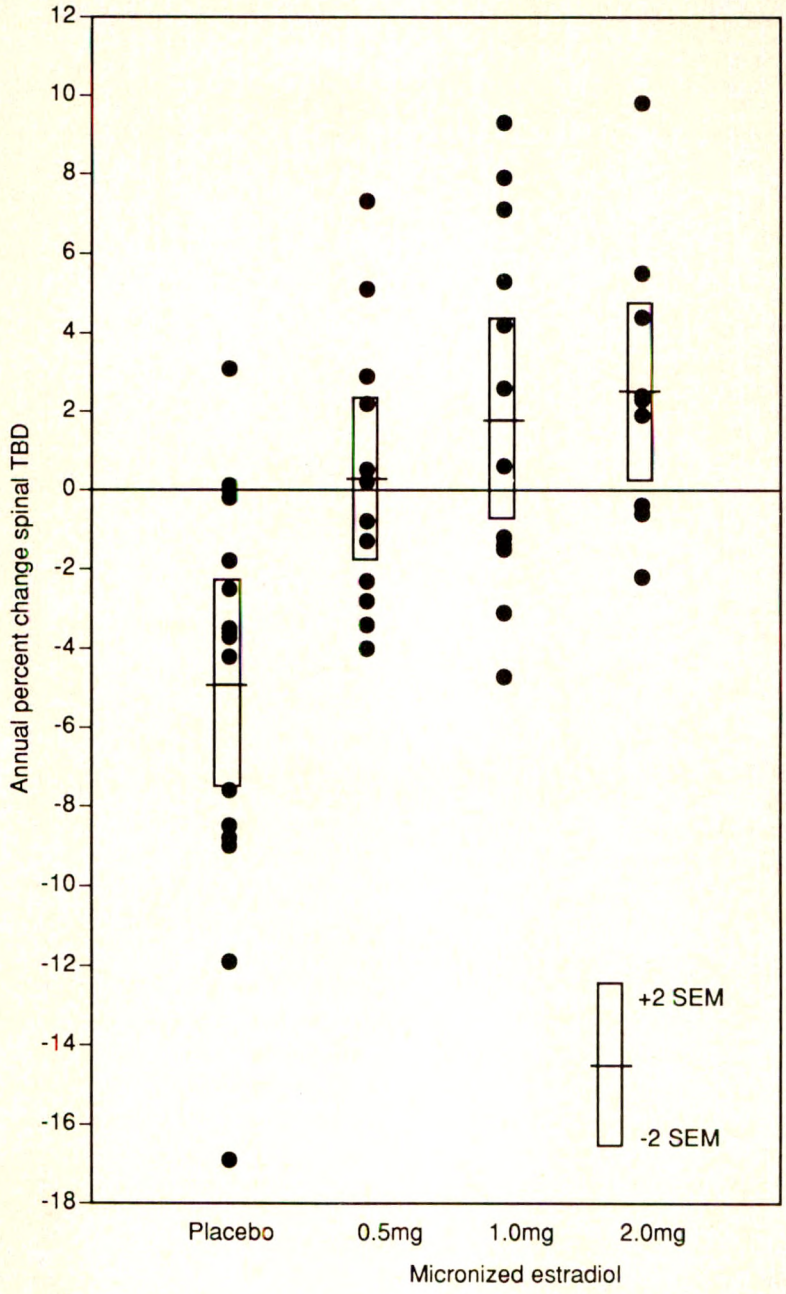

Fig. 1. Changes in mean (±2 SEM) annual percentage and each subject's spinal trabecular bone density *(TBD)* in 46 postmenopausal women given micronized estradiol (phase 1). All subjects received calcium supplements.

On the basis of the predetermined rule requiring a minimum of three bone measurements, data from these 12 subjects have been excluded from the outcome analysis. At 1 year of follow-up, five subjects taking placebo were removed from the trial because they had lost >8% of spinal trabecular bone density. Five additional subjects withdrew between the 12- and 18-month visits, two because of troublesome vaginal bleeding and three for reasons unrelated to treatment effects. Some adverse reaction, of at least moderate degree, was recorded for 37% of placebo users and for 33% of 0.5 mg, 37% of 1.0 mg, and 56% of 2.0 mg micronized 17β-estradiol users.

Placebo users had a statistically significant decrease in spinal trabecular bone density; the mean annual loss was 4.9% (95% confidence interval 2.4% to 7.5%). The changes in spinal trabecular bone density in all three groups treated with micronized 17β-estradiol were each statistically significantly different from the changes in the placebo group (analysis of variance, $p < 0.001$, vs

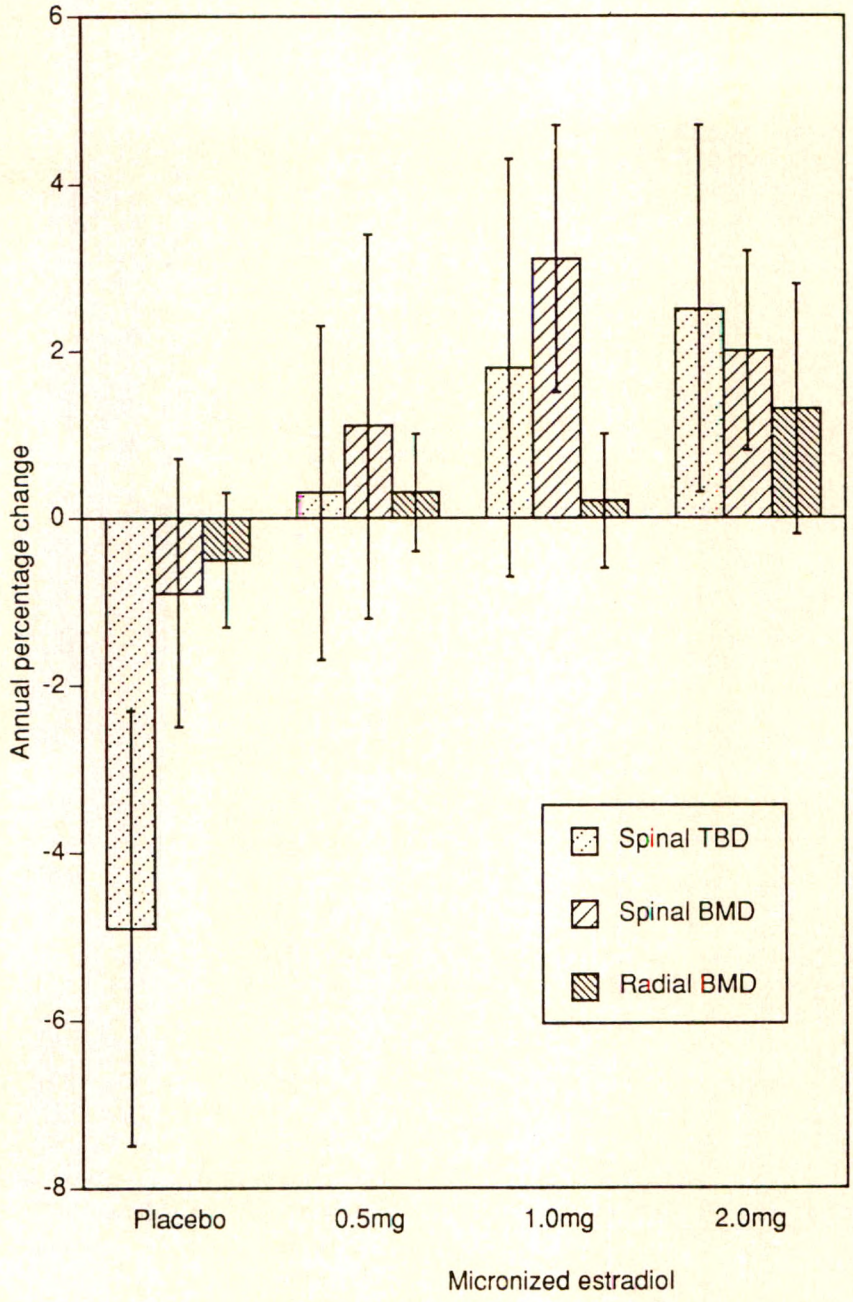

Fig. 2. Mean (±2 SEM) annual percentage change in spinal trabecular bone density *(TBD)*, spinal bone mineral density *(BMD)*, and radial bone mineral density in 46 postmenopausal women given micronized estradiol (phase 1). All subjects received calcium supplements.

placebo; Fig. 1). In the placebo group changes from baseline spinal bone mineral density (−0.9%) and radial bone mineral density (−0.5%) were not statistically significant. Changes in spinal and radial bone mineral density, although not statistically significant, tended to parallel the changes in spinal trabecular bone density (Fig. 2). The three bone measurements were statistically significantly correlated: spinal trabecular bone density versus spinal bone mineral density, $r = 0.58$, $p = 0.0001$; spinal trabecular bone density versus radial bone mineral density, $r = 0.28$, $p < 0.05$; spinal versus radial bone mineral density, $r = 0.28$, $p < 0.05$. Although we found no statistically significant differences in any bone parameter among the different micronized 17β-estradiol dosage groups, women assigned 1.0 and 2.0 mg dosages tended to have greater increases in spinal trabecular bone density than women assigned the 0.5 mg dosage (Fig. 2). When we compared women in all active treatment groups with women taking placebo, both spinal and radial bone mineral density

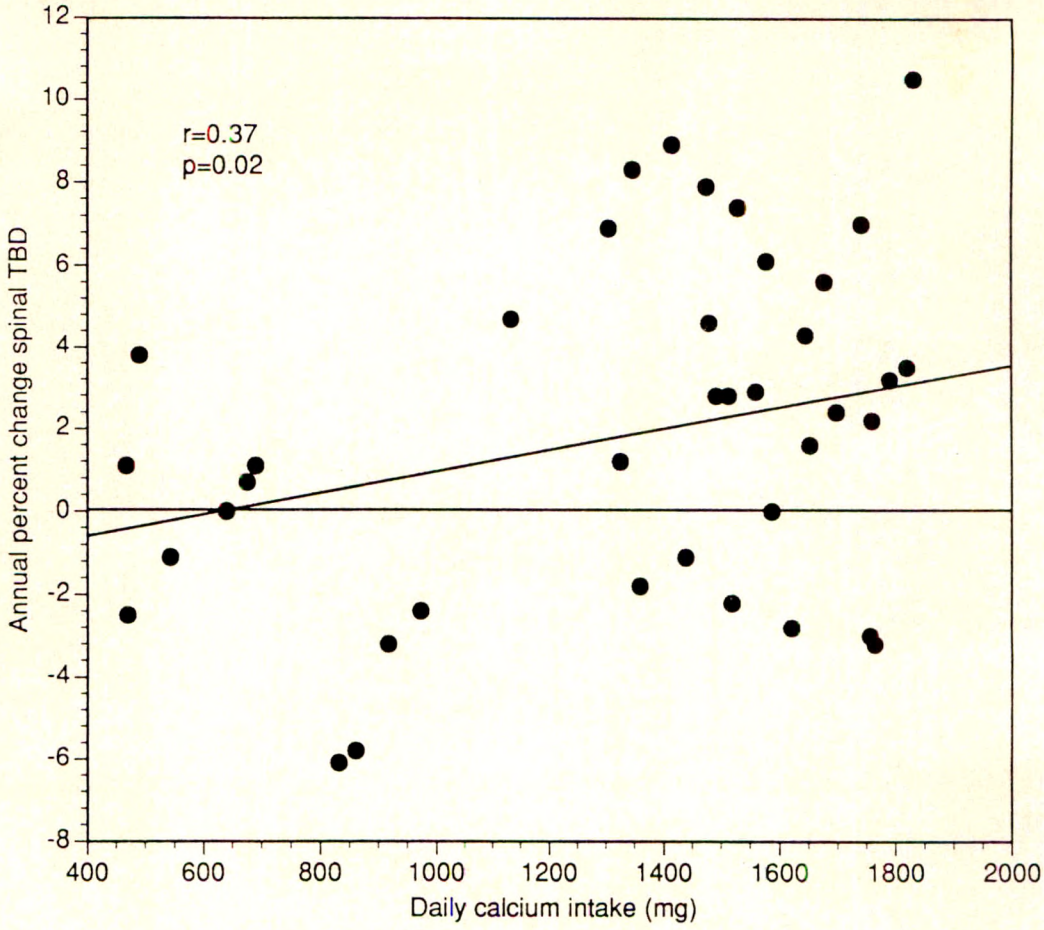

Fig. 3. Plot of annual percentage change in spinal trabecular bone density *(TBD)* in 41 postmenopausal women given 1.0 mg micronized estradiol by level of calcium intake (phase 2).

Table II. Endometrial biopsy results by treatment group

		Micronized estradiol		
	Placebo	*0.5 mg*	*1.0 mg*	*2.0 mg*
No. of subjects	14	8	11	9
Refused biopsy	6	1	4	0
Biopsy could not be performed	2	1	0	0
Atrophic endometrium	4	1	2	0
Proliferative endometrium	2	4	3	7
Hyperplasia of endometrium				
Cystic	0	0	0	1
Simple (with no atypia)	0	1	1	1
Complex (with atypia)	0	0	1	0

showed statistically significant differences. Smoking habit, type of menopause (spontaneous versus surgical), and recency of menopause did not statistically significantly influence changes in bone density.

Of the entire cohort, 17.5% had previous removal of ovaries and uterus. Of the women still at risk for gynecologic complications, no uterine bleeding was observed among 14 taking placebo or among 11 taking 0.5 mg micronized 17β-estradiol. Of 13 women taking 1.0 mg micronized 17β-estradiol, three experienced light withdrawal bleeding and one had unexpected troublesome bleeding. One of 14 women using 2.0 micronized 17β-estradiol experienced light withdrawal bleeding, and three others had unexpected troublesome bleeding. The results of endometrial sampling done at the end of phase 1 are displayed in Table II; hyperplasia was found in five of 23 (22%) biopsy specimens obtained from women taking micronized 17β-estradiol. Of these five, one had no bleeding, one had light, regular withdrawal bleeding, and the remaining three had irregular and heavy bleeding. The mean menopause symptom score during treatment was unchanged from baseline in women taking placebo (14.3 ± 7.1) but was statistically significantly reduced to 9.2 ± 10.1 ($p < 0.05$) in women taking 0.5 mg mi-

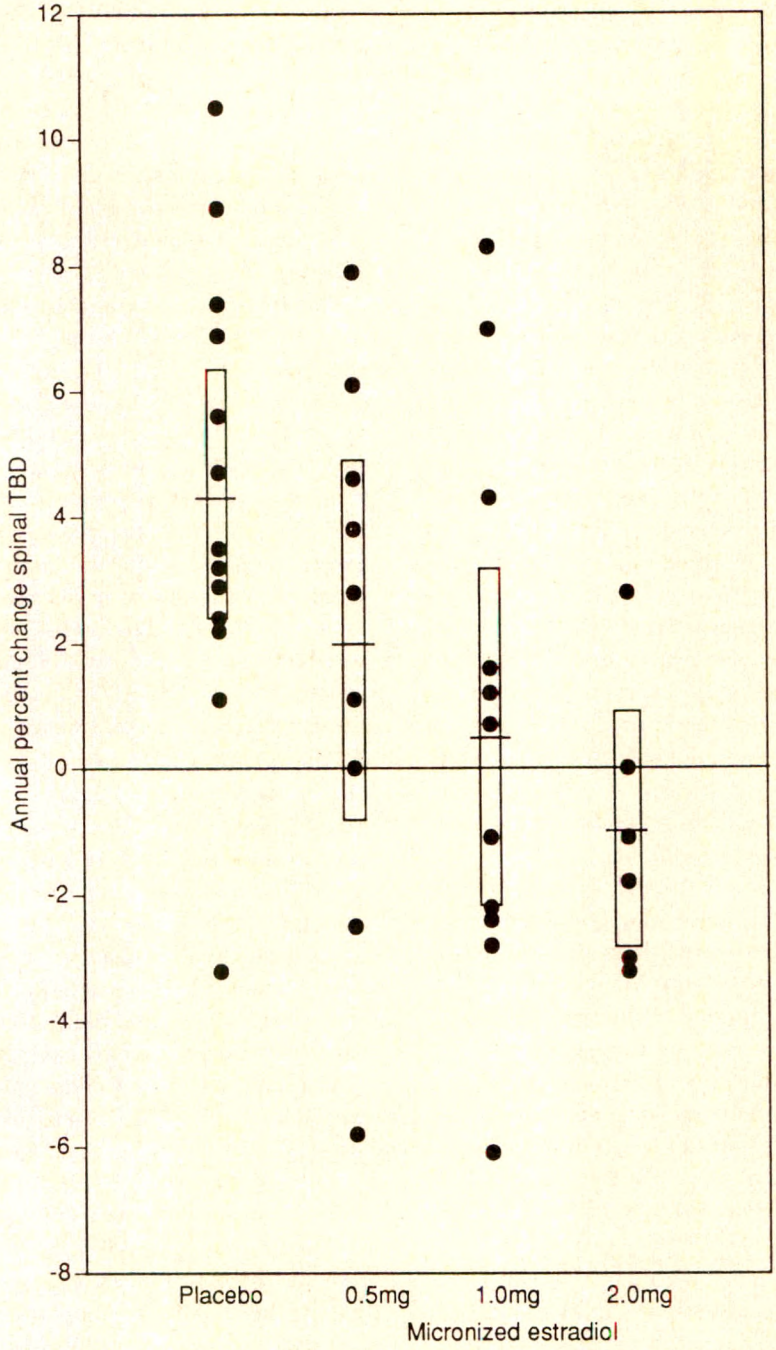

Fig. 4. Changes in mean (±2 SEM) annual percentage and each subject's spinal trabecular bone density *(TBD)* in 41 postmenopausal women given 1.0 mg micronized estradiol versus prior treatment (phase 2).

cronized 17β-estradiol, to 7.3 ± 13.0 ($p < 0.05$) in women taking 1.0 mg micronized 17β-estradiol, and to 7.5 ± 5.9 ($p < 0.01$) in women taking 2.0 mg micronized 17β-estradiol.

Phase 2. All subjects invited to continue agreed to comply with the drug and dietary instructions, and 41 completed the additional 18-month follow-up measurements. Women who were instructed to stop calcium supplements had an average daily dietary calcium intake similar to that which they received in phase 1 (830 ± 337 vs 804 ± 263 mg). Similarly, women assigned to continue calcium supplements did not statistically significantly alter their dietary calcium intake (826 ± 316 vs 787 ± 257 mg). Women who left this

phase of the trial (9.8%) did so for personal reasons, and none experienced serious adverse reactions. Of the 37 women with an intact uterus, seven (18.9%) had no withdrawal bleeding, two (5.4%) experienced fewer than three menses a year, and 28 (75.7%) had regular monthly withdrawal bleeding.

During the 18 months of extended treatment with 1.0 mg micronized 17β-estradiol, the annual change in spinal trabecular bone density was +2.0% (95% confidence interval 0.7% to 3.3%). We found a statistically significant positive correlation between total calcium intake and change in spinal trabecular bone density ($r = 0.37$, $p = 0.02$; Fig. 3). Previous treatment was a statistically significant independent predictor of the spinal trabecular bone density response to 1.0 mg micronized 17β-estradiol (Fig. 4). The greatest increases were observed among women previously assigned to placebo, with an average annual gain of 4.3% (95% confidence interval +2.3% to +6.3%). Women previously assigned to 0.5 mg micronized 17β-estradiol gained 2.0% (95% confidence interval −0.8% to +4.8%), women continuing on a regimen of 1.0 mg gained 0.5% (95% confidence interval −2.1% to +3.1%), and women whose dosage was reduced from 2.0 to 1.0 mg lost 1.0% (−2.8% to +0.8%). Changes in spinal trabecular bone density did not have a statistically significant correlation with smoking habit, type or recency of menopause, use of progestogen, previous rate of change in spinal trabecular bone density, or absolute level of spinal trabecular bone density. For the entire cohort, mean spinal bone mineral density increased 2.9% (95% confidence interval +1.7% to +4.1%), but we found no statistically significant correlations between changes in this measurement and previous dosage, calcium intake, or other clinical variables. We observed no statistically significant changes for radial bone mineral density (+0.3%), and this measurement did not correlate with any clinical variables.

Comment

Estrogen-deficient women lose mineral at all skeletal sites, but the greatest losses are in the trabecular bone of the vertebrae. Because of its high surface-to-volume ratio and its more rapid turnover, trabecular bone typically responds two to three times as much as cortical bone. Spinal trabecular bone density, with measurement of only the trabecular component of the vertebra, usually shows annual losses of 5% in women who have recently become estrogen deficient. Initiating estrogen therapy in women who have recently lost ovarian function typically increases spinal trabecular bone density about 5% in the first year and thereafter maintains it at a relatively constant level.[8] Both phases of the current study show this effect, which is probably related to a temporary imbalance between bone resorption and formation. Estrogen rapidly reduces bone resorption but allows the continuing repair and mineralization of previously active resorption sites (bone metabolic units). The skeletal response to estrogen (and other agents that reduce bone resorption) depends, in large part, on the degree of skeletal activation when treatment is begun. Gains in bone mass would be expected in women with a high turnover rate and a large skeletal remodeling space.

The first phase of our study lacked sufficient power to detect differences among women taking different dosages of micronized 17β-estradiol. We might have concluded, at the end of the first 18 months, that maximum skeletal protection could be achieved by 0.5 mg of micronized 17β-estradiol and that higher dosages did not augment this protection. However, in the second phase, when women previously taking 0.5 mg were given 1.0 mg, they appeared to show a further increase in spinal trabecular bone density. Conversely, women taking 2.0 mg appeared to lose bone when the dosage was reduced. On the basis of these observations, we conclude that there is a continuous dose-response effect in the range of dosages tested.

The first phase of our study was designed to assess the effects of estrogen apart from the usually coprescribed progestogen. In the second phase we were unable to show that medroxyprogesterone, 10 mg daily, given for 12 days per month, had any skeletal effects, although our power to detect this was limited. Although some have indicated that certain progestogens, particularly some 19-norsteroid derivatives, may prevent bone loss,[14] this effect has not been found for other 19-norsteroid progestogens or for medroxyprogesterone acetate, even in daily dosages of 20 mg.[15] Although the addition of a progestogen is not necessary for bone protection, it is unwise and impractical to give unopposed estrogens to women who still have an intact uterus. The incidence of troublesome bleeding and endometrial hyperplasia found when unopposed estrogen was used in our study is consistent with that of many other reports of unopposed estrogen use.

Most studies of women in the immediate postmenopausal years indicate that calcium has little or no effect.[8, 16, 17] Riis et al.[18] suggested that calcium, 2000 mg/day, could partially retard loss of total body calcium and cortical bone in the proximal radius, but it could not protect against spinal or distal radial mineral loss. Women who are several years beyond menopause[17, 19] or are elderly[20, 21] may derive some benefit from calcium. Certainly, very low calcium intakes should be avoided; they are associated with higher rates of bone loss[22] and increased risk of hip fracture.[23] In a study of 87 Danish women, Christensen et al.[7] tested micronized 17β-estradiol dosages of 1.0, 2.0, and 4.0 mg. These women, whose dietary calcium intake was probably

higher than that of women in the United States, were also supplemented with 500 mg of calcium. Bone mass as determined by radial single-photon absorptiometry decreased 2% in the placebo group, was unchanged in the low-dosage group, and was increased 1.5% and 2.0% in the medium- and high-dosage groups, respectively. In a nonrandomized, open study, Quigley et al.[1] compared 1.0 mg micronized 17β-estradiol or 0.625 mg conjugated estrogen with a regimen of no hormone treatment in 397 postmenopausal women aged 51 to 80 years. Subjects were asked to take 1000 mg of calcium daily if they were taking estrogen and 1500 mg if they declined estrogen treatment. Progestogens were not used. In each subject radial bone mineral density measurements were made initially and at the end of 3 years. Bone loss in both estrogen-treated groups was significantly less than in women using calcium alone, and the amount of protection provided by 0.625 mg conjugated estrogens was comparable with that provided by 1.0 mg micronized 17β-estradiol. Although the investigators in that study did not test lower dosages of either estrogen preparation and did not assess the axial skeleton, their conclusions are consistent with those of our study.

Protective effects of estrogen replacement therapy on bone mass have been shown in a randomized, prospective study with a mean 9-year follow-up.[24] Epidemiologic investigations have found greater bone mass among long-term estrogen users than among nonusers.[2, 25] Lindsay and Tohme[25] reported that spinal and femoral bone mass, measured by dual-photon absorptiometry, was about 20% greater in women who had used estrogen for 10 years. Spinal quantitative computed tomography measurements indicate even greater salutary effects; women using estrogen for an average of 17 years had about 50% higher levels than did nonusers.[2]

Can these same benefits be achieved with half as much estrogen? A synergism between estrogen and calcium is supported by several lines of evidence. An additive effect of endogenous serum estrone and calcium was observed in an epidemiologic study of radial bone density in 174 postmenopausal women.[26] In a prospective trial premenopausal women, mean age 37 years, were randomly assigned to consume more dairy products or to continue their usual diet.[27] In women assigned enhanced diets, with the average daily calcium intake increased by 610 mg, bone mineral density was maintained in a 3-year period, whereas bone was lost in control subjects. During the study some degree of ovarian insufficiency might have developed in these women. Just as the osteotrophic effects of suboptimal endogenous estradiol production may be enhanced by high calcium intake, suboptimal estrogen replacement therapy also may be enhanced. We previously reported that combining 0.3 mg conjugated estrogens with 1500 mg calcium was as effective as 0.6 mg of conjugated estrogens with no added calcium.[8] Extending these observations from 2 to 3 years yielded similar conclusions, although spinal trabecular bone density decreased between the second and third years, radial bone mineral density and metacarpal cortical thickness were well maintained,[28] and the 0.3 mg dosage with calcium appeared indistinguishable from the 0.6 mg dosage with no calcium. Our study lacked sufficient power to conclusively judge the comparative efficacies of these two estrogen regimens. Gallagher et al.[15] replicated these findings in a 2-year randomized study, which concluded that calcium alone, 1000 mg daily, was ineffective in preventing bone loss measured by quantitative computed tomography, dual-photon absorptiometry, single-photon absorptiometry, and total body calcium level, but 0.3 mg conjugated estrogens combined with 10 mg medroxyprogesterone acetate and a total intake of 1000 mg calcium was as effective as 0.625 mg conjugated estrogens alone. Genant et al.,[5] testing various dosages of piperazine estrone sulfate combined with 1000 mg of supplemental calcium, found 0.625 mg sufficient to prevent spinal trabecular mineral loss. Piperazine estrone sulfate, 0.625 mg, is considered by most investigators to be equivalent to 0.3 mg conjugated estrogens or to 1 mg of micronized 17β-estradiol because these dosages produce comparable clinical response and similar levels of plasma estradiol.[9] Our study indicates that, at least up to 3 years of treatment, a low dosage of micronized 17β-estradiol, 1.0 mg, is sufficient to prevent bone loss in women whose calcium intake is high (>1000 mg/day).

Proving the synergism between low-dosage estrogen and calcium requires considerable effort. First, the marked interpatient variability in treatment-induced estradiol levels must be overcome by titration of estrogen dosage to achieve a predetermined plasma level. Trial participants must be randomly assigned to low versus high calcium intakes. Institutional approval and recruitment of subjects to be submitted to low calcium intake would be difficult, given the present widespread belief in calcium's salutary effects. Large numbers of women would be needed, and follow-up for several years would be required to find any differences.

Most studies of estrogen's fracture prevention efficacy have examined the impact of estrogen use in the 1960s and 1970s, a time when the average estrogen dosage was equivalent to 0.9 mg of conjugated estrogens.[2] Most women now receive the equivalent of 0.625 mg, a dosage well documented to provide skeletal protection. Although lower dosages appear effective in preventing bone loss, their ability to prevent fractures has yet to be determined. Comparisons made in our study suggest that, in the long term, higher dosages

could provide greater protection against bone loss. Our current and previous[8] studies both found that although many women obtain relief of menopausal symptoms with low-dosage estrogen, some respond better to customary dosages. Furthermore, lower dosages of estrogen have little or no salutary effect on lipoprotein profile[29] and cannot be expected to have the same cardiovascular protective effect as full dosages.

Despite these theoretic and practical drawbacks, low-dosage estrogen may be a useful alternative to higher dosages. Women welcome the reduced amount and frequency of withdrawal bleeding. In spite of considerable evidence that customary dosages of estrogen are not associated with an increased risk of breast cancer,[30] this concern still prompts many women to request the lowest effective dosage. Although the possible synergism between calcium and low-dosage estrogen has not been rigorously proved, a coprescribed high-calcium intake may enhance bone preservation when lower-than-customary doses of estrogen are taken.

A controlled trial of self–nonstress test versus assisted nonstress test in the evaluation of fetal well-being

E. Albert Reece, MD, Zion Hagay, MD, Jill Garofalo, RNC, and John C. Hobbins, MD

New Haven, Connecticut, and Philadelphia, Pennsylvania

OBJECTIVE: New portable devices have become available for home monitoring of fetal heart rates; these devices have the potential to immediately transmit these tracings to a medical facility. The null hypothesis of this study is the inability of mothers to perform their own nonstress tests (self–nonstress tests) and that such tests are not comparable to those performed by professional medical personnel (assisted nonstress tests).

STUDY DESIGN: The feasibility of maternal self-testing was established in 50 high-risk patients followed by a controlled clinical trial conducted in 60 patients. The latter study represents the first controlled trial in which patients performed self–nonstress tests at their homes and transmitted the tracings via telecommunication to our perinatal unit. In all cases these patients came to our hospital within 60 minutes after the self–nonstress tests to have a perinatal nurse perform a second nonstress test. The pairs of self and assisted fetal heart rate tracings were independently reviewed by two investigators.

RESULTS: The self and assisted tracing pairs were judged satisfactory for interpretation in 100% and 90%, respectively; self and assisted were interpreted by each examiner to be nonreactive in 20% and 14%, respectively. However, both examiners were unable to distinguish between tracings generated by assisted nonstress and self–nonstress tests. Furthermore, cost analysis revealed an estimated twofold savings with self–nonstress testing compared with the assisted nonstress test.

CONCLUSION: Self–nonstress testing is a reliable and accurate method of antepartum fetal heart rate testing. This method of fetal assessment not only introduces a new approach to fetal surveillance with added convenience to patients, but may also significantly reduce medical cost without compromising the results of fetal testing. (Am J Obstet Gynecol 1992;166:489-92.)

Key words: Self–nonstress tests, assisted nonstress tests, antepartum

Antepartum fetal heart rate (FHR) testing is the cornerstone in the assessment of fetal well-being in high-risk pregnancies. As contemporary medicine attempts to maintain optimum care of patients with less inconvenience and to reduce the overall medical cost, various methods of home monitoring are being used. New equipment is now available that is easy to operate and can be used to transmit FHR tracings to medical facilities for review.[1, 2]

Investigators have previously reported successful transmissions of FHR tracings, by medical personnel, from regional hospitals to medical centers for consultation.[3-7] However, the feasibility of maternal self-testing with FHR transmission to a medical facility remained undetermined. In this study, we established the feasibility of self–nonstress testing (NST) in 50 patients and then performed the first controlled clinical trial in 60 patients in which self–NST was compared with assisted NST.

Material and methods

Feasibility study. High-risk patients undergoing antepartum FHR testing were trained, by a perinatal nurse, to perform self–NST and asked to conduct 30 minutes of FHR tracings. Patients were randomly recruited from the high-risk clinic, which comprises both private and university service patients. Therefore the patient population included both poorly educated and well-educated patients in fairly equal proportions. After an average instruction period of 15 minutes, patients were placed in a private room and asked to conduct self–NST. Tracings were independently and blindly reviewed by two investigators for technical quality and clinical interpretation.

Controlled trial. After the completion of the feasibility study, patients were given home monitors identical to those used in the hospital and were asked to conduct weekly self–NST from their homes. By telecommunication, the FHR tracings were transmitted to the Perinatal Unit (monitoring equipment from Advanced Medical Systems Inc., Hamden, Conn.). In all cases patients returned to our institution within 60 minutes to have a perinatal nurse perform a second non-

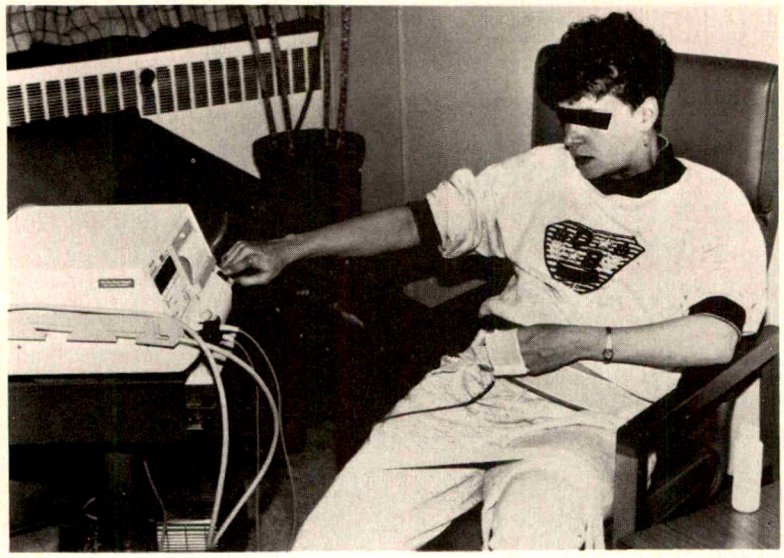

Fig. 1. Patient with twin gestation maintained at bed rest in her home conducted her own NST. She is seen placing belts around the abdomen and trying to find fetal heartbeat.

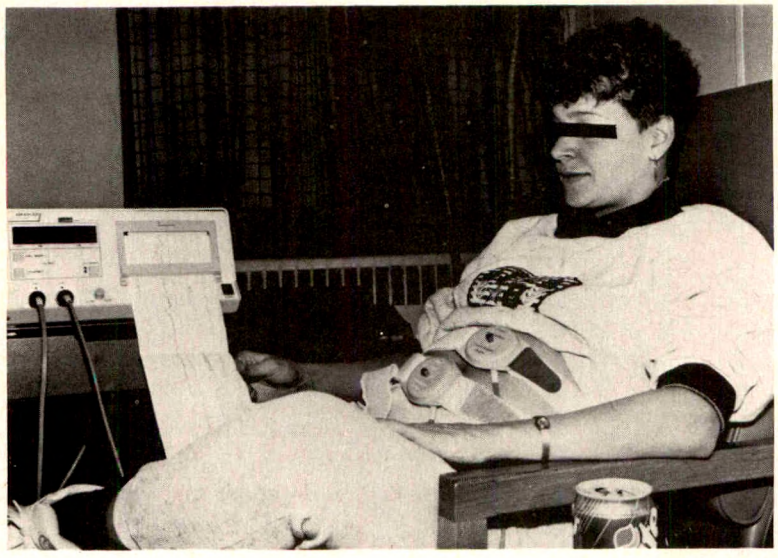

Fig. 2. Patient shown in Fig. 1 has identified FHR. Belts are already strapped around the abdomen, and she is observing dual tracing of both fetuses in progress. A copy of this tracing is being transmitted to the Perinatal Unit of Yale–New Haven Hospital for review.

stress test (assisted NST). The latter test was used for clinical purposes. The physicians and nurses involved in this study did not participate in the patient's high-risk clinical care. The 60 pairs of FHR tracings (both self- and assisted NST) were then independently assessed by two investigators who were blinded to the results of the study.

The fetal monitors used in the study were equipped with an internal memory that was capable of storing up to 80 minutes of heart rate and uterine activity data. The heart rate was digitized at a rate of four samples per second. The stored data were transferred by the telephone line with a 1200-band, half-duplex internal modem. One hour of data was transmitted in approximately 5 minutes. The receiver located in the perinatal unit automatically answered the call from the fetal monitor and recorded the incoming data on a strip chart in a manner similar to the original fetal monitor record (Figs. 1 and 2). The monitor is designed with a timer that allows the ultrasonography to be energized 90 minutes per day only, thus precluding the patient from using the machine all day.

Results

Feasibility study. All 50 patients in the feasibility phase of the study were able to initiate recordings of

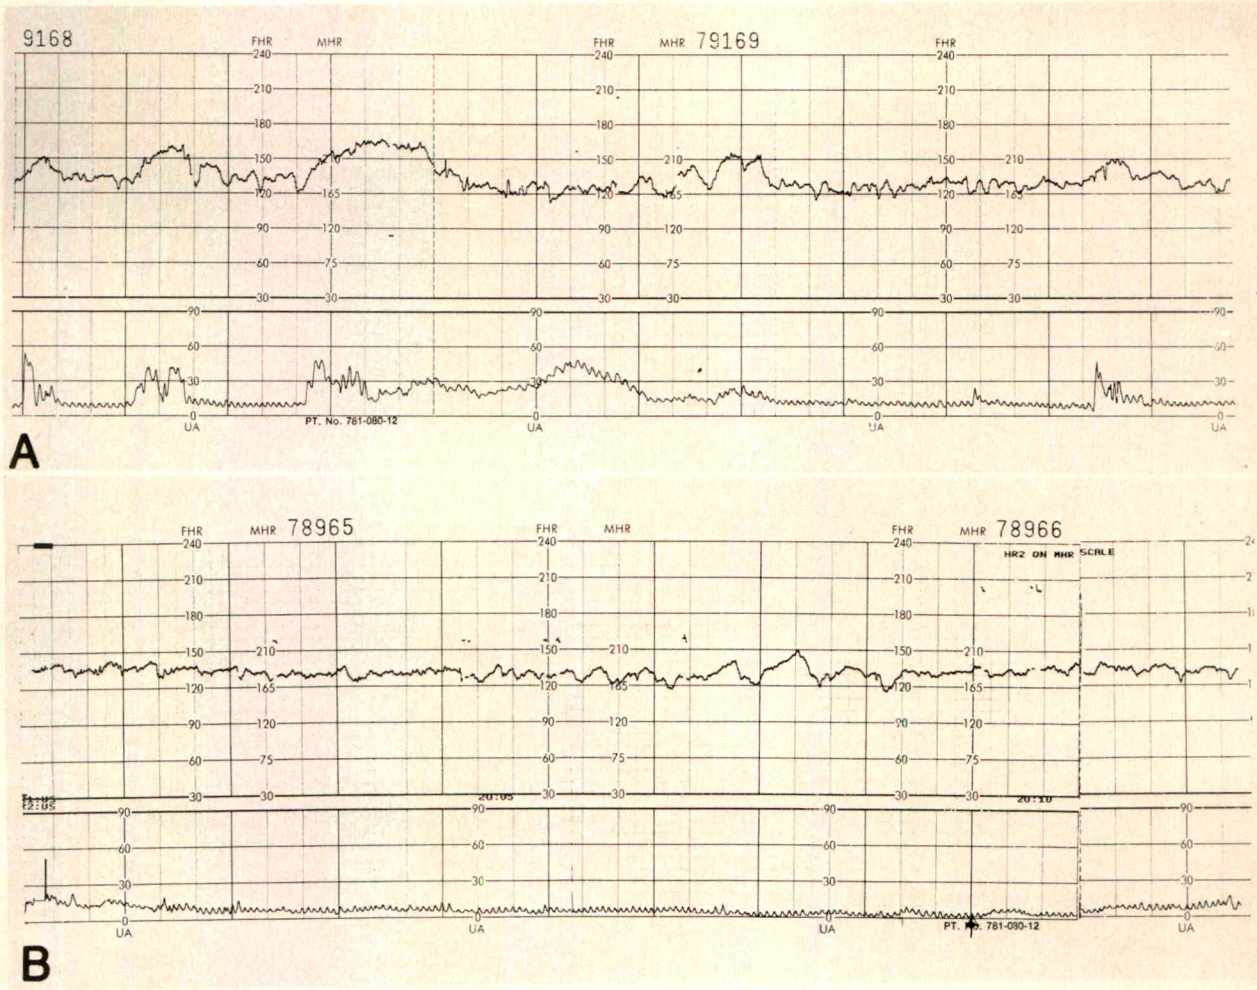

Fig. 3. A, Typical FHR tracing performed by patient (self-NST). **B,** Electronic FHR tracing performed by nursing staff (assisted NST).

the FHR by placing belts around their abdomen and identifying the FHR, then generating a tracing within 5 minutes (Fig. 1). The two investigators, who were blinded to the study, independently assessed the FHR tracings to be satisfactory and adequate for clinical interpretation.

Controlled trial. All patients in this phase of the study were able to successfully perform at-home, weekly self-NST and transmit tracings to our Perinatal Unit (Figs. 1 and 2). A total of 60 pairs of FHR tracings were generated, one performed by the patients at their homes and the other performed subsequently by a perinatal nurse in the hospital. Two investigators independently judged the FHR tracings to be satisfactory for interpretation in 100% and 96%, respectively. Additionally, these tracings were interpreted by each examiner to be nonreactive in 20% and 14%, respectively. However, both examiners were unable to distinguish between tracings generated by assisted NST and self-NST (Fig. 3).

Cost analysis reveals that self-NST would be cost saving by about twofold (Table I).

Comment

In the last decade the widespread use of electronic FHR monitoring in many delivery suites of regional hospitals necessitates the development of systems that may allow direct real-time telephone transmission of FHR signal to receiving units, principally for consultation.

Such systems have improved the quality of perinatal care in regional hospitals.[4, 5] Technologic advances in the last few years have lead to the development of new portable instrumentation that permits home tocodynamometry. This method of home monitoring of uterine activity is currently used in some medical centers as part of preterm delivery prevention programs. Recently, a new technique of transmitting FHR tracings from patients located extramurally to medical facilities has been developed.[2-8] In 1979, Boehm and Haire[7]

Table I. Cost analysis of miniaturized fetal data transmission unit versus regular fetal monitor

At-home program	
Cost of miniaturized date transmission unit	$2000.00
Assumptions:	
Usable life span of 5 yr	
20% Idle time between patients	
1 Test per week (42 per year or 208/5 yr)	
Repairs and transducer replacement costs	+144.00
Cost of NST per unit ($2144/208 for 5 yr)	10.30
Professional fee changed by hospital for reading test	
Approximately one half amount currently charged for outpatient NST because no overhead and technical fee are involved	+59.00
Total cost of NST	$69.00
In-hospital program	
Cost of regular fetal monitor	$4000.00
Assumptions	
Usable life span of 5 yr	
3 per day × 180 days/yr (540 per year or 2700/5 yr)	
Repair and transducer replacement costs.	+502.00
Cost of NST per unit ($4502/2700 for 5 yr)	1.67
Professional fee charged by hospital (includes overhead and technical and professional fees)	+118.00 $120.00
Total cost of NST	$121.67
Additional costs not computed may include:	
Nurse at least 0.5 full-time equivalent for in-hospital program versus nurse at least 0.25 full-time equivalent for at-home program	
Room rental cost or 15 × 15 ft room at $12/sq ft ($2700/yr) (excluding heating, cooling, linen, etc.)	
Cost to the patient	
Lost time from work	
Cost of parking and gas	

showed that using Xerox 400 telecopiers to transmit fetal monitoring data to tertiary centers resulted in an improved ability of the medical staff to make accurate and reliable diagnoses. The Xerox method, however, had major disadvantages, including a limit of 8-minute transmission time and a lack of clarity.

Recently, Vintzileos et al.[3] reported the use of a system that permitted direct transmission by medical personnel of antepartum or intrapartum FHR tracings by a telephone line. By using this option, the authors concluded that it allowed the obstetric staff of smaller community hospitals to obtain an immediate consultation and thus improve the quality of perinatal care. In light of the established use of transmission of FHR tracings and the known ability of mothers to conduct a variety of medical self-tests, including uterine activity monitoring, the possibility of patients performing self-NST and transmitting these tracings to a medical facility seemed attractive. For this reason the current study was initiated.

The results of this study demonstrate not only that it was feasible for mothers to perform antepartum FHR testing on their own fetuses but also that the tracings generated were satisfactory for clinical interpretation. Tracings obtained by either patients or medical personnel were indistinguishable for their accuracy and interpretability. In addition, cost analysis reveals a twofold reduction in cost when this form of fetal testing is used. Previous studies reported on FHR monitoring by telephone have clearly shown that the method functions effectively[2, 6, 8]; however, the current study is the first controlled trial in which self-NST was compared with assisted NST and showed that they are comparable.

In conclusion, this new method of antepartum FHR testing, if used within a structured clinical context, will not only provide accurate and reliable information about fetal well-being but offer patients convenience and the potential for reduced medical costs without compromising the results of fetal testing.

Angiographic embolization in the management of hemorrhagic complications of pregnancy

William M. Gilbert, MD,[a] Thomas R. Moore, MD,[a] Robert Resnik, MD,[a] John Doemeny, MD,[b] Homer Chin, MD,[a] and Joseph J. Bookstein, MD[c]

San Diego, California

Obstetric hemorrhage continues to be a major cause of maternal mortality and morbidity. Recent developments in percutaneous angiographic embolization techniques have afforded the ability to control persistent bleeding from pelvic vessels while avoiding the morbidity of surgical exploration. We report the use of angiographic embolization in 10 cases of pregnancy-related hemorrhage, including persistent postcesarean bleeding (three cases), vaginal wall hematomas (four cases), cervical ectopic pregnancies (two cases), and postpartum bleeding as a secondary complication of uterine myomas (one case). The embolization procedures were successful in all cases. Nine of 10 patients experienced postprocedural fever with eight cases resolving with antibiotic therapy alone and one patient requiring vaginal drainage of the hematoma-abscess. The mean length of time for the procedure was 167 minutes (range 70 to 270). The average length of hospitalization was 8 days (range 2 to 13). These data indicate that angiographic embolization is effective in treating hemorrhagic complications of pregnancy in hemodynamically stable patients and is preferable to surgery in selected cases. (Am J Obstet Gynecol 1992;166:493-7.)

Key words: Angiographic embolization, hemorrhage, pregnancy

Obstetric hemorrhage remains one of the three main causes of maternal death in spite of modern blood banks, anesthesia, and pharmacologic agents to treat such complications. Effective management requires prompt identification of the cause and usually responds to one of several targeted conservative modalities, such as oxytoxics, blood component therapy, and careful surgical technique. However, persistent bleeding may occur after the evacuation of a vaginal hematoma or cesarean hysterectomy and may also result from postpartum uterine atony associated with myomas. Cervical ectopic pregnancies, although rare, represent a particularly challenging problem of hemostasis, particularly if unrecognized before curettage.

Hypogastric artery ligation has traditionally been the surgical approach when exploration and arterial ligation prove unsuccessful. With the development of radiographic arterial embolization techniques, an alternative to exploratory surgery or hypogastric artery ligation has become available. The use of angiographic embolization to control hemorrhage has been well described in patients with gynecologic cancer and postpartum vaginal wall hematomas.[1-6] However, in spite of the availability of this technique in many hospitals throughout the United States, it is not widely used on most obstetric services. In this study we report our experience with angiographic embolization in various clinical hemorrhagic settings to emphasize its use as compared with hypogastric artery ligation.

Material and methods

Between July 1984 and December 1990, 10 patients at the University of California at San Diego Medical Center and Mercy Hospital and Medical Center required angiographic embolization to control obstetric hemorrhage. All hospital records were reviewed and detailed to collect pertinent clinical data pertaining to the specific leading complication, clinical status, blood replacement requirements, length of embolization procedure, and complications. Two of these cases (7 and 8, Table I) have been reported previously.[1]

Angiographic consultation and intensive care facilities are available on a 24-hour basis at both of these hospitals. Several patients were referred to our institutions from outside hospitals where these embolization techniques were not available. All patients with hemorrhagic complications unresponsive to conservative management were stabilized and taken to the radiology suite for the angiogram and embolization. By the percutaneous approach with the patient under local anesthesia, an aortogram was performed for identification of the pelvic arterial anatomy and bleeding sites. A variety of catheter shapes can then be used to enable selective catheterization of the bleeding artery, but one

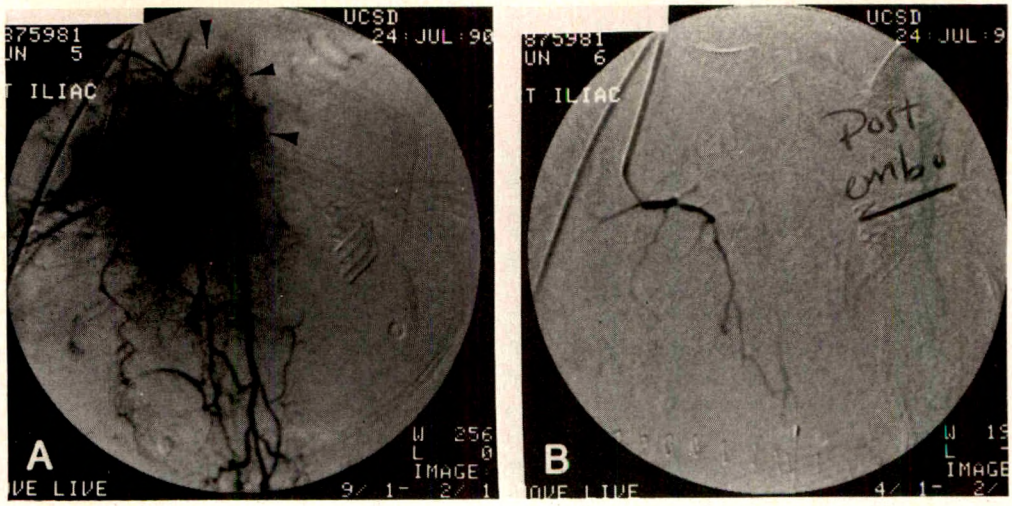

Fig. 1. A, Preembolization arteriogram demonstrates free bleeding in area of vaginal cuff after cesarean hysterectomy for uterine atony (case 6). This free bleeding is described as "blush" *(arrows)* and demonstrates significant bleeding. **B,** Postembolization film demonstrates complete blockage of hypogastric artery on right after the Gelfoam injection.

of us (J.J.B.) strongly recommends the long-reversed-curved catheter of Cordis (Cordis Inc., Miami). Subselective embolization of the bleeding vessel was then performed, usually with small pieces (2 × 2 × 2 mm) of Gelfoam (Upjohn, Co., Kalamazoo), through the catheter. Gelfoam is a gelatin sponge that is slowly absorbed and ultimately enables recanalization of the embolized vessel. Hemostasis was documented by fluoroscopic monitoring. If bleeding continued, further embolization was performed until the bleeding stopped. The catheter was then switched to the opposite hypogastric artery and the same procedure as above was performed to provide hemostasis if needed. A final aortogram was performed to document overall hemostasis and to exclude the possibility of continued bleeding from collateral sources. If necessary, collaterals themselves were then embolized.

Results

A summary of the 10 patients requiring embolization is shown in Table I. The average length of the angiographic procedure was 167 minutes (range 70 to 270).

Table I. Ten cases of angiographic embolization

Case No.	*Gestational age (wk)*	*Diagnosis*	*Length of procedure (min)*	*Blood*	*Complications*	*Hematocrit (%)*	*Procedure*	*Length of stay (days)*

PRBC, Packed red blood cells. Cases 6 and 8 had two angiographic embolizations performed on separate days.

The time of the procedure is recorded from that time the patient was sent to the angiographic unit until her return to the obstetric or intensive care unit. However, the time required to control bleeding usually is much shorter (but less well documented) and was only 25 minutes from start of procedure to control of bleeding in case 10. The primary complication included postprocedural fever in nine of 10 cases, eight of nine responding to antibiotics alone, whereas in case 7 vaginal drainage of a paravaginal abscess cavity was required 8 days after radiographic embolization. Seven of 10 patients required blood transfusions before or after the procedure, and the other three patients refused blood products (cases 3, 7, and 9).

In case 6 the patient had undergone a cesarean hysterectomy because of uterine atony associated with a triplet delivery. The estimated blood loss during and after surgery was 3000 ml, and the patient was transfused with 18 units of packed red blood cells and multiple units of fresh-frozen plasma. The patient continued to experience vaginal bleeding after surgery and was taken to the radiology suite where angiography revealed bleeding in the area of the vaginal cuff, as demonstrated by the dye "blush" outlined by the arrows in Fig. 1, *A*. Bilateral hypogastric artery embolization was accomplished (Fig. 1, *B*), and adequate hemostasis was felt to have been obtained. However, the patient continued to have bleeding from drains and underwent

a second angiogram the following day to determine whether the ovarian arteries could be a possible source for the continued bleeding. Embolization of the right ovarian artery was successful in obtaining hemostasis.

In case 3 the patient underwent a normal vaginal delivery and was found to have continued bleeding in spite of a firm, well contracted uterus and postpartum curettage. The patient was known to have myomas. She underwent angiograms which revealed uterine bleeding. Embolization of the anterior division of both hypogastric arteries was successful in stopping the hemorrhage.

The patient described in case 10 was transferred after a traumatic forceps delivery, which resulted in an expanding left vaginal hematoma. In Fig. 2, *A*, the hematoma is outlined by the arrows. Embolization was directed into the left hypogastric artery, and follow-up x-ray films (Fig. 2, *B*) reveal that the bleeding has stopped. Two days later the patient was taken to the operating room, where the hematoma was uneventfully drained. The patient did quite well and went home on the eleventh hospital day.

Case 8 involved a patient who presented with signs of severe pregnancy-induced hypertension and possible fatty liver of pregnancy, including liver failure and disseminated intravascular coagulation. After a forceps delivery, an expanding hematoma that was noted on the left vaginal wall did not respond to conservative exploration and packing. The patient was subsequently transferred to our institution where additional conservative treatment, including two additional attempts at vaginal packing, was unsuccessful. The patient then underwent embolization of the left and right hypogastric arteries, which initially controlled the bleeding. However, because of recurrent hemorrhage into the paravaginal space and the question of a retroperitoneal hematoma, she had a second procedure that embolized the remaining vessels of the left hypogastric artery and right ovarian artery.

Comment

These cases illustrate the role of angiographic embolization as an alternative to surgery for the treatment of obstetric hemorrhage from a variety of causes. Angiographic embolization prevented the need for a general anesthetic, allowed the preservation of reproductive capability, and prevented reexploration in those patients who had undergone surgery. The complications related to the procedure were minimal and included postprocedural fever, which responded to antibiotic therapy, and transient buttock pain, which resolved over time. Angiographic embolization has been reported effective at stopping arterial hemorrhage in >90% of cases of gynecologic hemorrhage because of the ability to place the embolic material within the hypogastric artery.[7, 8] In our cases, success was achieved after the first attempt at embolization in eight of 10 cases, whereas an additional procedure to produce hemostasis was necessary in two cases.

Hypogastric artery ligation is often recommended as the primary conservative surgical procedure to control hemorrhage in similar complications. The primary goals of hypogastric artery ligation are to preserve reproductive function and to offer less morbidity than more definitive surgery. Clark et al.,[9] however, found that hypogastric artery ligation was successful in only eight of 19 (42%) patients with obstetric hemorrhage. Bleeding failed to stop in the remaining 11 patients, and hysterectomy was required.[9] Furthermore, those patients in that series who underwent hysterectomy as the primary procedure had substantially less morbidity than those who underwent hypogastric artery ligation and hysterectomy. Hypogastric artery ligation decreases arterial pulse pressure by 85% distal to the ligation but decreases blood flow in these distal vessels by only 48%.[10] The extensive collateral circulation in the pelvis maintains a significant blood flow in spite of the ligation. This may well account for the low success rate of hypogastric ligation in providing adequate hemostasis. Embolization, however, enables specific obstruction of the bleeding vessel and produces obstruction beyond entry of large collaterals. Angiographic embolization must be considered before hypogastric artery ligation, because once the artery is ligated, embolization cannot be performed.

Obstetric hemorrhage can often be extremely rapid, with exsanguination and death occurring within minutes. In these emergency cases the patient must be stabilized and the bleeding stopped by the most rapid and complete method possible. If conservative methods such as applied pressure or packing are sufficient to provide temporary hemostasis, the patient may be stabilized with intravenous fluids, blood replacement, and clotting factors, if indicated. Resuscitation status is monitored by measuring the arterial blood gas and base excess, hematocrit, and urine output. If a coagulopathy is present, it should be corrected before or during embolization. The angiographic team should be consulted early in the course of a hemorrhagic complication to allow time for the team to arrive and prepare to treat the patient. Complications associated with angiographic embolization include embolization of an inappropriate vessel or ischemia distal to the embolization. These complications are rare because of the rich collateral blood supply in the pelvis. In our cases fever occurred in nine of 10 cases. All but one responded to antibiotic therapy alone, whereas one case required vaginal drainage of an abscess 8 days after the embolization.

Angiographic embolization should also be consid-

ered in cervical ectopic pregnancy or if bleeding ensues when this complication has gone unrecognized. Under optimal circumstances, consideration should be given first to the use of new treatment modalities, such as methotrexate, to treat such ectopic gestation.[11, 12]

Our experience demonstrates that angiographic embolization is a safe, effective, and relatively rapid procedure that should be considered early in the course of obstetric hemorrhage that is unresponsive to conservative management. If the patient is hemodynamically stable, the procedure should be performed before hypogastric artery ligation or hysterectomy.

Breech extraction of low-birth-weight second twins: Can cesarean section be justified?

Lisa Davison, MD,[a] Thomas R. Easterling, MD,[a] J. Craig Jackson, MD,[b] and Thomas J. Benedetti, MD[a]

Seattle, Washington

The outcomes of 54 breech-extracted second twins weighing between 750 and 2000 gm were compared with the outcomes of their siblings and of 43 sets of twins delivered by cesarean section for malpresentation. Vaginally delivered first twins had fewer days of mechanical ventilation and oxygen therapy than their breech-extracted siblings ($p = 0.004$). There were no significant differences in any measures of neonatal outcome when breech-extracted twins were compared with second twins delivered by cesarean section. We conclude that routine cesarean section is not justified for nonvertex second twins expected to weigh <2000 gm. (Am J Obstet Gynecol 1992;166:497-502.)

The optimal route of delivery for low-birth-weight vertex and nonvertex twin pairs is a matter of obstetric controversy. The incidence of such pairings is between 38% and 51% and is inversely related to gestational age.[1-3] Although there is evidence to support the safety of vaginal delivery with breech extraction of the second

twin for those with birth weights >1500 gm,[4-6] there are few reports with specific data regarding the management of lower birth weight twins.

Since 1979 many of the obstetricians at University of Washington Medical Center have chosen to manage the delivery vertex and nonvertex twin pairs by vaginal trial with breech extraction of the second twin, regardless of estimated birth weight.

The purpose of this retrospective study was to evaluate morbidity and mortality in low-birth-weight breech extracted second twins and to determine whether routine cesarean section is justified in this group.

Material and methods

We hypothesized that breech extraction of low-birth-weight second twins is not associated with excess morbidity or mortality sufficient to justify routine cesarean section for nonvertex presentation of a second twin. To test this hypothesis we identified a population of second twins delivered by breech extraction and compared their outcomes with the outcomes of their twin siblings and the outcomes of a comparable population of second twins delivered by cesarean section for the indication of malpresentation. Since both infants within a twin pair are usually managed by the same route of delivery, we also compared the outcomes of all twins (As and Bs) delivered vaginally with the outcome of all twins (As and Bs) delivered by cesarean section.

Charts of women delivering at the University of Washington Medical Center between July 1979 and March 1990 were reviewed to identify twin pairs with both infants born alive, without serious congenital anomaly, and weighing between 750 and 2000 gm. The study groups thus consisted of vaginally delivered twin pairs in which breech extraction was performed for the second twin and twin pairs delivered by cesarean section for malpresentation of the first or second twin.

Data were collected by chart review and from the neonatal data base. Measures of neonatal outcome were survival rates; the incidence of intracranial hemorrhage grades III and IV[7]; necrotizing enterocolitis; infant respiratory distress syndrome; and the duration of hospitalization, mechanical ventilation, and oxygen therapy.

In the cases in which twin A was delivered vaginally and twin B underwent total breech extraction, deliveries were performed under double set-up conditions by a resident with supervision by a faculty member. Pediatricians were present for neonatal resuscitation.

Table II. Neonatal outcome by delivery mode (mean ± SD)

	Vaginal A and B	*Cesarean A and B*	*p*
N	108	86	
Birth weight (gm)	1415 ± 334	1394 ± 328	NS
Gestational age (weeks)	30.2 ± 2.6	30.1 ± 2.5	NS
Survival	96 (89%)	79 (92%)	NS
Infant respiratory distress syndrome	68 (63%)	53 (62%)	NS
Necrotizing enterocolitis	7 (6.5%)	4 (5.8%)	NS
Severe intracranial hemorrhage	10 (9.3%)	10 (12%)	NS

NS, Not significant ($p < 0.05$).

The mother had anesthesia, usually epidural, for pain control and to facilitate manipulation. After spontaneous vaginal delivery of twin A, twin B's presentation was determined by real-time ultrasonography, and total breech extraction was initiated immediately, according to standard techniques.[8]

The data were analyzed by the Student *t*, χ^2, Fisher's exact, Wilcoxon, and Mann-Whitney tests.

Results

Over the 10-year period, 201 twin pairs met initial study criteria. Delivery modes are outlined in Table I. In 54 pairs, vaginal delivery of the first twin was followed by breech extraction of the second twin. In 43 pairs, cesarean section was performed for malpresentation of one or both twins. These two sets of twins were the subjects of the study.

We excluded from consideration the 58 twin pairs in which both twins were vertex and had spontaneous vaginal deliveries, and the 38 pairs delivered by cesarean section for maternal or fetal medical indications such as distress, hypertension, bleeding, or cord prolapse. We also excluded the eight pairs in which twin A was delivered vaginally and twin B required emergency cesarean section. In four cases, the second twin was vertex and was delivered by cesarean section due to abruptio placentae (two) or failure to descend (two). In three cases, external version of the second twin was unsuccessfully attempted, and breech extraction was not considered as a management option. In one case, breech extraction was not undertaken because the cervix was found to be only 8 cm dilated after delivery of the first twin.

Four groups of infants were compared: breech-extracted second twins (vaginal Bs), their siblings (vaginal As), and the twins delivered by cesarean section for presentation (cesarean As and cesarean Bs). Breech-extracted infants were compared both with their siblings and with second twins delivered by cesarean section. The vaginally delivered twins were also compared as a group with those delivered by cesarean section.

There were no cases of birth trauma (e.g., brachial nerve palsy), fracture, or head entrapment. None of the infants were growth-retarded. Birth weights were equally distributed among the study groups (Fig. 1). There were no differences in survival, mean birth weight, or gestational age or in the incidence of infant respiratory distress syndrome, necrotizing enterocolitis, or severe intracranial hemorrhage among infants grouped by route of delivery only (Table II). Table III displays similar data with infants grouped by route of delivery and birth order; there were no significant differences among the groups in any of these variables, except that second twins delivered by cesarean section (cesarean Bs) had a greater incidence of infant respiratory distress syndrome than their siblings (cesarean As) ($p = 0.05$).

Duration of mechanical ventilation, oxygen therapy, and hospitalization were nonparametrically distributed and are displayed graphically in Figs. 2 and 3. In these figures, the percentile rank of each infant is plotted against the outcome variable. When infants were grouped by route of delivery only (Fig. 2), there were no differences in morbidity. When infants were grouped by route of delivery and birth order (Fig. 3), paired tests were used when siblings were compared. Breech-extracted second twins (vaginal Bs) were found to have a significantly greater duration of mechanical ventilation and oxygen therapy than vaginally delivered first twins (vaginal As) ($p = 0.004$). When breech-extracted second twins were compared with second twins delivered by cesarean section, no significant differences were found.

Results were unchanged when data were analyzed to exclude infants who weighed >1500 gm. The incidence of infant respiratory distress syndrome in vaginal Bs was 81.3% compared with 80% for cesarean Bs ($p = 0.80$). The incidence of grade III or IV intracranial hemorrhage was 12.5% compared with 20% ($p = 0.60$). The survival rates were 82% compared with 90% ($p = 0.53$). The results also were unchanged when nonsurvivors were excluded.

Comment

Breech extraction for second twins with birth weights >1500 gm has not been associated with increased neo-

*Breech extracted.

natal morbidity or mortality.[4-6] Cesarean section has not been recommended for infants of this birth weight category.

Breech extraction of second twins weighing <1500 gm has not been well studied. Chervenak et al.[6] reported 76 breech-extracted second twins of whom 16 weighed <1500 gm; they found that delivery mode was not associated with any difference in outcome. Nevertheless, they recommended routine cesarean section for breech infants with birth weights <1500 gm. Barrett et al.[9] found that breech-extracted second twins weighing <1500 gm had lower Apgar scores and increased neonatal morbidity when compared as a group with their first born siblings. This difference was not found among twins delivered by cesarean section. Although comparisons were not made between second twins delivered vaginally and those delivered by cesarean section, the authors recommended routine cesarean section be undertaken for nonvertex twins expected to weigh <1500 gm.

We found that vertex first twins delivered vaginally (vaginal As), required fewer days of mechanical ventilation and oxygen therapy than second twins who were delivered by breech extraction (vaginal Bs). This is consistent with Barrett et al.'s findings that first twins have fewer complications than their siblings.[9] However, we found no differences between second twins delivered by breech extraction (vaginal Bs) and second twins delivered by cesarean section (cesarean Bs) (Table III and Fig. 3). The outcomes of second twins delivered by breech extraction were comparable to the outcomes of first and second twins delivered by cesarean section. The differences observed among the four groups seem to be attributable to an improved outcome associated with labor and vaginal delivery for vertex first twins.

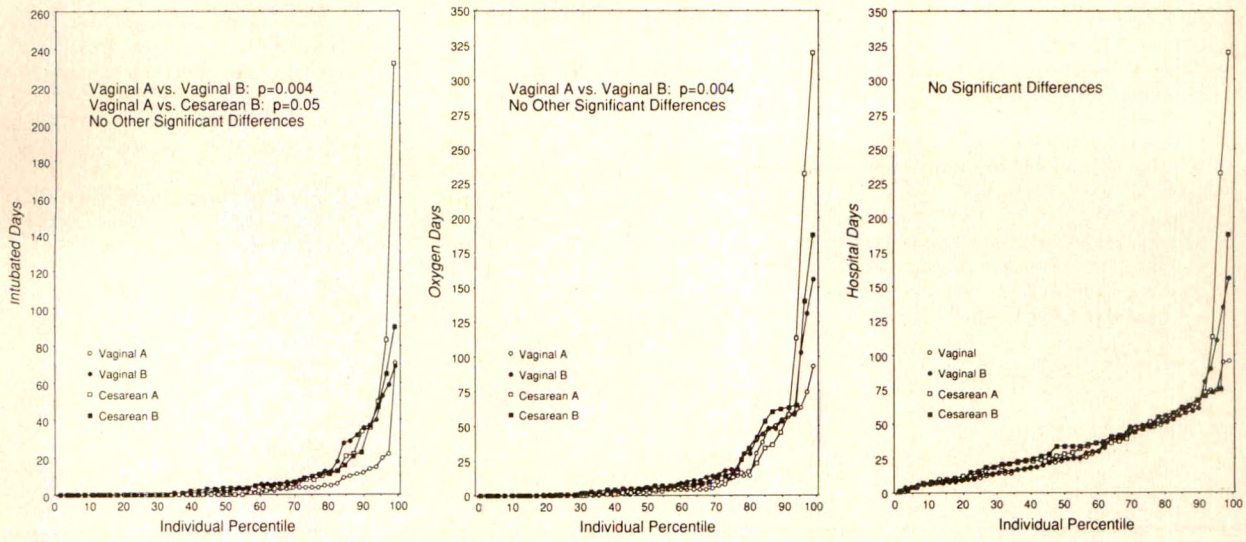

Fig. 3. Duration of mechanical ventilation, oxygen therapy, and hospitalization by route of delivery and birth order. Duration of therapy for each infant is plotted against infant's percentile rank within its group. Percentile ranks are used to adjust for unequal sizes of groups.

Figs. 2 and 3 permit a careful inspection of the performance of the individuals in each group and a visual comparison of the groups as a whole. The data are presented in this fashion because they are not parametrically distributed; means and standard deviations would not be appropriate. When significant differences do exist, they are due to differences in the most severely affected fourth of the subjects. Therefore, in spite of high levels of significance between some groups, the medians of these are nearly identical. Finally, the nonparametric nature of the data precludes an estimate of power. When comparisons are not significant, the reader can see that the outcome curves are superimposed and that the probability is small that clinically significant differences could be found with a larger sample size.

In Fig. 2, which compares infants by route of delivery alone (vaginal As and Bs compared with cesarean As and Bs), the curves are nearly indistinguishable. When twins were compared by birth order and route of delivery, first twins delivered vaginally (vaginal As) were found to require significantly fewer days of mechanical ventilation than their breech-extracted siblings (vaginal Bs). The curves for the other three groups of infants are nearly indistinguishable. When duration of oxygen therapy is considered, first twins delivered vaginally required less therapy than breech-extracted infants. However, inspection of the curves suggests that the differences which are statistically significant may be too small to be clinically significant.

The weaknesses of a retrospective study design are well known, but a randomized, controlled trial of the effect of breech extraction on the neonatal outcome of low-birth-weight second twins is impractical. However, we compared a relatively large number of breech extracted second twins with their siblings and with second twins delivered by cesarean section. The nonsignificant differences we observed are trends toward decreased morbidity for the vaginally delivered twins. This suggests that, although an even larger study group might be needed to avoid a type II error, we have probably not failed to detect any tendency toward an increase in morbidity attributable to breech extraction. By excluding from consideration those twin pairs delivered by cesarean section for medical indications other than presentation, we have avoided the possibility of introducing a bias toward worse neonatal outcomes in the cesarean section group.

Cesarean section is an intervention that should not be undertaken without justification on the basis of an objective risk-benefit analysis. We were unable to demonstrate that cesarean section improved neonatal outcome when breech-extracted second twins were compared with second twins delivered by cesarean section. In addition, vaginal delivery was associated with an improved outcome for vertex first twins. We therefore conclude that routine cesarean section is not justified for nonvertex second twins expected to weigh <2000 gm.

Cervical stenosis in pregnancy: A complication of cryotherapy in diethylstilbestrol-exposed women

Charles Kalstone, MD

Miami, Florida

Cryotherapy causes a high incidence of cervical stenosis in diethylstilbestrol-exposed women because of an abnormal healing response. Consequently, the cervix may not dilate during labor, necessitating cesarean section. To prevent this, therapy should be localized to the abnormal tissue on the cervix instead of the entire transformation zone whenever possible. (Am J Obstet Gynecol 1992;166:502-3.)

Key words: Cryotherapy, diethylstilbestrol, cervical stenosis, cervical dystocia

Two cases are reported in which cervical stenosis was diagnosed during labor in diethylstilbestrol (DES)-exposed women who previously had cryotherapy for cervical intraepithelial neoplasia.

Case reports

Case 1. A 25-year-old DES-exposed woman had cryotherapy for grade 1 cervical intraepithelial neoplasia 18 months previously. On her initial examination during pregnancy, the cervix appeared short and broad; the external os was not well defined.

She was admitted at term, 1 hour after spontaneous rupture of the membranes, with painful uterine contractions every 2 minutes. The cervix was difficult to outline. It felt like there was a small dimple in the middle of the vaginal apex, and the lower uterine segment was pushed downward ahead of the vertex, which was engaged. The cranial sutures could be palpated through the thin lower uterus.

Speculum examination demonstrated amniotic fluid coming from the top of the vagina but no cervical os was visualized. The anterior cervix appeared edematous, as if fluid had been injected underneath the mucosa.

Painful uterine contractions continued, consistent with active labor. Cervical stenosis was suspected, so a low transverse cesarean section was done with the patient under epidural anesthesia. The 7-pound 10-ounce male infant had marked molding. The lower uterine segment was very thin. From above, the internal os felt just like a dimple. A small hemostat could be passed through it into the vagina. During this, it was evident that the cervix had effaced completely.

At examination 6 weeks post partum the cervix was still difficult to outline distinctly, although it was possible to obtain a cervical cytologic sample, including endocervical brush sampling. Severe dysmenorrhea, which was present before cryotherapy, was relieved by oral contraceptives.

Case 2. A 31-year-old DES-exposed woman had

6/1/33385

cryotherapy for grade 1 cervical intraepithelial neoplasia. On the initial pregnancy examination 6 years later, the cervix did not appear abnormal.

Labor started at 39 weeks. After 2 hours of regular contractions, the external os was a dimple and could not be entered by digital examination. The uterine contractions became painful and continued every 5 minutes for 9 hours. The external os did not dilate. The vertex was at −2 station, well applied to the cervix. Cervical stenosis was diagnosed, and a low transverse cesarean section was done with the patient under epidural anesthesia. The 8-pound 4-ounce female infant had some molding. The lower uterine segment was very thin. The cervical os could not be probed from above with a finger or a narrow curved clamp.

At examination 6 weeks post partum the cervix did not appear abnormal. Dysmenorrhea, which was present before and after cryotherapy, was minimal after childbirth.

Comment

The effects of in utero DES exposure on the reproductive tract have been well described. They include structural abnormalities of the uterine corpus and cervix that can lead to spontaneous first-trimester and midtrimester abortion and preterm labor.

In managing the labors of the cases reported above, clinically there was no question that there was cervical stenosis and that cesarean section was necessary. I have managed other cases in which cervical stenosis caused dystocia in labor, such as conglutination after abortion attempts with potassium permanganate or from scarring due to previous conization. The cervix effaces as the internal os and canal are drawn upward around the head by the uterine contractions, but the external os remains a dimple and the lower uterine segment balloons downward into the vagina, ahead of the presenting part. In some of these cases the cervix can be dilated with a uterine dressing forceps and then labor can continue normally.

In these two cases it was assumed that the cervical stenosis was related to the DES exposure and cryotherapy. The incidence of cervical stenosis associated with cryotherapy in patients exposed in utero to DES is 75% to 85%.[1] Cryotherapy is usually a low-risk procedure. However, in DES-exposed women there is an abnormal healing response of the cervix to cryosurgery or conization.[2] In these two patients the freeze, which was done with the short-tip exoprobe, was shallow, involving only the external os and not much of the cervical canal, so they had no difficulty conceiving.

The unique aspect of these cases is that they demonstrate the effect that in utero DES exposure plus cryotherapy can have on the ability of the cervix to dilate during labor. When treating cervical intraepithelial neoplasia in DES-exposed patients who desire children, one should consider locally destructive procedures such as laser aimed at treating the demonstrable dysplastic tissue, if possible, rather than the entire transformation zone.[1, 2]

DES-associated problems represent a unique occurrence in medicine in that they will become obsolete. In the meantime we must continue to deal with their consequences. This report adds one more potential obstetric complication.

I thank J. Robert Willson, MD, Professor, Department of Obstetrics and Gynecology, University of New Mexico School of Medicine, Albuquerque, New Mexico, for his assistance.

Meta-analysis of surgery in advanced ovarian carcinoma: Is maximum cytoreductive surgery an independent determinant of prognosis?

R. William Hunter, MBBS, Neal D.E. Alexander, DipMathStat, and W. Patrick Soutter, MD

London, England

OBJECTIVE: If maximum cytoreductive surgery benefits the survival of women with advanced ovarian cancer, the median survival time of groups of such women will improve as the proportion of women undergoing maximum cytoreductive surgery is increased.

STUDY DESIGN: Fifty-eight suitable studies that encompass 6962 patients with advanced ovarian cancer were identified. Multiple linear regression was used to analyze the effects on median survival time of the following variables: the proportion of each cohort undergoing maximum cytoreductive surgery, the use of platinum-containing chemotherapy, the dose intensity of chemotherapy, the proportion of each cohort with stage IV disease, and the year of publication of the study.

RESULTS: Maximum cytoreductive surgery was associated with only a small improvement in median survival time, but platinum-containing chemotherapy improved median survival time substantially. Increased dose intensity also conferred a useful survival benefit.

CONCLUSION: Cytoreductive surgery probably has only a small effect on the survival of women with advanced ovarian cancer. The type of chemotherapy used is more important. (Am J Obstet Gynecol 1992;166:504-11.)

Key words: Maximum cytoreductive surgery, advanced ovarian carcinoma, prognosis, chemotherapy

Most ovarian cancer is first seen as advanced intraabdominal disease. Complete surgical extirpation can rarely be achieved and current management consists of maximum cytoreductive surgery to reduce tumor residuum to a minimum, followed by chemotherapy. Cytoreductive surgery appears to contravene traditional principles of cancer surgery because disease-free margins are rarely obtained. Prospective randomized studies to evaluate the benefit of primary maximum cytoreductive surgery have not been performed.

Both response to chemotherapy and survival are related to the volume of residual disease after surgery.[1-3] Patients with advanced disease debulked to a residuum of <1.5 cm diameter have the same prognosis as patients whose disease was <1.5 cm in diameter before intervention.[4] On the basis of these data, current surgical practice aims to leave the smallest residuum possible. However, the better prognosis of women with minimal residual disease may be due to their having less aggressive tumors rather than being an effect of the surgery itself. The different reported rates of maximum cytoreductive surgery vary widely, reflecting the determination and surgical experience of some and the scepticism regarding the need for such extensive surgery by others.

If maximum cytoreductive surgery is responsible for improving the prognosis in ovarian cancer, the median survival of the whole group should be greater in those series containing a high percentage of patients undergoing maximum cytoreductive surgery than in those series with a low rate.

Methods

Selection of studies. A literature search of *Medline* was performed for publications under the headings "ovarian cancer," "ovarian carcinoma" and "ovarian neoplasms," from 1976 to 1989, and in the *Index Medicus* under the heading "ovarian neoplasms" from 1967 to 1989. In addition, unpublished data from the third North Thames Ovarian Cancer Trial and from a multicenter study run by the Cancer Research Campaign Trial Office in Glasgow were included.

Studies were selected if they were composed of patients with predominantly stage III and stage IV ovarian cancer and if the overall median survival time and proportion of patients undergoing maximum cytoreductive surgery were shown. Many studies were unsuitable because median survival time was not stated for the group as a whole but only for patients who underwent successful surgery. The following was re-

corded for each cohort: total number of patients, percentage of stage III cases, percentage of stage IV cases, percentage of maximum cytoreductive surgery, dose intensity of chemotherapy, median survival time, use of platinum-containing chemotherapy, and year of publication.

Maximum cytoreductive surgery was defined in terms of residual disease as follows: in 78.4% of the cohorts as <2 cm in diameter, in 5.2% as <3 cm, in 4.1% as <1.5 cm, in 2% as <1 cm, and in 10.3% by a verbal description such as "no palpable residual tumor."

Assessment of chemotherapy. To make allowance for chemotherapy regimens of differing effectiveness, all regimens were classified as either platinum-containing or non-platinum-containing. In addition, the potency of the chemotherapy was quantified as dose intensity because this method has already been shown to correlate with median survival time of patients with advanced ovarian cancer.[5] Calculation of dose intensity was only possible for regimens containing the following drugs, either singly or in combination: cisplatin, cyclophosphamide, hexamethylmelamine, doxorubicin, melphalan, and chlorambucil. Dose intensity was calculated as previously described.[5]

Statistical methods. The data are summarized in Table I. The effect on median survival time of the following six variables was investigated by multiple linear regression: percent stage III, percent stage IV, percent maximum cytoreductive surgery, dose intensity, year of publication, and whether the patients received platinum-containing chemotherapy. The regression was weighted by the number in each cohort, thus tending to give larger studies more influence than smaller ones. The variability of median survival time was found to increase with median survival time itself, which invalidates regression analysis. This was resolved by logarithmic transformation of the data, which is equivalent to looking at proportional rather than absolute changes in median survival time. Anscombe's test[60] was used to confirm objectively that this problem had been resolved. The deviations of the actual from the predicted median survival time were also found to have a normal distribution after logarithmic transformation, as confirmed by the Shapiro-Francia W′ test[61] and as required for the analysis. Results are quoted as two-sided p values and 95% confidence intervals, and p values <5% are described as statistically significant. The analysis was carried out using the Minitab software package.[62]

Results

A total of 58 separate studies, containing 97 cohorts and 6962 patients, was identified. Of the 97 cohorts, 76 could be ascribed a dose intensity. Without taking into account the possible effects of the chemotherapy used or the percent stage IV cases, there does seem to be an association between the percent maximum cytoreductive surgery and median survival (Fig. 1). Each 10-point increase in percent maximum cytoreductive surgery was associated with an estimated 16.3% increase in median survival time (95% confidence interval 10.4% to 22.5%, $p < 0.001$). A plot using only the cohorts for which dose intensity could be calculated gave a very similar regression, indicating that these 76 were very likely to be representative of the whole study population.

Multiple linear regression of log median survival time on percent stage IV, dose intensity, use of platinum, and percent maximum cytoreductive surgery was performed (Table II). Each 10-point increase in percent stage IV was associated with an estimated 2.6% decrease in median survival time (95% confidence interval 0.1% to 5.0%, $p = 0.038$). Each increase of 0.2 unit in dose intensity was associated with an estimated 11.1% increase in median survival time (95% confidence interval 6.0% to 17%, $p < 0.001$), and use of platinum was associated with an estimated increase of 53% in median survival time (95% confidence interval 35% to 73%, $p < 0.001$). Each 10-point increase in percent maximum cytoreductive surgery was associated with an estimated 4.1% increase in median survival time (95% confidence interval −0.63% to +9.1%, $p = 0.089$, Fig. 2). There is some evidence of increased percent maximum cytoreductive surgery being beneficial, independent of percent stage IV, dose intensity, and use of platinum, although the size of any effect is relatively small.

Interactions between variables and nonlinear effects were found not to be significant. In particular, there was no evidence that the size of the effect of platinum was dependent on percent maximum cytoreductive surgery ($p = 0.87$). The inclusion of percent stage III and year of publication, in addition to percent stage IV, dose intensity, platinum, and percent maximum cytoreductive surgery, had no significant effect on the analysis ($p = 0.82$ and 0.81, respectively).

Two cohorts had a much larger influence than the rest on this analysis, as measured by "leverage."[61, 62] These were both from reference 14 (Table I). Omitting them from the analysis slightly increases the effect of percent maximum cytoreductive surgery, each 10-point increase in which is then associated with an estimated 4.6% increase in median survival time (95% confidence interval −0.15% to +9.8%, $p = 0.058$).

If the effect of dose intensity is ignored and all 97 cohorts are included in the analysis, the effect of percent maximum cytoreductive surgery was statistically significant ($p = 0.014$) and each 10-point increase in it was associated with a 6.1% increase in median survival time (95% confidence interval 1.3% to 11.2%).

This analysis might be criticized for including all cohorts without regard to which study they were from.

*Harding M, Milsted R, Kaye S, et al. Long term results of cyclophosphamide, Adriamycin and platinum chemotherapy in advanced epithelial ovarian cancer. Unpublished observations.

This assumes that, after allowing for percent maximum cytoreductive surgery, percent stage IV, dose intensity, and platinum, two cohorts from different studies are as alike as two cohorts from the same study. To validate this assumption the analysis was repeated with the use of only the largest cohort from each study. The best model with the use of two predictor variables was that with dose intensity and platinum, and adding none of the remaining four predictor variables gave a significantly better fit. A 10-point increase in percent maximum cytoreductive surgery was associated with only a 2.8% increase in median survival time (95% confidence interval −2.5% to 8.1%, $p = 0.29$). When the effect of dose intensity was ignored and all 97 cohorts were used, the effects of percent maximum cytoreductive surgery, platinum, and year of publication were significant, the last presumably acting as a "proxy" for dose intensity, which has tended to increase over time. In this model a 10-point increase in percent maximum cytoreductive surgery was associated with a 5.9% increase in median survival time (95% confidence interval 0.1% to 11.4%, $p = 0.046$).

Measurement of the size of residual disease is often not accurate and the definition of maximum cytoreductive surgery varies. The effect of changing the definition was examined. In 12 cohorts some patients may have had residual disease >2 cm in diameter. When these were omitted, a 10-point increase in percent maximum cytoreductive surgery was associated with an estimated 5.8% increase in median survival time (95% confidence interval 0.9% to 11.0%, $p = 0.02$). In 21 of the cohorts the percentage of patients left with no residual disease whatsoever was stated. When the multiple linear regression was repeated on the 18 of these for which dose intensity could be calculated and with percent stage IV, dose intensity, platinum, and percent with no residual disease used as predictors, each 10-point increase in percent with no residual disease was associated with an estimated 6.9% increase in median survival time (95% confidence interval −16.0% to 36.0%, $p = 0.56$). This lack of significance could be due to the small number of cohorts, although this did not prevent the other three variables from reaching significance, the p values for percent stage IV, dose intensity, and platinum being

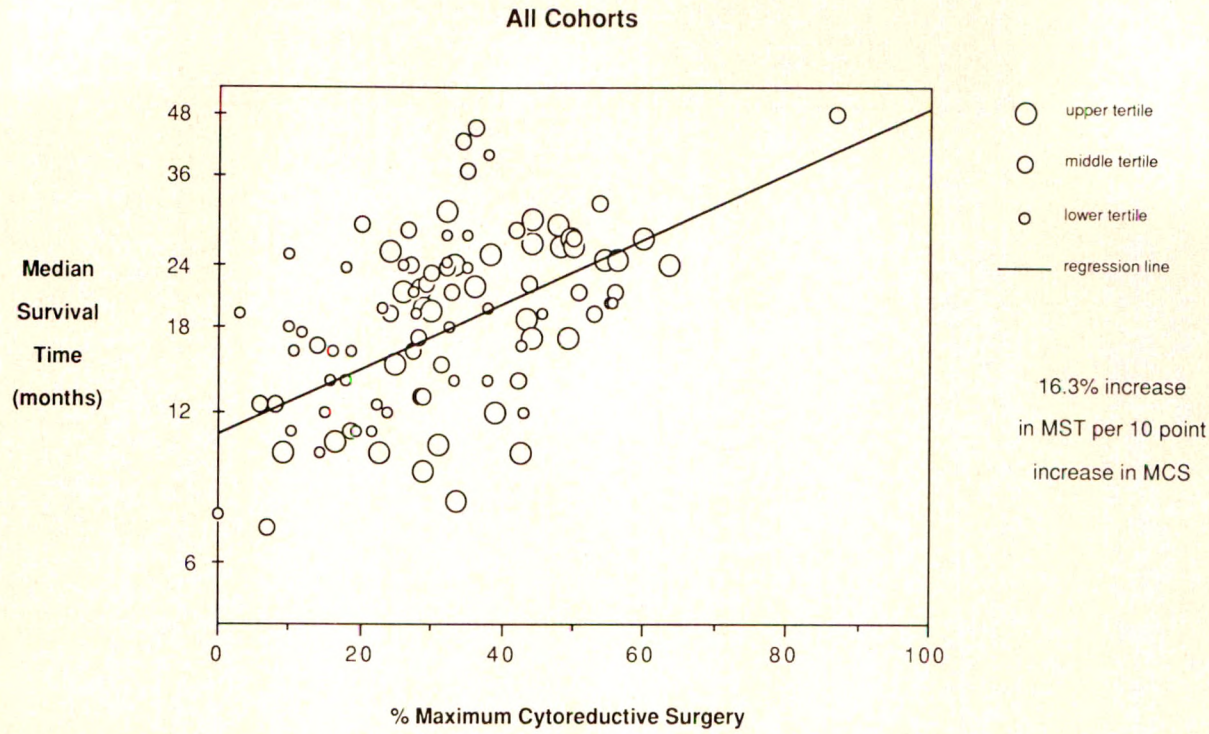

Fig. 1. Graph of log median survival time *(MST)* (months) versus percent maximum cytoreductive surgery *(MCS)* for all 97 cohorts. Effects of chemotherapy and percent stage IV cases are ignored.

Table II. Results of multiple linear regression analysis showing percent increase in median survival time, 95% confidence intervals, and p values associated with different variables

Variable	*Increase in mean survival time (%)*	*95% Confidence interval*	*Significance*
Use of platinum	53.0	35.0% to 73.0%	$p < 0.001$
Dose intensity (each 0.2 unit increase)	11.1	6.0% to 17.0%	$p < 0.001$
Patients with stage IV disease (%) (each 10-point increase)	−2.6	−0.1% to −5.4%	$p < 0.011$
Patients undergoing maximum cytoreductive surgery (%) (each 10-point increase)	4.1	−0.6 to 9.1%	$p = 0.089$

0.025, 0.012, and <0.001, respectively. This suggests that the effect of percent maximum cytoreductive surgery is still small regardless of the precise definition.

Comment

The results of this meta-analysis suggest that only a small improvement in median survival is achieved by maximum cytoreductive surgery in women with advanced ovarian cancer. In contrast, the use of platinum-containing chemotherapy appears to be associated with a much greater prolongation of median survival, confirming the results of Peto and Easton.[63] This substantial survival advantage after platinum may be because platinum agents were not available as second-line therapy in many of the studies. In this data set median survival time was also improved by increasing the dose intensity of chemotherapy, concurring with the findings of Levin and Hryniuk.[5] However, the dose intensity in the older studies in this analysis was very low, so this finding may be less relevant to modern practice.

That surgery should have such a small impact on survival is surprising in view of its well-established role in the primary treatment of advanced ovarian cancer and the importance placed on achieving a high percentage of maximum cytoreductive surgery.[24] The statistical significance of percent maximum cytoreductive surgery is sensitive to the inclusion or exclusion of a very small number of cohorts. However, whether these cohorts are or are not included, the size of any improvement associated with increased percent maximum

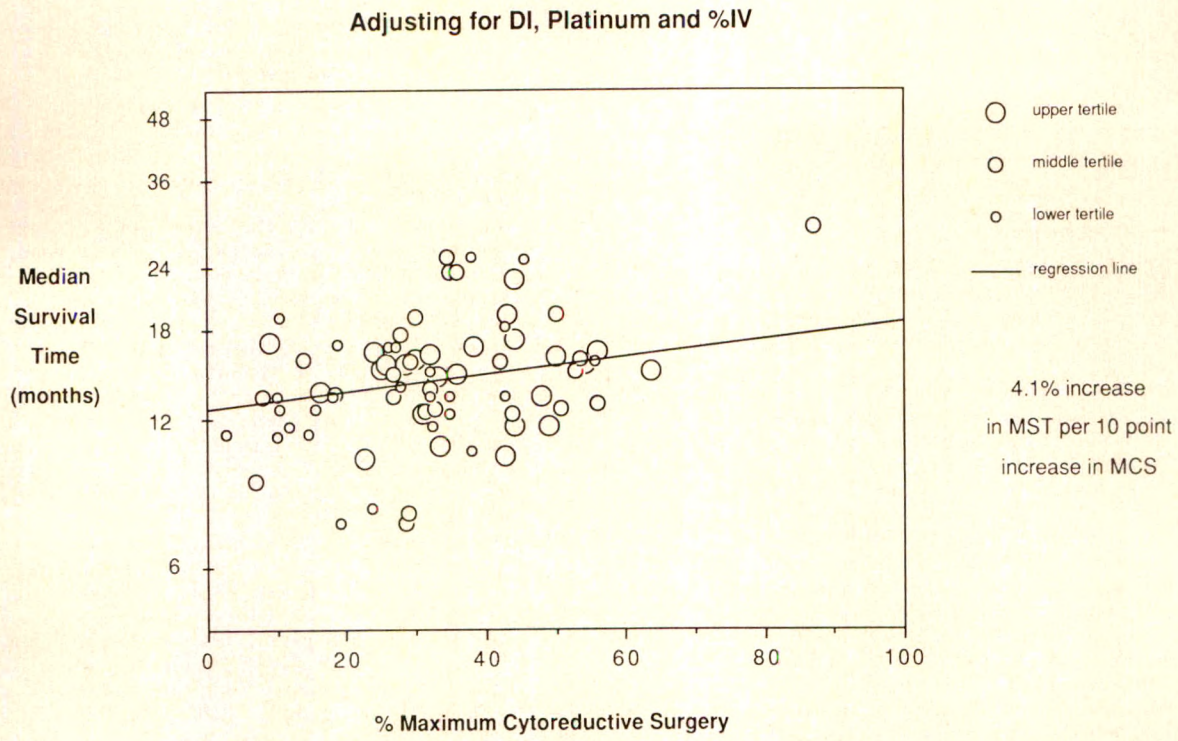

Fig. 2. Graph of log median survival time *(MST)* (months) versus percent maximum cytoreductive surgery *(MCS)* for 76 cohorts for which dose intensity could be calculated after adjustment for effects of dose intensity, percent stage IV, and platinum chemotherapy.

cytoreductive surgery is still relatively small, and this is probably more important than the existence or otherwise of formal statistical significance. Publication bias is unlikely to have affected the conclusions of this analysis, because the large majority of the studies included were investigating chemotherapy rather than surgery. Any publication bias that may exist would tend to exaggerate any beneficial effects of surgery.

The value of radical cytoreductive surgery in improving patient survival has been questioned by others. Hacker et al.[3] have shown that patients with metastatic disease >10 cm before surgery did poorly in spite of optimal cytoreduction, and Webb[24] found that patients in whom bowel resection was necessary to produce maximum cytoreductive surgery had a very poor prognosis. Patients requiring resection of the urinary tract also fare badly,[64] with a median survival time of 12 months, which is further reduced to 7 months if preoperative intravenous urography shows obstruction.

Several uncontrolled studies have shown that patients with minimal residual disease after surgery have a better survival and response to chemotherapy than those left with bulky residual disease.[1-3] However, it seems that using cytoreductive surgery to increase the proportion of such women in a population of patients with advanced ovarian cancer confers only a small survival advantage on the group as a whole. It seems likely that this is another example of the "Will Rogers phenomenon," in which reclassification of patients can improve the survival of the new subgroups without altering the survival of the whole population.[65]

Median survival is not the only measure of treatment benefit. This study could not address the effect of surgery on short-term survival and quality of life or on long-term survival. The symptoms of advanced ovarian cancer are relieved by excision of all large tumor masses. An improved quality of life after cytoreduction was seen in terms of returning to work, eating a normal diet, and enjoying life, compared with patients who had suboptimal surgery.[66] These women had less frequent hospital admissions, fewer procedures such as paracentesis, and fewer episodes of bowel obstruction. However, this was not a controlled study.

It is concluded that maximum cytoreduction surgery produces at best only a small improvement in median survival in advanced ovarian cancer. There may be other benefits such as relief of symptoms and improved quality of life. The use of bowel or urinary tract resection to debulk disease is more questionable because of the associated poor survival and higher morbidity. A large, controlled trial of surgery in advanced ovarian cancer is required to confirm or refute these conclu-

sions. However, there will be considerable practical and ethical difficulties in any such trial.

We thank the many colleagues who have helped by discussing this analysis or by providing invaluable information from their own studies.

Transabdominal chorionic villus sampling: A modified freehand ultrasonographically guided technique

Lyndon M. Hill, MD, and Steven A. Laifer, MD
Pittsburgh, Pennsylvania

A simple modification of the technique of transabdominal chorionic villus sampling is described. This technique uses a short piece of extension tubing between the needle hub and aspirating syringe. The advantages of this technique are discussed. (Am J Obstet Gynecol 1992;166:512.)

Key words: Chorionic villus sampling, ultrasonography

Transabdominal chorionic villus sampling is an effective method for prenatal diagnosis, allowing adequate sampling in >90% of cases.[1] In the typical two-person technique, an assistant performs the ultrasonographic examination. The primary operator inserts the biopsy needle into the placenta, connects a 20 ml syringe to the needle hub, and then aspirates during a slow, backward-and-forward movement of the needle tip.[2] However, the sudden aspiration that is required for tissue sampling may alter the position of the needle in the placenta. Furthermore, redirection of the needle during aspiration is cumbersome and does not readily permit fine needle placement. A modification of the transabdominal villus sampling technique allows the operator to concentrate on needle placement, while the assistant's primary responsibility is aspiration.

Method

Simultaneous ultrasonographic imaging is performed with a 3.5 MHz curvilinear transducer (General Electric model RT3200; General Electric, Milwaukee). A 15 cm rather than a 9 cm sampling needle provides the operator with sufficient needle length to obtain a villus sampling in nearly every patient.

Before the procedure is started, a 20 ml syringe containing 3 ml of transport medium is attached to a short piece of extension tubing (0.5 ml dead space) (Fig. 1).

Once the operator has inserted the needle into the placenta, the stylet is withdrawn and the distal end of the extension tubing is attached to the needle hub. Repeated rapid aspiration of the plunger is applied by an assistant to obtain a chorionic villus sample. The extension tubing removes the assistant from direct contact with the needle. The operator can therefore concentrate on the important tasks of scanning and needle localization. Continuous monitoring of the needle tip helps to avoid inadvertent amniotic membrane penetration.

The Diabetes in Early Pregnancy Study: Changes in cholesterol, triglycerides, body weight, and blood pressure

Charles M. Peterson, MD,[a] Lois Jovanovic-Peterson, MD,[a] James L. Mills, MD, MS,[b] Mary R. Conley, MA,[b] Robert H. Knopp, MD,[c] George F. Reed, PhD,[b] J.H. Aarons, MD,[d] Lewis B. Holmes, MD,[e] Zane Brown, MD,[e] Margot Van Allen, MD,[f] Ralph Schmeltz, MD,[d] Boyd E. Metzger, MD,[g] and The National Institute of Child Health and Human Development—The Diabetes in Early Pregnancy Study

Santa Barbara, California, Bethesda, Maryland, Seattle, Washington, Pittsburgh, Pennsylvania, Boston, Massachusetts, Toronto, Ontario, Canada, and Chicago, Illinois

This study examined changes in cholesterol, triglycerides, body weight, and blood pressure during pregnancy in 312 diabetic and 356 control women recruited within 21 days after conception. Cholesterol values rose in both groups but were significantly lower in diabetic women at each time point (166 vs 178 mg/dl at week 12, $p = 0.0004$). Triglyceride values also rose in both groups. Triglyceride levels did not differ between groups up to week 8 of gestation, but by weeks 10 to 12 they were significantly lower in diabetic women than in controls (75 vs 89 mg/dl at week 12, $p = 0.0004$). Although they were no heavier at entry, diabetic women gained significantly more weight between weeks 6 and 8 ($p < 0.001$), resulting in a mean difference between groups of 1 kg. Systolic blood pressure increased steadily and significantly in the diabetic but not the control women (115.8 ± 16.2 SD vs 109.3 ± 11.8 mm Hg, $p = 0.0006$ at term). Diastolic blood pressure was higher in diabetic women on entry (70.7 vs 67.3 mm Hg, $p = 0.0006$) and throughout gestation. Significant correlations were found in the diabetic group between maternal blood pressure and lipids and infant birth weight. These newly found differences in cholesterol and triglyceride levels, weight gain, and blood pressure between type I diabetic and control women during gestation may have long-term cardiovascular implications. (Am J Obstet Gynecol 1992;165:513-8.)

Key words: Pregnancy, diabetes, lipids, blood pressure, weight

Although the outlook has improved, the diabetic woman and her pregnancy remain at higher risk during gestation, and the mother has a fivefold risk for a cardiovascular event during her lifetime compared with the nondiabetic woman.[1-9] Because the National Institute of Child Health and Human Development—Diabetes in Early Pregnancy Study recruited control and diabetic women before or within 21 days after conception, it provided a unique opportunity to study maternal cholesterol, triglycerides, blood pressure, and weight change in diabetic and control women throughout gestation. The results reported here show marked differences for these variables between diabetic and control women.

Material and methods

The study included Cornell University, Harvard University, Northwestern University, The University of Pittsburgh, and The University of Washington. The National Institute of Child Health and Human Development was the data and coordinating center. The study design has been described in detail elsewhere.[10, 11] When the diagnosis of pregnancy was made during the week of the missed menses, diabetic subjects were hospitalized for 2 to 5 days for monitoring of metabolic control and performance of entry testing. Other than reinforcing the techniques of self–blood glucose monitoring, a standard approach to the management of diabetes was not imposed nor were fixed goals for glycemic control mandated. After discharge, diabetic subjects were monitored at weekly clinic visits from weeks 5 through 12 after the last menstrual period and monthly thereafter. Control subjects were entered and followed at biweekly intervals. Controls were screened for gestational diabetes at 26 weeks according to the criteria established by The Second International Gestational Diabetes Workshop.[12]

The thiobarbituric acid method was used for glycosylated hemoglobin analysis.[13] This method is not affected by fetal hemoglobin, which made it possible to perform all the tests on frozen, washed red blood cells

Table I. Maternal variables (mean ± SD)

	Diabetic (n = 312)	*Control (n = 356)*	*Significance*
Height (cm)	163.2 ± 7.3	164.1 ± 7.4	$p = 0.13$
Age (yr)	27.9 ± 4.0	29.6 ± 3.7	$p < 0.0001$

in a single laboratory. The method relies on the formation of a color when the Amadori rearrangement product (1-deoxy-fructosyl adduct) is heated in the presence of 0.3 oxalic acid to form 5-hydroxymethylfurfuraldehyde. Laboratory plasma glucose measurements were performed in each center by an enzymatic method.

Blood pressure was measured by standard protocol.[14] Plasma cholesterol and triglyceride levels were measured at each institution by standard methods.[15-17] Only two patients were on oral contraceptives in the month before conception.

Associations were measured by Fearson correlations, and comparisons were by t tests and paired t tests. Statistical significance was declared at the two-sided 0.05 level. Data were derived as repeated measures during the course of gestation, but a univariate analysis (by two-sided t test) at the examined weeks was made to better view weekly differences. Since there were at most six such comparisons, a Bonferroni criterion for statistical significance was applied to address the multiple comparisons problem presented by this approach. Thus, if a variable were measured at six different weeks of gestation, then a comparison at any week was judged significant at the 0.05 level if its p value did not exceed $0.05/6 = 0.0083$. In assessing whether a decreasing or increasing trend was present in the serial data, it was noted that observed changes were all monotone, so that an adequate test for trend was the paired t test of last measurement minus first measurement. Associations were measured by Pearson correlation coefficients.[10, 11, 18-21]

Results

The analysis was performed on 312 diabetic and 356 control patients who were delivered of live infants. Table I shows the comparison between diabetic and control groups for maternal height and age at entry into the study. The diabetic and control mothers were not different for height, but the control mothers were older. Table II documents the glycosylated hemoglobin by gestational week for each group. As would be expected, significant ($p = 0.0005$) differences were present between groups at each time point.

Table III shows the cholesterol values for the two groups of women during weeks 6 to 12 of gestation. The difference was most pronounced at 12 weeks with diabetic women having a mean cholesterol level of 165.7 ± 29.5 SD and control women having a mean level of 177.8 ± 36.0 mg/dl. The mean cholesterol level in the controls was significantly ($p < 0.01$) higher at each time point. Cholesterol and glycosylated hemoglobin values were not significantly correlated. A trend toward rising levels of cholesterol was seen in both diabetic and control populations and was significant when week 12 was compared with week 6 ($p = 0.0001$ for both groups). A significant correlation in the diabetic group was found between change in cholesterol levels between weeks 6 and 8 and infant birth weight ($p = 0.03$).

Table IV compares triglyceride levels in diabetic and control subjects. The two groups did not differ significantly at week 6 or 8. By week 12, the triglyceride levels of the diabetic women were significantly ($p = 0.0004$) lower than those seen in the controls (75.1 ± 36.2 SD vs 89.4 ± 44.4 mg/dl). Triglyceride levels rose significantly ($p < 0.001$) in both diabetic and control groups from week 6 to week 12. A correlation was not found between triglyceride levels and glycosylated hemoglobin values nor between triglyceride and cholesterol levels. A significant correlation in the diabetic group was found between change in triglyceride levels between weeks 6 to 10 and infant birth weight.

Table V documents the weights and Table VI the body mass index in the two groups of women throughout gestation. The groups did not differ significantly at initial hospitalization or at week 6. By week 8 the diabetic group was heavier and had a higher body mass index at each later comparison point until week 36. The change in weight and percent change began to be significantly higher in the diabetic group by week 8 ($p < 0.001$, week 8 vs week 6 between groups) and continued to be so at each later comparison point. The diabetic group reached term having gained 15 kg of body weight versus 14 kg for the control group. Tables VII through IX compare systolic, diastolic, and mean blood pressure in the two groups. The diabetic subjects had significantly higher systolic blood pressure at entry and from week 12 of gestation onward. At week 6, systolic blood pressure was not different between the groups (107.0 ± 11.4 SD for the control group and 108.7 ± 13.8 mm Hg for the diabetic group). Diastolic blood pressure was higher in the diabetic women at each time point, and after 20 weeks the diastolic pressure in the control women was about 5 mm Hg lower than in the diabetic group. For control women, systolic and diastolic blood pressures were lower at 6 weeks gestation than at entry and gradually rose to entry levels by delivery. In diabetic women, systolic blood pressure dropped significantly at 6 weeks but returned to entry levels by 12 weeks of gestation and continued to rise thereafter to term. Thus the change in blood pressure

from the initial hospitalization to the later points is also significantly greater for the diabetic subjects. Mean blood pressure was significantly higher for the diabetic group at every time point. Infant birth weight correlated with maternal blood pressure in the diabetic group at the initial hospitalization (p = 0.01) and at 28 weeks (p = 0.03).

Comment

One of the objectives of the Diabetes in Early Pregnancy Study was to examine the effect of diabetes on cholesterol, triglycerides, body weight, and blood pressure during pregnancy. Our data indicate that there are significant differences between diabetic and control women in maternal cholesterol, triglycerides, weight and blood pressure, variables that might contribute to risk for the pregnancy or subsequent maternal vascular disease. Although no relationship was found between the variables under consideration and fetal loss or congenital malformations, a relationship was found between maternal blood pressure and lipid changes and infant birth weight.

In nonpregnant subjects, previous studies have reported elevated cholesterol and triglyceride levels. The degree of elevation was positively correlated with glycosylated hemoglobin values.[21] It has been reported that nonpregnant women with type I diabetes mellitus with a mean fasting glucose of 208 mg/dl and an av-

erage age of 34 years had a 32 mg/dl greater total plasma triglyceride level and a 38 mg/dl greater total cholesterol level than nondiabetic women of similar age.[22]

Studies of pregnant diabetic patients have found either no change or an increase in triglyceride content or cholesterol over controls. The sutdy that included and separated type I subjects from controls, type II subjects, and those with gestational diabetes by trimester did not detect differences between normal and type I subjects.[23] From these observations in small numbers of nonpregnant and pregnant diabetic women, we would have expected normal or elevated triglyceride and cholesterol levels in pregnant diabetic women and a positive correlation with glycosylated hemoglobin. We found the reverse trend in pregnant subjects. In fact, significantly lower levels were found in type I diabetic women in our study for cholesterol and for triglycerides after 8 weeks gestation; neither triglyceride nor cholesterol levels correlated with glycosylated hemoglobin. The reasons for the different findings in our study may be in part due to the large numbers of subjects studied, which allowed for definition of relatively small differences and the different treatment programs used.

Hormonal differences might also contribute to the observed differences in lipid levels. Significant correlations between sex hormones in healthy young women and plasma lipoprotein levels have been documented, and diabetic women have been shown to have significant differences in hormonal profiles during gestation (which tend to normalize if glucose control is improved) compared with nondiabetic controls.[8, 24, 25]

Our results suggest that disposal of triglyceride and cholesterol may differ between diabetic and control women. Diabetic subjects from one of the participating centers were found to have a reduction in high-density lipoprotein, particularly high-density lipoprotein 3.[26] Changes in lipid transport to the fetus could provide a potent stimulus to macrosomia, a morbid complication of diabetic pregnancy frequently cited in the literature in "well controlled" patients.[27-30] The significant correlations found between changes in cholesterol levels and triglyceride levels between weeks 6 and 10 and infant birth weight are consistent with this hypothesis.

The reasons for increased weight gain in the pregnant diabetic women between weeks 6 and 8 remain to be defined. Since weight in the two groups was the same at the beginning of gestation, it would appear that the increased weight gain seen in insulin-dependent diabetic women is the result of the treatment program or pregnancy per se. Increased caloric intake or fluid retention could both play a role. The possibilities that diabetic women receive different caloric advice, or excess caloric intake is required to prevent symptomatic hypoglycemia early in gestation are also potential explanations for the excess weight gain, with implications for the current protocols used to treat pregnant diabetic women. The Diabetes Control and Complications Trial also documented an excessive weight gain in those type

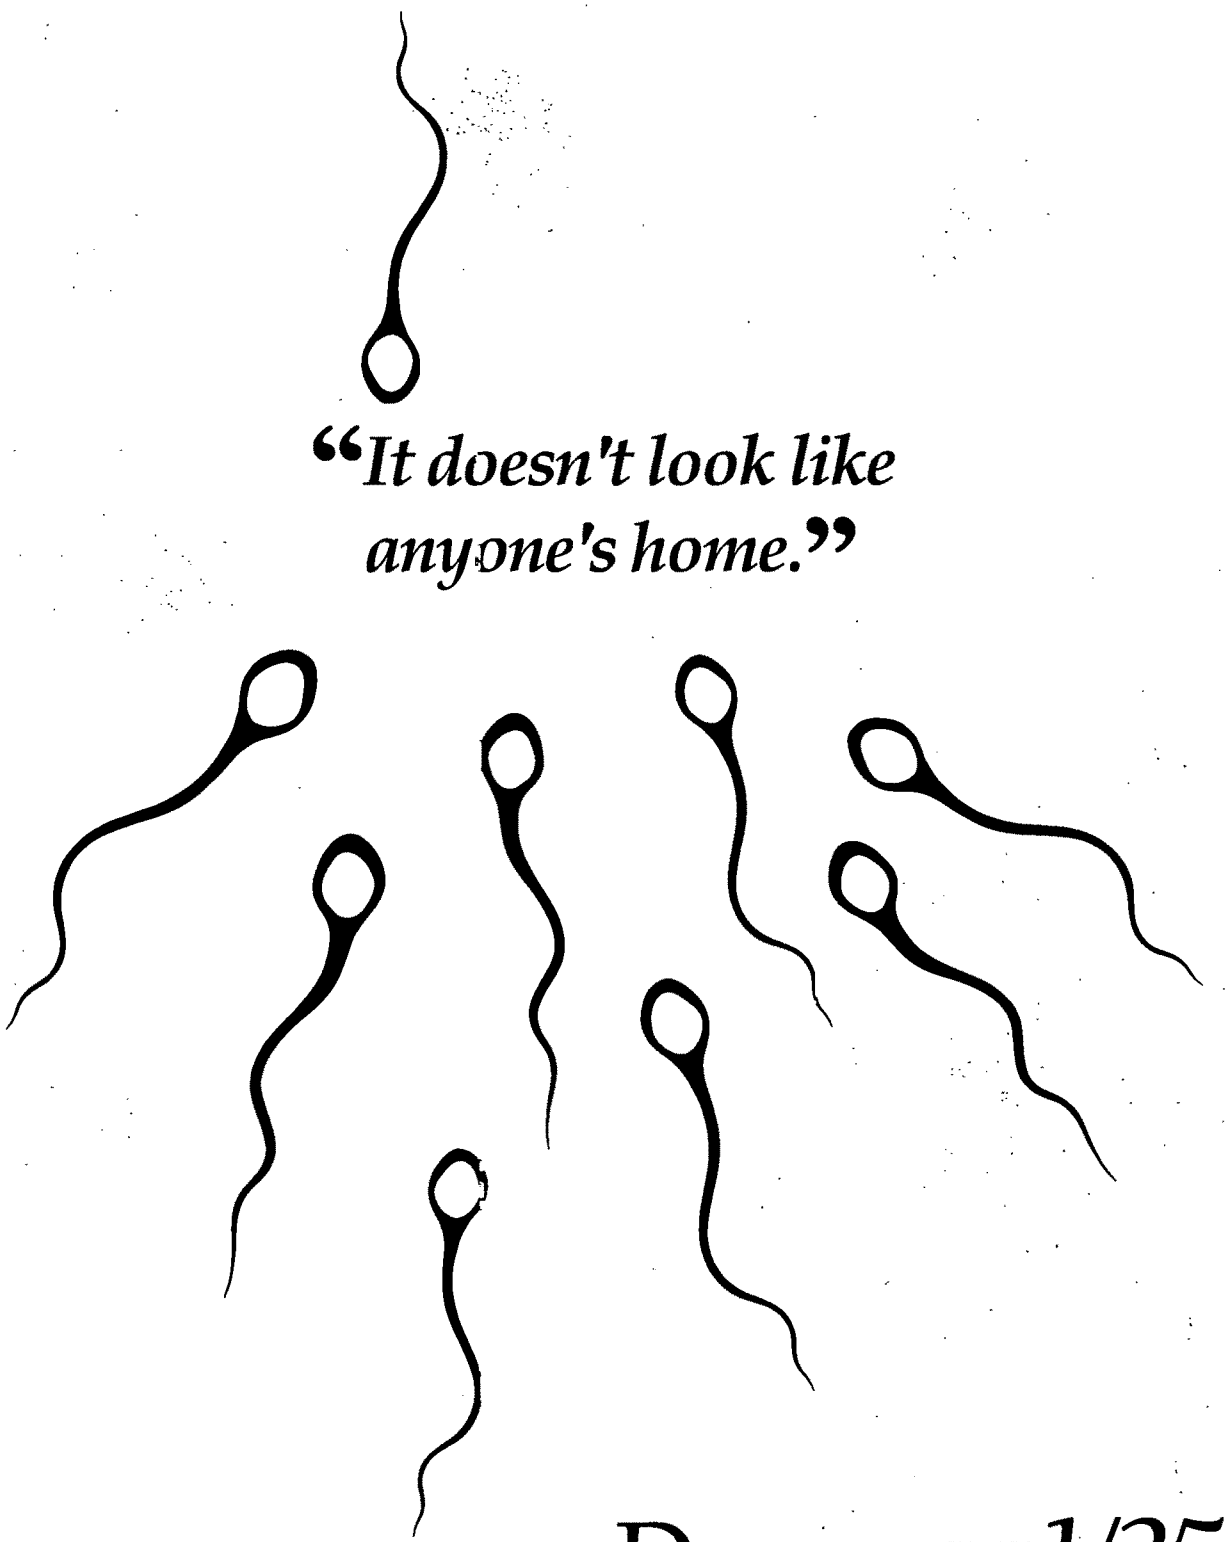
I diabetic women who were in the intensive management treatment group.[31] Protocols that use carefully titrated insulin dosage and food intake in type I diabetic women throughout gestation have not necessarily been associated with weight gain >12 kg.[8] The potentially adverse health implications of this documented weight gain for the mother warrant further study.

Insulin administration has been associated with salt and water retention.[32, 33] It can be assumed that all diabetic women in the study had high circulating insulin levels, because all received therapeutic insulin administered subcutaneously with a mean dose of 1.08 U/kg/24 hours at term. High circulating insulin levels have been associated not only with a higher risk for vascular disease but also with hypertension.[34]

Diabetic women were found to have higher diastolic and systolic pressures at every time point during gestation except 6 weeks, when systolic blood pressure was similar in the two groups. The present data not only point to the difference in blood pressure between the two groups but also provide impetus for the reevaluation of norms regarding blood pressure and the diagnosis of hypertension during gestation. For example, a blood pressure of 140/90 mm Hg was at 3 SDs above the normal mean at any observation point during gestation in the control group. The coefficient of variation for systolic blood pressure was extremely stable in the control group but increased throughout gestation in the diabetic women, indicating a subset of women whose pressor response to gestation is different from controls. Future research should consider whether such pressor changes are the result of vascular volume differences or increased insulin levels, whether they identify women at risk for vascular disease, and whether they warrant treatment.



The present study demonstrates the need for long-term studies to determine whether changes in lipids, weight, and blood pressure noted during pregnancy persist post partum and if pregnancy influences risk for cardiovascular events in type I diabetic women. Our findings emphasize the need for studies during pregnancy and thereafter to develop standards related to outcome criteria and norms for risk factors for vascular disease in this population. For example, reference values for lipoprotein lipids have been described for 36 weeks' gestation[35] but not earlier in pregnancy. Such data might allow the identification of women at risk for vascular disease at a time in their lives when therapeutic intervention is highly feasible.

We thank Lewis Kuller and Ronald LaPorte for review of the manuscript.

DEMULEN® 1/35

(ethynodiol diacetate 1 mg, ethinyl estradiol 35 mcg)

Where protection begins

The physician should become familiar with the prescribing information (labeling) for this product, which discusses reported risks, such as thromboembolic disorders (including strokes and heart attacks), risk of estrogen dose, and hepatic lesions, as well as the need to monitor patients for early symptoms of any diseases or medical conditions, so use can be discontinued when appropriate.

Please see adjoining page for a brief summary of prescribing information.

The OC innovator **SEARLE**

DEMULEN® 1/35 Where protection begins

(ethynodiol diacetate 1 mg, ethinyl estradiol 35 mcg)

BRIEF SUMMARY

Demulen® 1/35: Each white tablet contains ethynodiol diacetate 1 mg and ethinyl estradiol 35 mcg. Each blue tablet in Demulen 1/35-28 is a placebo containing inert ingredients. **Demulen® 1/50:** Each white tablet contains ethynodiol diacetate 1 mg and ethinyl estradiol 50 mcg. Each pink tablet in Demulen 1/50-28 is a placebo containing inert ingredients.

Indication and usage: For prevention of pregnancy. Pregnancy rate for products with ≥35 mcg ethinyl estradiol or ≥50 mcg mestranol is ≤1/100 woman-years. With ≤35 mcg ethinyl estradiol, rate is slightly higher; with progestogen-only oral contraceptives (OCs), rate is about 3. Precise comparisons cannot be made. Rates for other methods have been published. *Dose-related Thromboembolic Risk:* Studies showed positive association between OC estrogen dose and thromboembolic risk. It is in keeping with good therapeutics to minimize estrogen exposure. Prescribe product containing least amount of estrogen compatible with acceptable pregnancy rate and patient acceptance. Start new users on ≤50 mcg estrogen.

Contraindications: Thrombophlebitis, thromboembolic disorders, past history of deep vein thrombophlebitis or thromboembolic disorders; cerebrovascular disease, myocardial infarction or coronary artery disease, or past history of these; known or suspected breast carcinoma, estrogen-dependent neoplasia, or pregnancy; undiagnosed abnormal genital bleeding; past or present, benign or malignant liver tumors developing during use of estrogenic products.

Warnings:

Cigarette-smoking increases risk of serious cardiovascular side effects from OC use. Risk increases with age and heavy smoking (15 or more cigarettes/day) and is quite marked in women over 35. OC users should be strongly advised not to smoke. OCs are associated with increased risk of several serious conditions including venous and arterial thromboembolism, thrombotic and hemorrhagic stroke, myocardial infarction, visual disorders, hepatic tumors, gallbladder disease, hypertension, fetal abnormalities. Practitioners should be familiar with the available information relating to these and other risks.

1. *Thromboembolic disorders and other vascular problems:* Increased risk of thromboembolic and thrombotic disease associated with OCs is well established. A British study showed increased risk for fatal venous thromboembolism (TE). British and U.S. studies showed increased risk for nonfatal disease. U.S. studies showed increased risk for stroke. OC users were 2-11 times more likely to manifest these diseases without evident cause. In a study of idiopathic deep vein thrombosis and pulmonary embolism (PE), projected hospitalization rates for ages 16-40 were 47/year/100,000 users and 5 for nonusers. Overall excess mortality from PE or stroke was 1.3-3.4 deaths/year/100,000 users and increased with age. *Cerebrovascular Disorders:* In a study of stroke with and without predispositions, risk of hemorrhagic stroke was 2 times greater and thrombotic stroke 4.0-9.5 times greater in users. Mortality trends in 21 countries indicate that changes in cardiovascular mortality were associated with changes in OC prevalence. The Royal College of GPs (RCGP) reported on its prospective study: "A statistically significant higher rate of reporting of cerebrovascular accidents in Takers is evident, but the numbers are too small to justify an estimation of the degree of risk." A 1981 analysis showed a 4-fold increased mortality in users from circulatory diseases, mainly myocardial infarction (MI) and hemorrhagic stroke. Excess mortality was associated with age and smoking. A 1983 analysis showed elevated cerebrovascular disease, increasing with use to 8 yrs, including cerebral thrombosis or embolism and TIA. Peripheral arterial disease and MI were increased. Women over 30 had more arterial disease, being greatest in smokers. Arterial case-fatality was 2-3 times greater for users who smoked. Family Planning Assoc. (FPA) found significant association between OC use and stroke; increased risk for venous thrombosis and PE was 4-fold and statistically significant. Mortality from nonrheumatic heart disease was greater in ever-users. In the Walnut Creek Study, subarachnoid hemorrhage risk was associated with smoking, age, and OC use. *Myocardial Infarction:* Increased risk of MI associated with OCs was reported in Britain, as previously suspected. The morbidity study found the greater the number of risk factors for coronary artery disease (smoking, hypertension, hypercholesterolemia, obesity, diabetes, history of preeclamptic toxemia) the higher the risk, regardless of OC use. OCs were an additional risk factor. Excess rate of fatal MI was 3.5/year/100,000 users aged 30-39 and 20 for ages 40-44. (These are based on British statistics with acute MI death rates 2-3 times less than the U.S. Similar estimates for the U.S. are 25.7 for users aged 30-39 with predispositions vs 1.5 without; for ages 40-44, 86.2 vs 5.1.) Excess hospitalization rate for nonfatal MI in Britain was 3.5/year/100,000 users aged 30-39 and 47 for ages 40-44. Smoking is a major predisposing condition to MI. In terms of relative risk, nonsmoking OC users are twice as likely to have fatal MI as nonsmoking nonusers. Smoking users have a 5-fold greater risk than nonsmoking users, but a 10-12-fold greater risk than nonsmoking nonusers. Amount of smoking is an important factor. In determining importance of these risks, give serious consideration to rates in table below. Importance of other predispositions cited above in determining relative and absolute risks has not been quantified; it is likely the same synergism exists, but perhaps to a lesser extent. U.S. studies similarly relate MI, OCs, smoking, and age.

Estimated Mortality Rate from Myocardial Infarction per 100,000 Women-Year

	Aged 30-39:	*Users*	*Nonusers*	*Aged 40-44:*	*Users*	*Nonusers*
All smokers		10.2	2.6		62.0	15.9
≥15 cigarettes daily		13.0	5.1		78.7	31.3
<15 cigarettes daily		4.7	0.9		28.6	5.7
Nonsmokers		1.8	1.2		10.7	7.4
Smokers and nonsmokers		5.4	1.9		32.8	11.7

Risk of Dose: Reports of TE after use of OCs with ≥50 mcg estrogen received by drug safety committees in Britain, Sweden, and Denmark were compared with distribution expected from market research sales estimates. A positive correlation was found between estrogen dose and reporting of TE, including coronary thrombosis, in excess of that predicted by sales. OCs with ≥100 mcg estrogen were associated with higher TE risk than those with 50-80 mcg. Estrogen quantity may not be the sole factor; influence of progestogens was not considered, which may be responsible for certain discrepancies in the data. No significant differences were noted between OCs containing same estrogen dose nor between ethinyl estradiol and mestranol. In Britain certain TE conditions were associated with progestogen or estrogen dose. In Sweden reports of TE decreased when higher estrogen doses were no longer prescribed. Studies on TE risk with progestogen-only OCs have not been done. Cases have been reported for these; they are not presumed free of risk. In a U.S. case-controlled study, relative risk of OC use 1 month before hospitalization for various types of TE was calculated. If relative estrogenic potency and possible influence of different progestogens are ignored, OCs may be divided into those with <100 mcg and those with ≥100 mcg estrogen. For all cases combined, larger doses were associated with only slightly higher risk; for idiopathic cases risk was doubled with larger doses, but confidence limits overlapped and differences were not significant. Apparently there was less increased risk for cases with predispositions. In FPA study no nonhemorrhagic strokes occurred with <50 mcg estrogen, vs 13 with higher doses. Latter group also had more venous TE. TE risk in users and nonusers increases with age. OCs have been considered an independent risk factor. Decreased HDL, which relates to increased myocardial ischemia, occurs with high progestational activity. Consider amount of both steroids in choosing OC. *Persistence of Risk* after OC discontinuation was reported for circulatory disease, nonrheumatic heart disease, and cerebrovascular disease, including subarachnoid hemorrhage, cerebral thrombosis, and TIA. *Excess Mortality from Circulatory Diseases:* A U.K. prospective study estimated annual mortality from circulatory diseases for OC users and nonusers by age, smoking, and duration of use. Excess mortality was 23/100,000 users (2 and 10 for ages 25-34, 15 and 48 for ages 35-44, 41 and 179 for ages >44, for nonsmokers and smokers, respectively). Risk was significant only for smokers over 34. Most deaths were due to subarachnoid hemorrhage or ischemic heart disease. Risk for ever-users rose with parity. One study estimated risk of death with various contraceptive methods, each estimate including risk of method (eg, TE for OCs) plus risk due to pregnancy or abortion in cases of method failure. This latter risk varies with effectiveness. It concluded mortality with all methods is low and below that of childbirth, except for OC users over 40 who smoke. Heavy smokers have double the risk of smokers, light smokers about half. Mortality with OC use in nonsmokers over 40 is higher than with any other method in that age group. Lowest mortality is with condom or diaphragm backed up by early abortion. Risk of TE and thrombotic disease with OCs increases with age after 30 and, for MI, is further increased by hypertension, hypercholesterolemia, obesity, diabetes, history of preeclamptic toxemia, and especially cigarette smoking. Based on current data, the chart gives gross estimates of risk of death from circulatory disorders associated with OCs:

Risk is: A—very high; B—high; C—moderate; D—low.	Age: <30	30-39	≥40
Heavy smokers (≥15/day)	C	B	A
Light smokers (<15/day)	D	C	B
Nonsmokers, no predispositions	D	C,D	C
Nonsmokers, with predispositions	C	C,B	B,A

Be alert to earliest manifestations of TE disorders (eg, thrombophlebitis, PE, cerebrovascular insufficiency, coronary artery disease, MI, retinal thrombosis, mesenteric thrombosis). Should any be suspected, discontinue OCs immediately. A 4-7-fold increased risk of postsurgery TE was reported in users; if feasible discontinue OCs at least 4 weeks before surgery or in prolonged immobilization. Before resuming OCs, weigh risks of postsurgery TE complications against contraceptive needs. RCGP reported higher incidence of superficial and deep vein thrombosis in users, the former correlated with progestogen dose. Varicose veins have little effect on development of deep vein thrombosis. 2. *Ocular lesions:* Neuro-ocular lesions such as optic neuritis or retinal thrombosis have been associated with OCs. Discontinue if there is unexplained, gradual or sudden, partial or complete loss of vision; proptosis or diplopia; papilledema; or evidence of retinal vascular lesions. Institute diagnostic and therapeutic measures. 3. *Carcinoma:* Long-term estrogen in certain animals increases carcinomas and/or nonmalignant neoplasms, such as those of breast, uterus, cervix, vagina, ovary, liver, pituitary. Some synthetic progestogens, none currently in OCs, increase incidence of benign and malignant mammary nodules in dogs. Estrogens increase risk of human endometrial carcinoma. In case-controlled studies, increased risk (2.2-13.9 times) associated endometrial carcinoma with prolonged estrogen for menopausal symptoms. Risk was independent of other known risk factors and depended on duration of use and dose. This is supported by increased endometrial cancer incidence since 1969 in areas with cancer-reporting systems, which may be related to expanding estrogen use. There is no evidence that natural estrogens are more or less hazardous than synthetics. Of the first 30 cases of endometrial carcinoma in OC users under 40, those without predispositions occurred nearly always with no-longer-marketed sequential OCs. No statistical association is reported suggesting increased endo cancer with combination or progestogen-only OCs. Studies show no increased breast cancer with OCs or estrogens. H greater risk was noted in OC users with benign breast disease or long-term (2-4 years) use. One study found greater breast cancer with >4 years OC use prior to first full-term pregnancy. Risk of breast cancer with menopausal estroge and further increased with duration of follow-up. OCs or estrogen were related to breast cancer in connection with ot factors and in various subgroups. Decrease in benign breast tumors in OC users is well known. Some studies su increased risk of cervical dysplasia, CIN, erosion, and carcinoma in long-term users. Cervical microglandular hyperpl bean reported. In summary, there is no consistent evidence from human studies of increased cancer risk with OCs surveillance is, however, essential. In undiagnosed persistent or recurrent abnormal vaginal bleeding, consider nonfu causes and take diagnostic measures to rule out malignancy. Carefully monitor users with strong family history o cancer or with breast nodules, fibrocystic disease, recurrent cystic mastitis, abnormal mammograms, or cervical dy 4. *Hepatic adenomas, etc,* have been associated with OCs. In 1 study OC formulations with high "hormonal potenc associated with higher risk, as was age over 30. Though benign, these lesions may rupture and cause fatal hemoperi in short- or long-term users. Two studies related risk to duration of use, being much greater after ≥4 years. Long-t users have an estimated adenoma incidence of 3-4/year/100,000. Consider such lesions in users with abdomin tenderness, mass, or shock. About 25% present with abdominal masses, up to half with acute hemoperitoneum. Ra and lab studies may not be helpful; liver scans may show local defect. Hepatic arteriography or CAT may be Hepatocellular carcinoma risk is increased 7-20 times in users for 8 or more years. Bile duct cancer may occur with 5. *Use in or immediately preceding pregnancy, birth defects, malignancy in offspring:* Estrogens or progestogens duri pregnancy may seriously damage offspring. Females exposed in utero to DES and other nonsteroidal estrogens ma increased risk of vaginal or cervical cancer. Though OCs may not enhance this risk, monitor such patients carefully. Fr 90% of DES-exposed women develop benign vaginal or cervical adenosis, which could be premalignant. DES-e daughters have more unfavorable pregnancy outcomes. Males so exposed may develop urogenital and sperm defects estrogens may mimic DES. Reports relate fetal exposure to female sex hormones and congenital anomalies, eg, VACT vertebral, anal, cardiac, tracheoesophageal, renal, and limb defects. There appears preferential expression by males was a 4.7-fold increased risk of limb-reduction defects in infants exposed in utero to sex hormones (OCs, hormonal wit pregnancy tests, or treatment for threatened abortion). Some exposures were very short, being only a few days. Cardio defects in children exposed to female hormones, including OCs, during early pregnancy occurred in 18.2/1,000 compared to 7.8 for those unexposed (P<.05). Female hormone exposure in utero was associated with testicular and cancer. More twinning was reported in conceptions shortly after OC discontinuance. Female sex hormones were u threatened or habitual abortion, but there is considerable evidence estrogens are ineffective and no evidence proge are effective. Triploidy and possibly other polyploidy may be increased in abortuses from women becoming pregna post-OC. These almost always abort spontaneously. It is unknown if spontaneous abortion is increased soon after s OCs. Increased chromosome aberrations have been reported. Safety of OCs in pregnancy has not been demonstrate out pregnancy in using OCs and always consider it if withdrawal bleeding does not occur. If 2 consecutive periods are rule out pregnancy before continuing. If user deviates from regimen, consider pregnancy at first missed period and v OCs. If pregnancy is confirmed, stop OC and apprise patient of potential fetal risks and discuss continuation of pre Users discontinuing for pregnancy should use alternative contraception for 3 months before attempting to conceive, this is not based on precise information. Do not use progestogen-only or progestogen-estrogen drugs as pregnanc 6. *Gallbladder disease* risk, surgically confirmed, appeared after 2 years' use and doubled after 4-5 years in 1 s appeared in 6-12 months' use in another. Bile duct cancer has been reported. 7. *Carbohydrate and lipid metabolism:* De glucose tolerance occurs in a significant number of users; carefully observe diabetic and prediabetic patients. Triglyc total phospholipids, and lipoproteins may increase. 8. *Elevated blood pressure* (BP) occurs in some users in a few and degree may relate to progestogen dose. Hypertension prevalence in users is not higher in the first year, but in with longer exposure; in the 5th year it is 2½–3 times the first year. Age is strongly correlated with hypertension in Those with history of elevated BP (hypertension), preexisting renal disease, history of toxemia or elevated BP in pre familial tendency to hypertension or its consequences, or history of excessive weight gain or fluid retention during me cycles may be more likely to develop elevated BP on OCs and should be monitored closely. Even though elevated BP in "normal" range, do not ignore implications. Follow closely, particularly those with other risk factors for cardiov disease or stroke. High BP may or may not persist after stopping OCs. 9. *Headache:* Onset or exacerbation of migr development of headache of a new pattern that is recurrent, persistent, or severe requires stopping OCs and evaluating 10. *Bleeding irregularities:* Breakthrough bleeding (BTB), spotting, and amenorrhea are frequent reasons for discontinu BTB, as in all cases of irregular bleeding, consider nonfunctional causes. In undiagnosed persistent or recurrent bleedi out pregnancy or malignancy. If pathology is excluded, time or change to another product may suffice. Change to a estrogen OC only when necessary as this may increase thromboembolic risk. Those with history of oligomenor secondary amenorrhea or without established regular cycles may be anovulatory or amenorrheic after discontinuing, with such problems should be so informed and other methods encouraged. Post-use anovulation, possibly prolonge occur in women without previous irregularities. Higher incidence of galactorrhea and of pituitary tumors has been ass with postpill amenorrhea. One study reported 16-fold increased prevalence of pituitary prolactin-secreting tumors in p with postpill amenorrhea when galactorrhea was present. 11. *Ectopics:* In failures with combination OCs, the ratio of to intrauterine pregnancies is no higher than in nonusers. 12. *Breast feeding:* OCs may decrease quantity and quality A small fraction of OC steroids appears in milk. Effects if any on child are unknown. If feasible defer OCs until after w 13. *Infertility* may occur after discontinuing OCs. While impairment diminishes with time, there is still an appreciable dif in nulliparas aged 25-29 after 30 months; difference is negligible after 48 months. In nullips aged 30-34 impairment to 72 months and is more severe for 2-year users. In paras aged 25-34, difference is negligible after 30 months. **Precaution** Conduct complete history and physical prior to OC use and annually thereafter. Include breasts, abdomen, and pelvi BP, Pap, and lab tests. Preexisting uterine leiomyomata may enlarge. Mental depression may occur; with positive observe carefully and discontinue if serious recurrence. Fluid retention may occur; prescribe cautiously and monitor c in convulsive disorders, migraine, asthma, or cardiac, hepatic, or renal dysfunction. History of jaundice in pregnancy in risk of recurrence on OCs: observe carefully and discontinue if it occurs. Cholestatic jaundice occurred after troleandomycin use. OC/cyclosporine combination may be hepatotoxic. Steroids may be poorly metabolized in liver dysf and should be given cautiously. Tryptophan metabolism may be disturbed and result in pyridoxine deficiency; megalo anemia has been reported. Serum folate may be depressed and may be exacerbated in post-OC pregnancy. Advise path of OC use when submitting specimens. Endocrine and liver function tests may be altered; repeat abnormal tests after st for 2 months. These have been observed: increased BSP retention and other abnormalities in liver function tests; inc prothrombin and coagulation factors VII, VIII, IX, X; decreased antithrombin III, increased platelet aggregability; inc thyroid-binding globulin leading to increased circulating total thyroid hormone (PBI, T^4); decreased T^3 uptake, unalter T^4, decreased pregnanediol excretion; reduced metyrapone response; increased blood transcortin, corticosteroid, trigly phospholipid, reduced serum folate; impaired glucose tolerance; altered plasma trace minerals. Influence of prolonged on pituitary, ovarian, adrenal, hepatic, or uterine function, or on immune response not established. OCs may mask o climacteric. Cervical chlamydial and gonorrheal prevalence is increased; do not assume OC protects against chlamydi HIV seropositivity was associated with OC use. *Information for patients.* See patient labeling. *Drug interactions.* OC effecti may be decreased and more BTB occur with rifampin, isoniazid, ampicillin, neomycin, penicillin V, tetracycline, chloramph sulfonamides, nitrofurantoin, griseofulvin, barbiturates, phenytoin, carbamazepine, primidone, phenylbutazone, anal tranquilizers, antimigraines. OCs may alter effectiveness of oral anticoagulants, anticonvulsants, tranquilizers, t antidepressants, antihypertensives, theophylline, caffeine, vitamins, hypoglycemics, clofibrate, glucocorticoids, acetamin **Adverse reactions:** Increased risk of the following serious adverse reactions has been associated with OCs: thrombop and thrombosis; pulmonary embolism; arterial thromboembolism; Raynaud's disease, myocardial infarction; c thrombosis; cerebral thrombosis; cerebral hemorrhage; hypertension; gallbladder disease; Budd-Chiari syndrome; adenomas and other hepatic lesions, with or without intra-abdominal bleeding, liver cancer, congenital abnormalities. T evidence of association between the following and OCs, though confirmatory studies have not been done; mes thrombosis; neuro-ocular lesions, eg, retinal thrombosis and optic neuritis. The following are believed drug related: vomiting, gastrointestinal symptoms, BTB, spotting, change in menstrual flow, dysmenorrhea, amenorrhea during an use, infertility post-OC, edema, chloasma or melasma, which may persist post-OC, breast changes (tenderness, enlarg secretion), weight changes, change in cervical erosion and secretion, endocervical hyperplasia, lactation decrease, chol jaundice, migraine, enlarged uterine leiomyomata, allergic rash, mental depression, reduced carbohydrate tolerance, cardiopathy, change in corneal curvature (steepening), intolerance to contact lenses. Association not confirmed or refut premenstrual-like syndrome, cataracts, libido changes, chorea, appetite changes, cystitis-like syndrome, headache, pares nervousness, dizziness, auditory disturbances, rhinitis, fatigue, backache, hirsutism, scalp hair loss, erythema multifo nodosum, hemorrhagic eruption, herpes gestationis, hidradenitis suppurativa, hemolytic uremia, malignant hyperte impaired renal function, acute renal failure, sometimes irreversible, itching, vaginitis, porphyria, PVCs, abnormal pulmonary hypertension, TTP, anemia, pancreatitis, hepatitis, colitis, Crohn's disease, gingivitis, dry socket, lupus erythema rheumatoid arthritis, pituitary tumors (eg, adenoma) with amenorrhea and/or galactorrhea after use, malignant mela endometrial, cervical, breast, and bile duct carcinoma. **Acute overdosage:** Serious ill effects have not been reporte large acute doses of OCs in young children. Nausea and withdrawal bleeding might occur. **Important note: Co prescribing information should be consulted prior to use and is available on request.**

Pelvic inflammatory disease: Findings during inpatient treatment of clinically severe, laparoscopy-documented disease

Charles H. Livengood III, MD, Gale B. Hill, PhD, and W. Allen Addison, MD
Durham, North Carolina

OBJECTIVES: We evaluated the relationship between clinically severe pelvic inflammatory disease and laparoscopic diagnosis and grading, comparative treatment with clindamycin plus cefamandole or doxycycline, and a management protocol for inpatient pelvic inflammatory disease treatment.
STUDY DESIGN: Thirty-three patients who met our clinical criteria for severe pelvic inflammatory disease underwent diagnostic laparoscopy. Pelvic inflammatory disease patients were randomized to double-blind treatment with clindamycin plus cefamandole or doxycycline within our management protocol; postdischarge oral antibiotics were omitted.
RESULTS: Laparoscopy confirmed pelvic inflammatory disease in 23 (70%) patients; 10 (44%) had mild pelvic inflammatory disease by laparoscopic grading. Laparoscopic grade alone predicted necessary duration of therapy to response: mild pelvic inflammatory disease, 2.3 ± 0.5 days; moderate pelvic inflammatory disease, 2.7 ± 1.5 days; and severe pelvic inflammatory disease, 3.9 ± 1.5 days ($p < 0.05$). Using the management plan presented, response rates for both antibiotic regimens were 100%.
CONCLUSIONS: Clinical diagnosis and grading of severe pelvic inflammatory disease has poor specificity. Laparoscopic grading of severity of pelvic inflammatory disease seems accurate. Both clindamycin plus cefamandole and clindamycin plus doxycycline are equally effective regimens for treatment of pelvic inflammatory disease and did not require supplementation after discharge. Our management plan is objective and practical; daily bimanual examination is the most sensitive indicator of persistent disease.
(Am J Obstet Gynecol 1992;166:519-24.)

Key words: Pelvic inflammatory disease, laparoscopy, clindamycin

Laparoscopic examination of patients having pelvic inflammatory disease of unclassified severity by clinical diagnosis has shown the specificity of clinical diagnosis to be ≤65%.[1, 2] Clinically severe pelvic inflammatory disease, generally treated with inpatient therapy, is a diagnosis of uncertain specificity. In 1986 Washington et al.[3] estimated the direct costs of outpatient and inpatient treatment for pelvic inflammatory disease to be $150 and $2865, respectively, and patients with clinically more severe disease are in greater jeopardy from misdiagnosis. Thus for both economic and medical reasons a better understanding of the accuracy of a clinical diagnosis of severe pelvic inflammatory disease is important. Further, a well-accepted laparoscopic grading system[4, 5] for pelvic inflammatory disease is in place, but neither the scope of its usefulness in managing clinical disease nor its correlation with clinical findings has been fully explored.

Indications for inpatient treatment of pelvic inflammatory disease remain subjective and variable. Current recommendations for hospitalization from the Centers for Disease Control[6] are based on compliance issues and clinical severity of disease, but the latter is undefined. Further, after hospitalization and initiation of a parenteral antibiotic regimen, those circumstances that confirm that adequate therapy has been given and those indicating therapeutic failure with the regimen in use are not well understood. Although many antibiotic regimens have been used with success in the parenteral treatment of pelvic inflammatory disease, optimal therapy can be identified only with continued study of currently available agents.

We undertook this study to examine the accuracy of routine clinical diagnosis of pelvic inflammatory disease and our own criteria for severe pelvic inflammatory disease requiring inpatient therapy, to evaluate the clinical usefulness of the accepted laparoscopic grading system and our management plan (outcome classification system) defining therapeutic success and failure, and to study the relative efficacy and safety of clindamycin with either cefamandole or doxycycline in the treatment of clinically severe pelvic inflammatory disease.

Material and methods

Women seen in the outpatient and emergency facilities of Duke University Medical Center and assigned a clinical diagnosis of severe pelvic inflammatory disease, for which we uniformly use inpatient therapy, by an attending physician in the Department of Obstetrics and Gynecology were considered for this study. In that

Table I. Therapeutic outcome classifications for patients hospitalized for pelvic inflammatory disease

Response: Requires at least five of the following
1. All symptom parameters (see text) = none or mild
2. Cervical motion and adnexal tenderness = none or mild
3. Abdominal tenderness and distention = none or mild
4. Temperature ≤37.8° C (oral) for ≥24 hr
5. White blood cell count between 4000/mm³ and 10,000/mm³ or >30% decrease if >10,000/mm³ on admission
6. Pelvic mass did not develop and if initially present did not increase in size on examination

Failure:

Progression of disease: After 24 hours of therapy, worsening of at least four of the parameters above; after 48 hours, at least three; onset of septic shock at any time

Inadequate improvement: After 96 hours of therapy, failure to improve in at least two of the parameters above

Late failure: Response criteria not met by 14 days of therapy or relapse of disease within 10 days of discontinuation of therapy (relapse defined as failure to continue to satisfy criteria for response above)

Side effect failure: Onset of any drug-related condition significantly threatening the comfort or health of the patient

pelvic inflammatory disease were required. However, to qualify for severe pelvic inflammatory disease and entry into this study, one or more of the following criteria were required: significant peritonitis defined by low abdominal rebound tenderness extending to the upper abdomen, vomiting, or paralytic ileus by examination; temperature ≥39.0° C orally; peripheral white blood cell count >20,000/mm³ or <4,000/mm³; postural hypotension; adnexal fixation or mass on examination; or persistence or progression of disease by objective criteria after ≥72 hours of outpatient antibiotic therapy. Those excluded from study were as follows: (1) patients who were allergic to clindamycin, doxycycline, or cephalosporins; (2) those who were pregnant or breast-feeding; (3) patients in septic shock; (4) those requiring other antibiotic therapy; (5) those having severe intercurrent medical disease; (6) those having pregnancy-related pelvic infection; (7) those previously entered in this study; or (8) those <12 years old. Written informed consent approved by the institutional review board was obtained from each patient before participation.

A detailed history, examination, and laboratory data were obtained by one investigator (C.H.L.), who also participated in all laparoscopy procedures and examinations during therapy. Patients were taken to the operating room, and a laparoscopic diagnosis was determined while they were under general anesthesia. Patients without erythema, edema, or grossly purulent exudate from the oviducts were categorized as not having pelvic inflammatory disease. Patients confirmed to have pelvic inflammatory disease were classified as having mild disease (any erythema or edema of freely movable oviducts without purulent exudate), moderate disease (significant erythema or edema of oviducts with any tubal fixation, patency uncertain), or severe disease (presence of an inflammatory mass).[4,5] While in surgery all patients had endocervical specimens taken for cultures for *Neisseria gonorrhoeae* and *Chlamydia trachomatis*. Patients with a laparoscopic diagnosis of pelvic inflammatory disease had oviduct specimens obtained by either endotubal swabbing at the fimbria or needle aspirate as available; these were cultured for *N. gonorrhoeae, C. trachomatis*, genital mycoplasmas, and other aerobic and anaerobic bacteria with special media and glove box techniques we have previously detailed.[7,8]

Patients with pelvic inflammatory disease were then randomized postoperatively to intravenous antibiotic therapy consisting of clindamycin, 600 mg every 6 hours, and either cefamandole, 2 gm every 6 hours, or doxycycline, 100 mg, plus 10 ml 4% sodium bicarbonate alternating with placebo (5% dextrose in water) every 6 hours to achieve double blinding.

At the time of study entry and at 24-hour intervals after initiation of antibiotic therapy, the following signs were assessed and graded as 0 (none), 1 (mild), 2 (moderate), or 3 (severe): direct and rebound abdominal tenderness, abdominal distention, cervical motion tenderness, left and right adnexal tenderness, and left and right adnexal enlargement. Symptoms were graded on the same scale: pain, anorexia, malaise, nausea or vomiting, and constipation or diarrhea. Thus at each assessment a total sign score (0 to 24), total symptom score (0 to 15), peak oral temperature during the preceding 24 hours, and the peripheral white blood cell count for that day were recorded. Outcome classifications were based on these data, as shown in Table I. Protocol antibiotic therapy was continued for 48 hours after declaration of response and for a minimum of 5 days (20 doses), after which patients were discharged without supplemental oral antibiotic treatment. They were given instructions to report any symptoms suggestive of relapsing disease, cards requesting notification of the investigators if they were seen by another physician for relapsing disease, a return appointment in 1 month, and instructions for presumptive treatment of all sexual partners. Patients were contacted by telephone

Table II. Selected characteristics of patients given a clinical diagnosis of clinically severe pelvic inflammatory disease, compared by laparoscopic diagnosis; examination, and laboratory data*

Variable	*Pelvic inflammatory disease absent (n = 10)*	*Pelvic inflammatory disease present (n = 23)*	*Significance*
Examination findings at presentation			
Grossly purulent vaginal discharge	6 (60%)	14 (61%)	NS
Oral temperature ≥38.0° C	2 (20%)	11 (43%)	NS
Total sign score (mean)	11.3 ± 4.9	15.9 ± 2.4	$p < 0.05$
Pelvic mass by examination	3 (30%)	7 (30%)	NS
Abdominal tenderness = severe	7 (70%)	22 (96%)	$p < 0.05$
Adnexal tenderness = severe	9 (90%)	23 (100%)	NS
Laboratory data at presentation			
White blood cell count ≥10,000/mm³	6 (60%)	14 (61%)	NS
Erythrocyte sedimentation rate >15 mm/hr	3/6 (50%)	15/18 (83%)	NS
Band cells (%)	1.8 ± 2.3	3.3 ± 4.9	NS

NS, Not significant.

*Data are given as frequencies with percents for the group or as mean values ± SD; different denominators resulting from missing data are indicated for the variables.

or personally 10 days after discharge for a status check.

Evaluability of treatment efficacy required that all protocol procedures and conditions were satisfied and that no other antibacterial therapy was given during the 10 days after completion of protocol therapy. Statistical tests used were the two-tailed *t* test, Mantel-Haenszel χ^2, and analysis of variance.

Results

Of the 33 patients given a clinical diagnosis of severe pelvic inflammatory disease by our criteria, laparoscopy confirmed the presence of pelvic inflammatory disease in 23 (70%). Laparoscopic grade of disease among these 23 was mild in 10 (44%), moderate in 6 (26%), and severe in 7 (30%). Among the other 10 patients, the final diagnoses were viral enteritis (3 patients), ovulation (2 patients), pelvic adhesive disease (1 patient), degenerating uterine myoma (1 patient), endometriosis externa (1 patient), benign cystic teratoma of the ovary with rupture (1 patient), and ectopic pregnancy (1 patient). Epidemiologic data are as follows for patients with pelvic inflammatory disease by laparoscopy: age 23.4 ± 5.2 years; previous pelvic inflammatory disease in 10 patients (43%); history of any sexually transmitted disease in 17 (74%); multiple sex partners in the previous year in 12 (52%); sex partner treated for sexually transmitted disease in the previous month in 2 (9%); genital symptoms in a current sex partner in 2 (9%); history of intrauterine contraceptive device use in 6 (26%); oral, intrauterine contraceptive device, and no contraception in 6 (26%), 1 (4%), and 14 (61%), respectively; tubal sterilization in 2 (9%); and history of infertility and ectopic pregnancy in 11 (48%) and 1 (4%), respectively. We found no difference among patients without pelvic inflammatory disease for any of these parameters. Evaluation of symptoms of the current illness for those with pelvic inflammatory disease revealed a longest duration of any symptom of 6.3 ± 6.0 days, any bowel symptom in 19 (83%), any urinary symptom in 14 (61%), abnormal vaginal discharge in 9 (39%), abnormal uterine bleeding in 9 (39%), lateralization of pelvic pain in 12 (52%), fever in 14 (61%), chills in 17 (74%), onset during the follicular phase in 14 of 20 (70%), and total mean symptom score of 9.0 ± 2.9. Although there was no difference between the pelvic inflammatory disease and non–pelvic inflammatory disease groups for any of these symptoms, the frequencies of pain involving the upper abdomen were 11 (48%) and 1 (10%), respectively ($p < 0.05$). Table II shows a comparison among patients with and without pelvic inflammatory disease by laparoscopy of examination and laboratory data commonly used in the clinical diagnosis of pelvic inflammatory disease. In the group with pelvic inflammatory disease by laparoscopy, admission examination suggested an inflammatory pelvic mass in 8 patients, which was confirmed by laparoscopy in 5; inflammatory masses were not detected on examination in 2 patients.

Of the 23 patients with laparoscopy-documented pelvic inflammatory disease, 11 were randomized to treatment with cefamandole and clindamycin and 12 to doxycycline and clindamycin. One patient from the former group was unevaluable; she was doing well on the second day of therapy when she left the hospital. Severity of illness was equivalent in the two groups by clinical and laparoscopic parameters. Both regimens yielded 100% efficacy with no significant differences in days of therapy to response. No significant adverse drug reactions were recorded. Only five patients attended the visit 1 month after discharge, and all were doing well. All patients were contacted at 10 days after discharge, and no subjective relapses occurred in either group in spite of termination of antibiotic therapy at

Table III. Microbiologic findings from the cervix and fallopian tubes of 23 patients with laparoscopy-documented pelvic inflammatory disease

Isolate	*Clindamycin + doxycycline*		*Clindamycin + cefamandole*	
	Cervix (n = 11)*	*Tubal (n = 10)*	*Cervix (n = 12)*	*Tubal (n = 8)*
N. gonorrhoeae	6	5	3	1
C. trachomatis	2	0	4	1
Aerobes and anaerobes	—	0	—	3†

*Number of patients with cultures taken from site; only one of 23 patients had both gonococci and chlamydia on cultures from the endocervix (in doxycycline group), and no patient had both these organisms in the upper tract.

hospital discharge. Our microbiologic findings are shown in Table III.

Combining the two treatment groups, days of therapy to response did not differ as a function of initial total sign score, temperature ≥38.0° C, white blood cell count ≥10,000/mm³, pelvic mass on physical examination, or old adhesions on laparoscopic examination. However, days to response for mild, moderate, and severe pelvic inflammatory disease by laparoscopic grading were 2.3 ± 0.5, 2.7 ± 1.5, and 3.9 ± 1.5, respectively ($p < 0.05$). Presenting temperature, white blood cell count, total symptom score, total sign score, and erythrocyte sedimentation rate showed no significant correlation with laparoscopic grade of disease. Sequential daily mean total sign scores during successful therapy were 15.9, 12.7, 8.6, 4.5, 2.8, 2.2, 2.1, 2.8, and 3.5; mean score on day of response was 4.4.

In Table IV each of the six variables assessed daily during therapy is examined for whether its requirement for response to therapy (as defined in Table I) had been achieved relative to the day the patient met composite criteria for response to therapy. On the day before qualification for therapeutic response, only 2 (9%) of the 22 patients had met the criterion for normalization of pelvic tenderness on bimanual examination, and in only 15 (68%) patients did this variable meet the criterion on the day of therapeutic response, when all five of the other variables had done so.

Comment

In the only study similar to ours, Sweet et al.[9] studied 29 women selected for inpatient therapy for pelvic inflammatory disease. The diagnosis was made by any four of (1) lower abdominal pain or (2) tenderness, (3) cervical motion tenderness, (4) adnexal tenderness, (5) fever, or (6) leukocytosis. Laparoscopy revealed the specificity of clinical diagnosis by their criteria to be 90%. Our study, like that of Jacobson and Westrom,[1] imposed no diagnostic criteria on physicians referring patients to the study. However, in spite of our application of criteria defining severe disease to these patients before enrollment, our specificity of clinical diagnosis (70%) was similar to that found by Jacobson and Westrom[1] (65%). We conclude that the diagnostic criteria for pelvic inflammatory disease employed by Sweet et al.[9] offer specificity superior to those used by individual clinicians in this and other existing studies and to our severe disease criteria; the false-negative diagnosis rate sustained by their criteria and the accuracy compared to existing guidelines[4] are not known. Standardization of diagnostic criteria for pelvic inflammatory disease seems desirable. Although our study was not designed to evaluate this issue, we do not wish to understate the importance of providing optimal medical therapy to all patients with pelvic inflammatory disease of any severity, particularly those who are young, nulliparous, or at risk for noncompliance, to minimize tubal injury and its sequelae.

In an analysis of patients studied by Jacobson and Westrom[1] who had a first episode, otherwise unclassified, of pelvic inflammatory disease, Hadgu et al.[10] identified the presence of purulent vaginal discharge and erythrocyte sedimentation rate ≥15 mm/hr as the strongest predictors of the presence of pelvic inflammatory disease. In patients having clinically severe pelvic inflammatory disease by our criteria, these two variables were not useful discriminators. Type II error may explain the failure of our study to confirm the value of certain historic features in diagnosis of pelvic inflammatory disease that others have shown, as reviewed by Eschenbach[11]—multiple sexual partners, genital symptoms in sexual partner, history of pelvic inflammatory disease, sexually transmitted disease, or ectopic pregnancy, and public funding. However, we believe that the practical clinical usefulness of these variables is truly limited by their high frequency in the subpopulation considered for a diagnosis of pelvic inflammatory disease, unwillingness of patients to divulge such information because of its negative connotations, or the fragmentary medical record often available when the patient is first seen. Our data do support the association between florid findings on physical exami-

Table IV. Status of individual outcome variables relative to satisfaction of composite criteria for therapeutic response* (n = 22 patients)

Pelvic mass	22	22	22

*See Table I and text for definition of variables and response criteria.

nation and documented pelvic inflammatory disease; lesser physical findings argue against it, regardless of other laboratory or historic data and even our clinical criteria for severe disease. Further, we found that the presence of bowel symptoms, lateralization of pelvic pain, and extension of pain to the upper abdomen do not argue against the diagnosis of pelvic inflammatory disease.

Rate of recovery, which may be considered a component in the definition of severity of disease, correlated among our patients only with laparoscopic grade of disease. Neither the presence of a pelvic mass by examination nor other data available without laparoscopy predicted rate of recovery, and none correlated with laparoscopic grade of disease. We take these data to support the accuracy and usefulness of the laparoscopic grading system. Because our clinical criteria for severe pelvic inflammatory disease were met by 10 (44%) of 23 patients with mild disease by laparoscopy, we cannot recommend the accuracy of these clinical criteria. Laparoscopy also provided an objective diagnosis for all 10 patients without pelvic inflammatory disease, who otherwise would have had continued illness or ineffective treatment until an accurate diagnosis was made later or not at all. However, we must caution that laparoscopy may yield false-negative results for pelvic inflammatory disease; exclusively endosalpingeal infection may occur without laparoscopically visible manifestations. A potential example of this phenomenon is our patient who had endocervical gonococcal infection and whose laparoscopic diagnosis was severe endometriosis.

Our outcome classification system, which also constitutes a management plan for inpatient therapy of pelvic inflammatory disease, is based on readily available clinical data. Its accuracy in defining adequate therapy is strongly supported by the absence of subjective evidence of relapsing disease in all of our patients. Although our criteria for therapeutic failure were not tested by this study population and would ethically be very difficult to test in any study, they represent the converse of the accurate response criteria and may be supported on that basis. Not only has this system been useful to us in subsequent therapeutic trials, but it is adaptable to general clinical use. We wish to emphasize that pelvic tenderness on bimanual examination (which can be performed from the bedside in <1 minute) is the most sensitive indicator of the need for continued treatment, as shown in Table IV. Because it is the one response variable that is abnormal at presentation in essentially all patients with pelvic inflammatory disease and that provides specific information about the site of infection, we strongly endorse its use. We find no data to support the concept that a brief, gentle daily pelvic examination could be detrimental to the patient's recovery. Our data also support the clinical applicability of the total sign score, which we adapted from Thompson et al.[12] A higher score significantly predicted the presence of pelvic inflammatory disease, and the mean sign score showed a linear decline during successful therapy until day 7, when only four patients remained.

Our two antibiotic combinations were designed to cover the bacterial spectrum encountered in pelvic inflammatory disease.[13] The high prevalence of *N. gonorrhoeae* in our area is reflected in the frequency of this organism in the lower and upper genital tract of patients in this study, 39% and 26%, respectively. Isolations of *C. trachomatis* from endocervix and oviduct were not as congruent (26% and 6%, respectively). Ten of the 18 tubal specimens (55%) grew a pathogen; our frequency of negative cultures is comparable to that in most reports on this subject. Both study drug regimens yielded 100% response rates by our criteria within a comparable interval, and there were no adverse drug reactions. Availability of our patients after discharge provided only for subjective assessment for relapsing infection, which did not occur with either regimen in spite of the absence of oral antibiotic therapy after discharge, a finding previously reported by Hager at al.[14]

for pelvic infections other than pelvic inflammatory disease. Nonetheless, we continue to recommend completion of 7 days' therapy for presumptive or documented chlamydial infection in this setting.

Fetal maternal laryngeal papillomatosis in pregnancy: A case report

George Helmrich, MD, Thomas M. Stubbs, MD, and Jay Stoerker, PhD
Charlotte, North Carolina

Although genital condylomata worsen with pregnancy, we are unaware of any reports of fatal maternal laryngeal papillomatosis. A maternal death at 20 weeks' gestation of a patient with chronic laryngeal papillomatosis is described. Pregnant patients with a history of this disorder who have symptoms should be considered candidates for immediate evaluation. (Am J Obstet Gynecol 1992;166:524-5.)

Key words: Laryngeal papillomatosis, pregnancy, papillomavirus

Genital condylomata are being diagnosed more frequently in gynecologic and obstetric practices in many areas of the United States. The tendency of these lesions to proliferate in the genital area during pregnancy has long been noted. Infrequently laryngeal papillomatosis develops in children; it is acquired at delivery and is caused by the same papillomavirus that causes the genital lesions. We are unaware of any previous case reports in the medical literature of maternal complications arising from the presence of laryngeal papillomatosis in the mother. The suddenly occurring maternal death in this case underscores the potential seriousness of laryngeal papillomatosis in pregnancy.

Case report

A 24-year-old woman, gravida 5, para 4, presented to our Obstetrical Clinic at 20 weeks' gestation. She was first diagnosed with laryngeal papillomatosis at age 2½,

with pathologic confirmation. Over the next 8 years she underwent numerous papillectomies by various physicians. The patient was untreated over the ensuing 15 years with apparent remission. Her only medical treatment from September 1985 to July 1990 was for gynecologic problems, spontaneous abortions, and delivery of infants without prenatal care. During this period she did not have respiratory distress, hoarseness, or audible respirations.

At the patient's first visit to the obstetric clinic during this pregnancy, she was noted to have audible respirations. She was not in respiratory distress. She did not keep the otolaryngology appointment that was scheduled at her first prenatal visit. At her next prenatal visit a second otolaryngology appointment was made, but the patient did not keep that appointment either. On her third visit she was noted to be hoarse with audible respirations but without respiratory distress. A third otolaryngology appointment was made for the patient. On the following day, the patient's family noted her to be in her usual state of health and without new respiratory symptoms. The next morning, she was found to be in acute, severe respiratory distress. On arrival at the hospital, she experienced a cardiopulmonary arrest, and intubation was difficult. She spontaneously aborted the next day and died on hospital day 10. Autopsy was refused. Histologic examination of the tissue recovered at the time of intubation revealed classic papillomatosis. A spot blot analysis indicated human papillomavirus type 6 or 11. A Southern blot confirmed type 11 virus.

Comment

This is apparently the first report of a maternal death from laryngeal papillomatosis during pregnancy. Although autopsy was refused, the diagnosis was histologically proved. The inciting event remains unknown and may have been a ball-valve effect or localized infection with edema. Whatever the immediate biologic mechanism, the certainty of laryngeal papillomatosis as the underlying cause requires obstetricians to be aware of the lethal potential of this disorder. Papillomavirus is becoming very widespread at the end of the 20th century; complications from maternal laryngeal papillomatosis in the future may not be as rare as they have been in the past. This patient had no obvious compromise to the immune system (including being human immunodeficiency virus negative), and the cause of reactivation of the disease at this time in her life is apparently attributable only to the pregnancy. Why this pregnancy and not prior ones would have caused such a problem is unclear.

The type 11 papillomavirus is one of the widely recognized genital condyloma types. Its finding is consistent with the patient's childhood disease and presumed acquisition at birth. Interestingly, human papillomavirus type 11 has generally and strongly been associated with nonaggressive disease.

The devastating effect of laryngeal papillomatosis has prompted many case reports of severely affected children. In 1871, MacKenzie[1] noted the frequent association of skin warts with laryngeal papilloma. Most current literature now suggests that approximately 60% of affected children have mothers with overt genital condyloma. With only one reported exception, all children with laryngeal papillomatosis have been delivered vaginally, thus suggesting that transmission is by direct contact rather than transplacentally.[2]

It is recognized that maternal condylomata frequently worsen with pregnancy. This heretofore unreported lethal complication of laryngeal papillomatosis suggests that pregnant women with even mild symptoms of laryngeal papillomatosis may benefit from aggressive otolaryngeal evaluation. Surgical intervention may be required during pregnancy.

The function of elevated plasma fibronectin in preeclampsia

Daniel B. Brubaker, DO,[a] Michael G. Ross, MD,[b] and David Marinoff, MD[b]
Torrance and Los Angeles, California

Total plasma fibronectin is elevated in preeclampsia due to vascular injury release, increased production, or enzymatic degradation resulting in multimers. To examine the etiology of the fibronectin increase in preeclampsia, we quantified plasma fibronectin in nonpregnant women, pregnant women from 28 to 42 weeks' gestation, latent labor, and preeclampsia by both nephelometry and turbidimetry. Western blotting and gel electrophoresis were used to examine the structural integrity of the fibronectin molecule. In addition, functional assays explored the potential for dysfunctional fibronectin. Fibronectin was elevated in pregnant patients compared with nonpregnant patients and exhibited a further significant increase with preeclampsia. The increase was not a result of degradation to multimers but possibly to increased variants. Notably, fibronectin function, as defined by collagen binding, may be impaired during pregnancy and preeclampsia. It appears that the clinical pathophysiology of preeclampsia may be related to dysfunctional fibronectin measured by collagen binding. (AM J OBSTET GYNECOL 1992;166:526-31.)

Key words: Fibronectin, preeclampsia, collagen binding

Fibronectins are large, usually dimeric, glycoproteins (molecular weight approximately 450,000 D) that are found both in a soluble form in plasma (plasma fibronectin) and in a larger, nonsoluble form in the extracellular matrix (cellular fibronectin).[1-4] Plasma fibronectin is synthesized primarily by hepatocytes[5,6] and is involved in opsonic activities with the reticuloendothelial system and in clot stabilization. Cellular fibronectin, synthesized by fibroblasts, endothelial cells, and astroglial cells among others, is involved in cell adhesion, migration, growth and differentiation.[1-3,7,8]

The various different fibronectins are derived from a single fibronectin gene and are composed of multiple domains. The exons making up the fibronectin gene correspond directly to functional domains of the protein. The sequence and presence or absence of the various domains accounts for the differing functional activities of the different fibronectins.[1-4,9] These activities include binding to fibrin, collagen, cells, and heparin. There are at least 12 versions of fibronectin,[3] although the fibronectin gene itself does not vary. These different variants are caused by alternative splicing of the messenger ribonucleic acid, which is subsequently translated into the fibronectin protein. Different cell types (hepatic, fibroblast, and endothelial) may synthesize different fibronectin variants. One of these variants is a soluble, plasma fibronectin containing an extra type III domain (ED1+)[10] found predominantly in large vessel endothelial cells[11] and in very small quantities in platelets.[10] The plasma fibronectin synthesized by hepatocytes lacks the ED1+ domain. Although the function of this variant is unclear, it has been associated with endothelial cell damage.[12] The association of elevated total plasma fibronectin and ED1+ fibronectin both in pregnancy and in gestational hypertension and preeclampsia have been documented in previous studies with a variety of methods (turbidimetry, nephelometry, quantitative electroimmunoassay, dual electrosorbent, enzyme-linked immunoassay [ELISA] method, Laurell immunoelectrophoresis).[13-22] The etiology of the elevation in plasma fibronectin in preeclampsia is uncertain. Although it may be related to vascular injury (elevated ED1+) characteristic of preeclampsia, the majority of plasma fibronectin is produced in the liver. Thus the etiology of the total fibronectin increase in preeclampsia remains uncertain, but there are several possibilities, which include (1) amniotic fluid leakage into the maternal circulation, (2) increased synthesis or release of fibronectin variants other than (but including) ED1+, (3) increased production of hepatic fibronectin (acute phase reactant), (4) endothelial cell damage (leakage), (5) increased proteolytic enzyme degradation of fibronectin, (6) increased platelet production of fibronectin, (7) increased tissue release of fibronectin secondary to vasospasm and hypertension, or (8) decreased renal clearance of fibronectin.

The purpose of this study is to investigate whether elevated plasma fibronectin results from monomers or multiple fragments and whether fibronectin is dys-

functional in this disease. We examine quantitative methods of fibronectin measurement (turbidimetry and nephelometry) as related to pregnancy, labor, and preeclampsia. We investigated the possibility that increases in fibronectin in pregnancy and preeclampsia are due to a structural change or cleavage to multimeric forms (by Western blotting and native gel electrophoresis) in the fibronectin molecule. Finally, we investigate functional assays of fibronectin (ELISA, Western blotting) to determine if the elevations of fibronectin in pregnancy and preeclampsia are caused by dysfunctional fibronectin.

Material and methods

We studied 82 patients divided into four groups: nonpregnant controls (10), pregnant control patients (23) at various nonlaboring gestational ages, pregnant patients (29) without preeclampsia in latent labor (cervix dilated <4 cm) at ≥36 weeks gestation, and patients (40) in labor with mild or severe preeclampsia at various gestational ages.[23] The pregnant controls and preeclamptic patients were subdivided into the following gestational age groups: 26 to 34 weeks, 35 to 38 weeks, and 39 to 42 weeks. We correlated fibronectin quantitation and function with gestational age to determine whether fibronectin was useful as a marker in the early detection of preeclampsia. Because most of the preeclampsia patients were only detected at delivery, we questioned the effect of labor on fibronectin We had no laboring patients before 36 weeks; therefore, all laboring controls were grouped in a category >36 weeks.

All patients and controls signed an informed consent form approved by the Human Subject Review Board of the Research and Educational Institute of Harbor–University of California, Los Angeles Medical Center. Blood samples were obtained by venipuncture and collected into citrated tubes. After centrifugation at 3000 rev/min for 10 minutes, plasma was frozen in multiple aliquots at −85° C.

Measurement of plasma fibronectin. Quantation of fibronectin by nephelometry and turbidimetry was performed as previously described by Brubaker et al.[24] We used undiluted rabbit anti-human fibronectin obtained from Biomedical Technologies, Inc. (Cambridge, Mass.) for the nephelometric method. The fibronectin standards, 1000 μg/ml (Biomedical Technologies, Inc., Cambridge, Mass., and Boehringer-Mannheim, Indianapolis, Ind.) was prepared at various dilutions to create a curve within the instrumentation. Controls of low (100 to 150 μg/ml), medium (300 to 500 μg/ml), and high (800 to 1000 μg/ml) were used between runs and for comparison with turbidimetric analysis.

The turbidimetric analysis was performed with the Boehringer-Mannheim Fibronectin (Opsonic Protein) assay kit. The suggested manufacturer's procedures were followed with a Gilfore Stasar III spectrophotometer.

The functional assay used in this study was a collagen-binding method with alkaline phosphatase–labeled fibronectin in a competitive inhibition assay. A modification of the method of Doran et al.[25] was used with soluble collagen, type X from human placenta (Type III, Sigma Chemical Co., St. Louis. Mo.) in the microtiter plates in place of gelatin. Several collagen types were tested in the modified Doran method; however, type X optimally bound fibronectin.

Fibronectin (native) protein electrophoresis was performed with 3% stacking polyacrylamide gels according to the method of Laemmli.[26] Fibronectin transfer by electrophoresis to nitrocellulose (Western blot) was similar to that of Towbin et al.[27] A fibronectin control was intentionally split into monomers with 2-mercaptoethanol at 37° C. Six antibodies were used in the immunoblotting method: polyclonal anti-human fibronectin, monoclonal antibodies to human fibronectin, monoclonal antibodies to human amniotic fibronectin, and monoclonal antibodies to fibronectin molecular domains for cell, heparin, and gelatin (collagen) attachment. All antibodies were obtained from Boehringer Mannheim Biochemicals (Indianapolis, Ind.).

Statistics. First- and second-order polynomial equations were used to describe the relationship of fibronectin values versus gestational age. Differences between the nonpregnant controls and pregnant controls, pregnant controls and pregnant patients in latent labor, and the three preeclamptic groups versus pregnant control groups were evaluated by unpaired t tests for each of the fibronectin assays. A Bonferroni correction was used for multiple comparisons in the three groups, with a $p \geq 0.0167$ considered significant. All results are expressed as mean ± SEM.

Results

The nonpregnant group consisted of 10 patients, seven nulliparous and three multiparous, mean age 35.3 ± 7.5 years. There were 23 pregnant control patients (nine nulliparous and 14 multiparous, mean age 24.2 ± 5.7 years). The mean fibronectin level was significantly greater in the pregnant versus nonpregnant patients as determined by nephelometry (433 ± 27 vs 252 ± 29 μg/ml; $p < 0.005$). There were no significant differences in fibronectin levels with turbidimetry (243 ± 20 vs 228 ± 15 μg/ml). With collagen binding, as determined with the ELISA method, the pregnant patients had significantly lower fibronectin values than nonpregnant controls (314 ± 51 vs 623 ± 35 μg/ml; $p < 0.005$).

The nonpreeclamptic patients in latent labor at ≥36 weeks' gestation consisted of nine patients (three nul-

Table I. Mean ± SEM fibronectin as determined by nephelometry, turbidimetry, and ELISA in preeclamptic and control pregnant patients at 26 to 34, 35 to 38, and 39 to 42 weeks' gestation

	26-34 weeks		*35-38 weeks*		*39-42 weeks*	
	Preeclamptic (n = 6)	*Control (n = 11)*	*Preeclamptic (n = 18)*	*Control (n = 6)*	*Preeclamptic (n = 16)*	*Control (n = 6)*
Nephelometry (μg/ml)	823 ± 39*	460 ± 42	873 ± 95*	338 ± 47	1064 ± 98*	478 ± 39
Turbidimetry (μg/ml)	430 ± 70*	229 ± 28	769 ± 128*	249 ± 52	647 ± 74*	263 ± 32
ELISA (μg/ml)	415 ± 90*	181 ± 42	450 ± 47	258 ± 47	515 ± 52	615 ± 97

*$p < 0.0167$ vs control.

liparous and six multiparous, mean age 22.4 ± 5.8 years). Eleven pregnant patients (five nulliparous and six multiparous, mean age 24.5 ± 6.4 years) not in labor and without preeclampsia at ≥36 weeks were used as controls to examine the effect of labor. Nonlaboring and laboring patients had similar fibronectin values by nephelometry (411 ± 39 vs 354 ± 55 μg/ml) and turbidimetry (264 ± 30 vs 268 ± 16 μg/ml). However, laboring patients demonstrated significantly lower fibronectin values by ELISA as compared with nonlaboring patients (273 ± 33 vs 458 ± 78, $p < 0.05$).

The best correlation of plasma fibronectin levels with gestational age was obtained with a second-order polynomial equation. For turbidimetry the equation is fibronectin = $2496.813 - 135.92\ (GA)^2 + 2.009$, $r = 0.46$, where GA is gestational age. For ELISA the equation was fibronectin = $4204.604 - 270.087\ (GA)^2 + 4.474$, $r = 0.75$. There was not a good correlation with nephelometry ($r = 0.05$).

There were a total of 40 preeclamptic patients (34 nulliparous and six multiparous, mean age 21.8 ± 4.6 years). When compared with control pregnant patients, preeclamptics had significantly higher levels of fibronectin with nephelometry and turbidimetry at all gestational ages (Table I). Statistically significant increases in collagen determined fibronectin was demonstrated only at 26 to 34 weeks' gestation.

All patient and control samples were immunoblotted (Western blot) to observe disulfide split into monomers or proteolytic cleavage into multimers with a polyclonal anti-human fibronectin. Sample 2 (Fig. 1) represents intentional disulfide splitting of the fibronectin molecule into monomers (second band) with a molecular weight of 220,000 D, whereas the first band represents the intact 440,000 D fibronectin molecule. In severe preeclampsia (sample 1), mild preeclampsia (sample 3), and normal pregnant control; (sample 4), the fibronectin molecule was intact for the polyclonal antibody and the monoclonal antibodies to gelatin (collagen-binding domain), heparin (aminoglycan-binding domain), and cell attachment domain on the fibronectin molecule. Fig. 1 is representative of all the patients' results.

Comment

Plasma fibronectin as determined by various methods is increased in normal pregnancy as compared with the nonpregnant state[17, 28, 29] and further increased in preeclampsia and gestational hypertension.[13-22] In the present study, we confirmed an increase in total plasma fibronectin by nephelometry, although not by turbidimetry. Studies by Thurneau et al.[18] with nephelometry, Eriksen et al.[17] with quantitative electroimmunoassay, and Hess et al.[28] and Brady et al.[29] with turbidimetry demonstrated increased fibronectin in the third trimester of normal pregnancy as compared with the nonpregnant state. Perhaps the difference in our results with nephelometry and turbidimetry is due to the increased sensitivity of nephelometry in detecting fibronectin variants in plasma.

There was no correlation between gestational age and fibronectin values with the nephelometry method. Turbidimetry showed values similar to those of nonpregnant controls throughout the third trimester, although these values tended to increase before 28 weeks and after 40 weeks ($r = 0.46$). Studies by Saleh et al.[19] (nephelometry), Ballegeer et al.[20] (immunoelectrophoresis), and Lockwood and Peters[21] (by dual ELISA method) with total plasma fibronectin did not show a rise in fibronectin values with advancing gestational age, although Hess et al.[28] (by turbidimetry) showed an increase in plasma fibronectin in pregnancy only in the third trimester. The ED1+ fraction did increase with gestational age in Lockwood and Peters' study.[21]

The results of the ELISA assay for collagen binding as a single assay can be interpreted as a measure of fibronectin dysfunction or the presence of a fibronectin variant. If the quantity is decreased in this assay, the fibronectin is dysfunctional in its ability to bind collagen (most likely interpretation) or there is a decrease in a collagen-binding variant. An elevation in this assay indicates a rise in a variant that is collagenophilic (most likely) or there is increased functional binding. The ELISA values as a single test were highly correlated with gestational age. Although low throughout the third trimester, the levels approached values of nonpregnant women near term. The decrease in ELISA

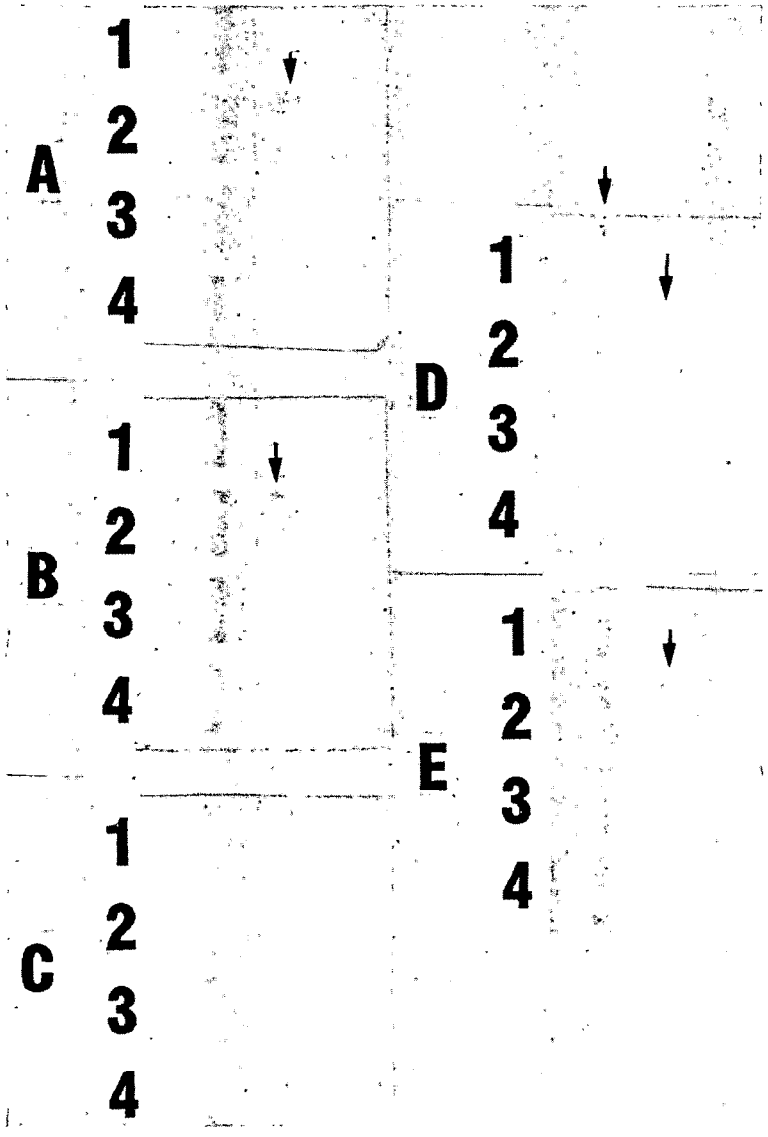

Fig. 1. Immunoblotting of samples from patient with severe preeclampsia *(lane 1)*, from intentionally split fibronectin *(lane 2)* with the monomer band below *arrow*, from patient with mild preeclampsia *(lane 3)*, and from normal pregnant control *(lane 4)*. The antibodies used to detect the fibronectin bands are **A,** monoclonal antibody to amniotic fluid fibronectin; **B,** monoclonal antibody to the cell-binding domain of fibronectin; **C,** monoclonal antibody to the collagen-binding domain of fibronectin; **D,** polyclonal antibody to fibronectin; and **E,** monoclonal antibody to heparin-binding domain of fibronectin.

values in pregnant patients possibly indicates that fibronectin may be dysfunctional for collagen binding in pregnancy. Labor did not affect fibronectin values as determined by nephelometry and turbidimetry, confirming the findings of Saleh et al.[18] and Brady et al.[29] The decreased ELISA values with labor may reflect further dysfunction of the fibronectin molecule. We have no definitive interpretation of the ELISA, but several biologic explanations are prudent. The decreased collagen binding in healthy pregnant women (gravid controls) in comparison with nongravid controls may be due to a healthy pregnant woman's response to a developing fetus, which is similar to the fibronectin response found in tumorigenesis.[4] This may represent dysfunctional fibronectin that becomes functional at term (third trimester levels are equivalent to nongravid levels) due to full development of the fetus. Another explanation for the increase in collagen binding near term may be a factor elaborated by the placenta, which is responsible for the decreased binding earlier in pregnancy, and with placental aging the production of this factor may diminish. The decrease found during de-

livery may represent lesser biologic collagen binding due to the release of the fetus at delivery. However, our ELISA assay must not be interpreted as a single assay but in conjunction with the quantitative results. The lack of increase in collagen binding by the ELISA assay in preeclampsia along with the increase in total fibronectin indicates either the secretion of a functionally altered fibronectin variant(s) or a circulating factor that alters collagen-binding.

Stubbs et al.[13] originally postulated that the increased plasma fibronectin is a result of release from damaged endothelial cells or a result of increased endothelial cell synthesis. Serum from preeclamptic women was found to be cytotoxic to cultured endothelial cells,[30] suggesting release of fibronectin from injured endothelium. The association of variant ED1+ fibronectin with endothelial cell injury and the discovery of elevated ED1+ fibronectin in preeclampsia[21] further substantiates the endothelial cell injury hypothesis. However, the endothelial injury theory is not fully substantiated and requires further study. Our nephelometry method suggests variants exist in normal pregnancy and in preeclampsia, because total fibronectin values are higher with nephelometry than turbidimetry. This finding is especially obvious when comparing nephelometry and turbidimetry in the experimental subjects (normal pregnancy and preeclampsia) with nonpregnant controls, where there is no significant quantitative difference between the methods in the nonpregnant women but there are differences in the experimental subjects. This finding results from the increased sensitivity of nephelometry. Increased sensitivity is due to amplification of a small signal on the black background in nephelometry compared with detecting an intermediate decrease in a large signal in turbidimetry.

No previous study has evaluated proteolytic cleavage of fibronectin into multimers or fragments. This also is a potential explanation of the elevated fibronectin in preeclampsia, especially because all quantitative methods are immunoassays. The results of immunoblotting have demonstrated that the 440,000 D fibronectin molecule is totally intact in preeclampsia. Using the monoclonal antibody to amniotic fluid fibronectin, the bands appeared wider and stronger in pregnant women and accentuated in severe preeclampsia. A quantitative assay will further delineate this observation.

The explanation for elevated fibronectin in preeclampsia still remains an enigma. In summary, pregnancy is associated with an increase in total fibronectin by nephelometry with a further increase by both nephelometry and turbidimetry in preeclamspia. The decrease in fibronectin function (ELISA-measured collagen binding) in normal pregnant patients and the lack of increase in patients with preeclampsia (>34 weeks) suggests either the secretion of functionally altered fibronectin variant(s) or a circulating factor of pregnancy that alters fibronectin function.

We thank Chris Mori, RN for recruiting patients and obtaining samples for this study. We also wish to thank Terrina Lam, MT (ASCP), Marianne Mangune, MT (ASCP), and Andrea Hutchinson, BS, for their technical assistance.

The Zavanelli maneuver applied to locked twins

J.M. Swartjes, MD, O.P. Bleker, MD, PhD, and M.F. Schutte, MD, PhD
Amsterdam, The Netherlands

The Zavanelli maneuver was applied to locked twins. After the first infant was returned into the vagina, an emergency cesarean section was performed. After a not-too-good start, both children did well. The Zavanelli maneuver is presented as a method to reverse the potentially catastrophic situation of locked twins. (AM J OBSTET GYNECOL 1992;166:532.)

Key words: Zavanelli maneuver, twins, locked twins

The Zavanelli maneuver is indeed a revolutionary concept for handling obstructed delivery.[1] The results have indicated that return into the vagina of a partially delivered infant and subsequent cesarean section might have a better neonatal outcome than forced completion of vaginal delivery. This case report describes the successful application of the Zavanelli maneuver to locked twins.

Case report

A 33-year-old secundigravid woman was expecting twins. The diagnosis was made in early pregnancy by ultrasonography, which demonstrated two separate gestational sacks, both with living fetuses. At 36 weeks 6 days' gestation she was admitted to the hospital with spontaneous rupture of the membranes of the first fetus. Except for a slight rise in diastolic blood pressure, the course of pregnancy had been uneventful. Uterine fundal height and ultrasonographic measurements showed satisfactory fetal development.

While labor progressed, the positions of both fetuses were determined by ultrasonography. The first fetus was in a breech presentation, and the second one was in a position between transverse and head down (head at the level of the maternal umbilicus). Because of the position of the second child, the risk for interlocking was estimated to be small. Vaginal delivery was accepted. Frequent ultrasonographic localization of the head of the second child was performed. At 18 minutes after active pushing had begun, the breech of the first child crowned at the vulvar ring. At this time we could not localize the head of the second child. With the next contraction the first child was delivered to the lower edges of the shoulder blades. Further delivery was impossible. On vaginal examination interlocking was recognized. We returned the partially delivered first infant into the vagina (moderate force was required). Emergency cesarean section was performed 10 minutes later, and two female infants were delivered. The Apgar scores of the first child after 1 and 5 minutes were 1 and 4; those of the second child were 2 and 4. Birth weights were 2580 and 2000 gm, respectively. Both children were cared for on the neonatal ward and both did well. Twelve days after cesarean section the two girls left the hospital with their mother.

Comment

Interlocking is a rare complication of twin delivery with a high mortality, especially for the first child. Pushing up the head of the second child or performing a cesarean section may be possible in the early stage. As interlocking proceeds, e.g., after breech extraction is attempted, few possibilities remain. In the case of a large pelvis or small fetal mass the Kimball-Rand procedure can be of help. If not, sacrificing one child to save the other might be the only remaining option.

The current case is the second report in the literature of the application of the Zavanelli maneuver to locked twins. Iffy et al.[2] were confronted with interlocking during preparation for elective cesarean section. After interlocking was recognized, it took only 3 minutes until abdominal delivery. The first child was born by traction to the head combined with pushing to the breech. In our case the child was completely returned into the vagina before an emergency cesarean section was performed about 10 minutes later. In our opinion the Zavanelli maneuver can be of help to reverse the potentially catastrophic situation of locked twins.

Radical hysterectomy for treatment of cervical cancer: A prospective study of two methods of closed-suction drainage

Desmond P.J. Barton, MD, Denis Cavanagh, MD, William S. Roberts, MD, Mitchel S. Hoffman, MD, James V. Fiorica, MD, and Michael A. Finan, MD
Tampa, Florida

Two closed-suction drainage methods were prospectively compared in 96 patients after radical hysterectomy with pelvic lymphadenectomy in stage IB cervical cancer. In group 1 (n = 49) two pelvic sidewall drains and a vaginal drain were used, and in group 2 (n = 47) only the vaginal drain was used. The groups were similar for mean age, preoperative weight, hemoglobin and serum albumin level, operating time, operative blood loss, and blood transfusions. The febrile morbidity rates and the operative site infection rates were similar in the two groups. Ninety vaginal drains were removed by day 3. By day 6 55% of patients in group 1 had at least one sidewall drain, with a mean drainage of 150 ml/day. The median postoperative stay was similar in both groups. A pelvic lymphocyst developed in one patient in each group. The single vaginal closed-suction drain is safe, efficient, more acceptable to patients, and more cost-effective. (Am J Obstet Gynecol 1992;166:533-7.)

Key words: Radical hysterectomy, cervical cancer, closed-suction drains

The early stages of invasive carcinoma of the cervix are treated by either radical surgery or radiotherapy.[1] Although not universal, traditional surgical practice after radical hysterectomy and pelvic lymphadenectomy has been to reapproximate the pelvic peritoneum and to drain the pelvis. Pelvic drainage, recommended because of increased pelvic fluid formation, was used to prevent pelvic hematomas and reduce postoperative pelvic infection, pelvic lymphocyst formation, and ureteral complications.[2, 3]

The benefit of prophylactic antibiotics in reducing infectious morbidity, however, seemed unclear.[4, 5] Furthermore, the value of and the method of prophylactic drainage have remained controversial, and inappropriate drainage has been associated with significant morbidity.[6-8] Currently, closed-suction drainage systems with low-pressure vacuum reservoirs are advocated.[6-8] In this division two closed-suction pelvic sidewall drains and a closed-suction vaginal drain have been used after radical hysterectomy and pelvic lymphadenectomy,[5] but this method may not confer any advantage over a single, closed-suction vaginal drain. It was hypothesized that one vaginal suction drain would not reduce pelvic fluid drainage, duration of use, and rate of pelvic soft tissue infection or increase patient acceptability compared to one vaginal and two sidewall drains. Because pelvic drainage methods after radical hysterectomy and pelvic lymphadenectomy have received little specific attention in recent gynecologic literature, a prospective study was undertaken to test this hypothesis.

Material and methods

Between July 1987 and November 1990, 96 patients who underwent a radical hysterectomy and bilateral pelvic lymphadenectomy for treatment of stage IB (International Federation of Gynecology and Obstetrics) invasive carcinoma of the cervix were entered in the study. All operations were performed by members of the Division of Gynecologic Oncology. No patient received radiotherapy before surgery. The preoperative procedure for all patients included a mechanical bowel preparation (without antibiotics). The operative procedure was standard with a vertical midline abdominal incision followed by a Rutledge type III operation[9] with a selective paraaortic lymphadenectomy. The pelvic peritoneum was not reapproximated. In younger patients the ovaries were conserved and transposed. The abdominal wall was closed with the continuous mass-closure technique[10] with either No. 2 polyglactin suture (Vicryl; Ethicon, Somerville, N.J.), or No. 1 polyglyconate (Maxon; Davis and Geck, Danbury, Conn.). The method of bladder drainage was transurethral with an 18F Foley catheter left in situ for approximately 6 weeks, during which time patients received prophylactic nitrofurantoin, 100 mg daily.

When three drains were used, one drain (T tube) was brought out through the vagina, and each of the other drains was placed at the pelvic sidewall and brought

out extraperitoneally through the anterior abdominal wall.[5] The rectosigmoid colon was mobilized into the pelvis to reduce the pelvic depth and prevent small bowel from adhering in the pelvis. All three drains were attached to low suction. The vaginal drain was a round 19F, 6.3 mm outer diameter, Jackson Pratt T-tube hysterectomy drain (Heyer-Schulte, American V. Mueller, Chicago). The pelvic sidewall drains were flat (Jackson-Pratt Hubless 10 mm flat silicone drains, 20 cm × 10 mm × 4 mm). Each drain was attached to a soft, pliable, closed-suction 100 ml reservoir that has an antireflux valve (Meyer-Schulte, American V. Mueller, Chicago). Patients operated on between July 1987 and June 1989 had the vaginal T tube and two sidewall drains, and those patients operated on after June 1989 had the vaginal T-tube drain only.

All patients received prophylactic antibiotics 1 hour before surgery and then 6 hours and 12 hours after surgery. Antithrombotic measures were prophylactic heparin, 5000 U subcutaneously, before surgery and every 12 hours thereafter, or Venodyne compression boots (Advanced Instruments, Inc., Needham Heights, Mass.) until the patient was fully ambulatory. More recently only the latter method has been used except in patients with a history of thromboembolism. The volume of fluid from each drain was measured daily. The drains were removed if the volume collected in 24 hours was <30 ml. Postoperative febrile morbidity was strictly defined as two consecutive oral temperatures of >38° C (100.4° F) 4 hours apart, excluding the first 24 hours after surgery. Two consecutive temperatures >38° C represented failure of antibiotic prophylaxis, and patients were treated with other antibiotics. The causes of febrile morbidity were defined as operative site infection (pelvis), non-operative-site infection (for example, chest infection or urinary infection), and source unknown. In the absence of any known non-operative-site infection and in the presence of persistent febrile morbidity the source was presumed to be a pelvic soft tissue infection.[4, 5, 11-13] Results in the two groups were compared by χ^2 analysis for dichotomous measurements and the Student t test for continuous measurements. The level of significance was $p < 0.05$.

Results

There were 49 patients with a vaginal drain and two pelvic sidewall drains (group 1) and 47 with the vaginal drain only (group 2). Aside from the chronologic allocation of patients to the two groups there was no identifiable selection bias. The two groups had similar demographic features (Table I). More patients ($p > 0.05$) in group 2 had metastatic nodal disease (Table II). Intraoperative blood loss was similar in patients receiving heparin and compression boots.

The drainage volumes for the first 3 postoperative days are shown in Table III. The vaginal T tube was

removed on the third postoperative day, except in three patients in each group in whom it was removed on day 4. No patient complained of vaginal drainage after the drain had been removed. In group 1 most of the drainage was from the pelvic sidewall drains and remained high, so that by day 7 27 patients (55.1%) had at least one sidewall drain (Table IV). The volume of pelvic drainage was not related to patient weight, operative time, blood loss, or method of thrombotic prophylaxis. The prolonged continued use of the sidewall drains was a source of patient inconvenience and discomfort.

The incidence and causes of febrile morbidity in the two groups are comparable (Table V). No patient had serious surgical site infection. Forty-six of the 96 patients (47.9%) had febrile morbidity. Twenty-two (22.9%) had operative site infection, but their drainage volumes were similar to those of patients who had no febrile morbidity. Fifteen (15.6%) patients had metastatic nodal disease. Ten of these had postoperative febrile morbidity, compared with 34 of 81 patients without nodal disease ($p < 0.05$). Half of these patients with febrile morbidity, regardless of nodal status, had surgical site infection. In group 1 the mean vaginal drainage volumes were similar in those with and without nodal disease. Although there was an impression of greater sidewall drainage in the first three postoperative days in node-positive compared with node-negative patients, meaningful statistical analyses were not applicable because only four patients in group 2 had positive nodes. In group 2 the mean daily vaginal drainage volumes were similar in node-positive and node-negative patients. The mean total daily drainage volumes for the first three postoperative days were similar in the node-negative (n = 81) and node-positive patients (n = 15).

The median postoperative stay was 7 days (range 6 to 15) in group 1 and 6 days (range 6 to 16) in group 2. There have been two pelvic lymphocysts, one in each group, both asymptomatic and detected clinically at 2 and 12 weeks after surgery. Both patients had metastatic pelvic nodal disease. There were no pelvic abscesses or ureterovaginal fistulas.

Comment

The results indicate that one vaginal closed-suction drain was a safe, effective alternative to two pelvic sidewall drains and a vaginal drain after radical hysterectomy and bilateral pelvic lymphadenectomy in stage IB cervical cancer. Furthermore, patients with pelvic sidewall drains continued to have significant pelvic drainage after the vaginal drain had been removed. How-

ever, the pelvic soft tissue infection rates in the two groups were comparable.

Variables such as the type of drain (closed or open, suction or nonsuction), the number of drains used, and whether the pelvic peritoneum was approximated have often not been considered in reports on morbidity from radical hysterectomy where, in addition, the surgical technique has differed.[3-4, 11-13] This makes it difficult to determine what factors are important in morbidity. In this study the surgical technique was standardized. We used closed-suction, low-pressure drainage systems, which have been advocated in other studies and which are associated with less ascending infection and less trauma to healing tissues, including the peritoneum.[6, 14-16]

One aim of pelvic drainage is to reduce lymphocyst formation, the incidence of which, after radical surgery in cases of cervical cancer, varies,[17-19] with reports of almost 50%.[19] Because not all of the lymphatics can be removed or ligated at a lymphadenectomy and lymph fluid is produced continually, a low incidence of lymphocyst formation might be expected, regardless of the method of drainage. In contrast, pelvic drains have been reported to increase the incidence of lymphocyst formation.[17, 18] Most pelvic lymphocysts are detected in the early postoperative period,[17-19] as in the two cases recorded in this study. It had been suggested that nonclosure of the pelvic peritoneum would reduce lymphocyst formation, but this was not confirmed in early reports.[18, 19] It has also been suggested that one reason lymphocysts do not follow all lymphadenectomies is that lymph fluid escapes into the peritoneal cavity, where it is absorbed.[19] This is of interest because a treatment of pelvic lymphocysts has been marsupialization.

The peritoneum has highly efficient reparative[20, 21] and absorptive[22] capacities, and closure of the pelvic peritoneum, while arguably unnecessary, is also time-consuming and may be associated with trauma to adjacent structures, such as the ureter.[15, 20] Damaged peritoneum heals normally without adhesions unless infection, ischemia, or foreign bodies are present.[20, 21] A pelvic drain could, if left in situ for some days, impair the reparative and absorptive capacities of the peritoneum and so contribute to the very problems its use was intended to prevent.[15] This suggests that drains at peritoneal surfaces should be removed early or not be used at all.

The two cases of pelvic lymphocysts were in patients with nodal metastases in whom pelvic drainage and lymphocyst formation[18] is reported to be higher. We found no significant difference in the mean daily drainages in node-positive compared with node-negative patients, either within each group or in the study population as a whole. We did observe, however, that patients in group 1 continued to have high drainage after the vaginal drain had been removed. This suggests that either these low-pressure pelvic side wall drains contributed to the continued pelvic drainage[17] (by maintaining patency of lymph vessels and reducing the absorptive capacity of the peritoneal surfaces) or the drainage was absorbed effectively in group 2 by the peritoneal surfaces.[22]

Pelvic drainage fluid contains electrolytes and protein, and continued fluid loss is not in the patient's best interest.[23, 24] Many patients with cervical cancer are nutritionally depleted before treatment and usually more so after treatment.[25] Group 1 patients had high total drainage volume (≥1 L compared with <200 ml in group 2). High pelvic drainage has been previously reported with sidewall drains.[3, 11, 24] The high pelvic drainage in group 1 continued to postoperative day 6 in more than half the patients. Other studies with different drainage methods and varying surgical techniques reported high loss on the first day or up to the third[23] and fifth days.[24] A previous study reported no difference in total pelvic drainage in patients with two and one drain,[24] but different surgical procedures had been performed in that study. Our results clearly show a higher total volume of drainage in patients with three drains. Prolonged use of drains also caused inconvenience and discomfort for the patients and was associated with a trend toward increased hospital stay.

Febrile morbidity is common after radical hysterectomy but serious postoperative infections are not and no serious operative site infections occurred. The febrile morbidity rates due to surgical site infection in the two study groups were similar and comparable to those in other reports.[3-5, 11-13] In a larger number of patients a significant difference between the two groups might have been demonstrated. Patients who had surgical site infection ($n = 22$) had mean daily total drainage volumes similar to those of patients without febrile morbidity ($n = 50$). In fact, a sudden drop in drainage volume was viewed as possibly representing blockage of a drain, and such drains were carefully stripped. Patients with metastatic nodal disease were more likely to have surgical site infection than those without nodal disease. This association was not reported in the studies reviewed.[3-5, 11-13] Febrile morbidity was not associated with low or high pelvic drainage, as reported previously.[24]

To our knowledge, this is the first prospective study to specifically compare the value of different drainage methods after radical hysterectomy and pelvic lymphadenectomy for stage IB cervical cancer. Patients with pelvic side wall drains had prolonged drainage. This was associated with increased patient discomfort, inconvenience, and expense (about $100 for drains and cost of increased hospitalization). On the basis of these facts we recommend that, in addition to not reapprox-

imating the pelvic peritoneum, a single closed-suction, low-pressure vaginal T-tube drain be used. This is now our practice for all patients undergoing radical hysterectomy and pelvic lymphadenectomy.

Bound volumes available to subscribers

Bound volumes of the American Journal of Obstetrics and Gynecology are available to subscribers (only) for the 1992 issues from the Publisher, at a cost of $68.00 for domestic, $95.76 for Canada, and $91.00 for international for Vol. 166 (January-June) and Vol. 167 (July-December). Shipping charges are included. Each bound volume contains a subject and author index and all advertising is removed. Copies are shipped within 60 days after publication of the last issue in the volume. The binding is durable buckram with the Journal name, volume number, and year stamped in gold on the spine. *Payment must accompany all orders.* Contact Mosby—Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318, USA; phone (800) 325-4177, ext. 4351, or (314) 453-4351.

Subscriptions must be in force to qualify. Bound volumes are not available in place of a regular Journal subscription.

Arterial pressure response to maximal isometric exercise in pregnant women

Fred K. Lotgering, MD, PhD, Akkeliene van den Berg, BSc, Piet C. Struijk, BSc, and Henk C.S. Wallenburg, MD, PhD

Rotterdam, The Netherlands

We studied the arterial pressure response to maximal leg exercise in 15 healthy volunteers at 29 and 35 weeks' pregnancy and at 8 weeks post partum. Resting mean arterial pressure at 35 weeks' gestation was similar to the postpartum control value of 88 mm Hg (range 73 to 111), but it was reduced by 10% at 29 weeks' gestation. Voluntary maximal effort averaged 2470 N (range 1450 to 3030) in the postpartum period, was similar at 29 weeks, and was reduced by 13% at 35 weeks' gestation. Mean arterial pressure showed a linear increase with force to a median maximum value of 131 (104 to 159) mm Hg, or 49% above the resting value in the postpartum period. The pressure response was unaffected by pregnancy, but was inversely related to maximal force, i.e., the individual's capacity to perform isometric exercise. (Am J Obstet Gynecol 1992;166:538-42.)

Key words: Pregnancy, maximal exercise, isometric exercise, blood pressure

Pregnancy and muscular exercise require physiologic adaptations to increase blood flow to the regions of the body with increased metabolic activity: the uterus and the exercising muscles. The cardiovascular responses to pregnancy and to dynamic exercise include an increase in cardiac output, through increases in heart rate and stroke volume, with a reduction in peripheral vascular resistance. As a net result of these changes, systemic blood pressure usually falls slightly during pregnancy, whereas it increases mildly during dynamic exercise.[1] The adaptations are so effective that the combined demands of pregnancy and dynamic exercise do not appear to compromise the healthy fetus[1-3] nor affect the capability of healthy pregnant women to perform dynamic aerobic exercise.[3]

In contrast to dynamic exercise in which muscles undergo shortening or lengthening, isometric exercise does not result in muscle movement. Sustained muscle activity not only induces local vasodilatation but also muscle ischemia and mechanical obstruction to muscle perfusion.[4] Therefore, isometric exercise elicits a different cardiovascular response, with a more pronounced increase in arterial pressure than that during dynamic exercise. The mechanisms of these responses have recently been reviewed[5] and will be discussed in Comments. The magnitude of the response is dependent on the strength and duration of muscular contraction.[4]

The combined effect of isometric exercise and pregnancy has only been studied by means of handgrip exercise.[6-8] However, in handgrip exercise the active muscle mass is relatively small and the required force cannot be accurately determined. In the present longitudinal study we investigated the effects of pregnancy on the capability of the body to perform strenuous isometric exercise, and we determined blood pressure and heart rate responses to such exercise.

Material and methods

We studied 15 healthy women at 29 and 35 weeks of pregnancy and at 8 weeks post partum. All women were healthy, normotensive, and had uncomplicated singleton pregnancies, but they varied with regard to body weight and physical fitness. All women included in the study gave their informed consent. The study was approved by the Hospital and University Ethics Committee.

The women performed isometric exercise in an air-conditioned room kept at 21° C and at 60% humidity. Before each test we performed a routine physical and obstetric examination and monitored fetal heart rate (Corometrics, Fetal monitor 111, Wallingford, Conn.) to confirm the health of both individuals participating in the study. In addition, we determined body weight and leg length, from heel to trochanter major. The woman was placed on an ergometer designed for this study (Central Research Workshop, EUR, Rotterdam, the Netherlands). It consisted of a chair with a horizontal, adjustable footboard. The distance between the back of the chair and the footboard was adjusted to

90% of the length of the woman's legs and was kept constant between measurements within each individual. After 15 minutes of rest on the ergometer, the force exerted on the footboard was progressively and stepwise increased by 400 N per increment, until voluntary maximum effort was reached. Efforts of 45 seconds' duration were separated by 2 minutes of rest. The force exerted on the footboard was measured electronically with calibrated strain gauges and found to be accurate within 1% over the full range of measured forces. Heart rate and systolic, mean, and diastolic arterial blood pressures were measured oscillometrically (Dinamap 845, Applied Medical, Tampa, Fla.), a method validated for the observed range of measurements.[9] Measurements took 20 to 45 seconds to be completed and were initiated 2 minutes before and at the onset of exercise. During the exercise the volunteer was encouraged to continue to breathe normally and not to use her arm muscles.

Each woman underwent an initial test to get used to the experimental circumstances; the data obtained in this test were discarded. The Friedman and Wilcoxon ranked-sign tests were used to analyze differences between paired variables. Linear regression analysis was used to assess relationships between variables within each individual; the slopes and intercepts were treated as variables. A p value of <0.05 was taken as the level of significance.

Results

All 15 women remained healthy throughout the study period and were delivered of healthy infants. Median age at the time of delivery was 28 (range 24 to 34) years, gestational age 40 (37 to 42) weeks, and birth weight was 3.4 (2.6 to 3.9) kg.

All women were studied at 29 (26 to 32) weeks and 35 (33 to 37) weeks of pregnancy and 8 (6 to 10) weeks after delivery. Body weight was 72 (54 to 96) kg at 29 weeks, 74 (59 to 99) kg at 35 weeks' gestation, and 68 (50 to 93) kg 8 weeks post partum. Median leg length was 92 (78 to 98) cm. Six women were lactating at the time of the postpartum test. Because their responses did not differ significantly from those in the other women, we report the combined data.

The effects of pregnancy on values of heart rate and blood pressures at rest and at maximal exercise are summarized in Table I. Heart rate at rest was consistently increased during pregnancy above the median postpartum value of 78 beats · min^{-1}. Arterial blood pressures at rest were significantly below postpartum values at 29 weeks' gestation, but they were not markedly different at 35 weeks of pregnancy. Maximal force was not significantly different from the median postpartum value of 2470 N at 29 weeks' gestation, but at 35 weeks' gestation maximal force was significantly lower than at 29 weeks and post partum, by −3% to −13%, in 11 and 13 of the 15 women, respectively. Heart rate during maximal isometric exercise in pregnancy was significantly elevated by 3% to 10% above the postpartum value of 119 beats · min^{-1}, whereas systolic, mean, and diastolic pressures were not significantly different among the three periods.

Heart rate and systolic, mean, and diastolic pressures were linearly related to force and to each other (median $r = 0.96$, range 0.70 to 0.99). This is shown for heart rate and mean arterial pressure in Figs. 1 and 2. Pregnancy did not significantly affect the slope of any of the lines. In contrast, Fig. 2 demonstrates that the position of the mean arterial pressure-heart rates lines are affected by pregnancy, as are the values of heart rate and blood pressure at rest.

The individual's capacity to perform isometric leg exercise was unrelated to body weight and to maximal values of heart rate or arterial pressures. However, the systolic, mean, and diastolic arterial pressure responses were inversely related to performance. The mean arterial pressure response to a change in force can be expressed as Δmean arterial pressure/Δforce = $-0.007 \times$ maximal force (kN) + 35 ($r = 0.70$, $p = 0.004$) and varies from 24 mm Hg/kN at a maximal force of 1.5 kN to 13 mm Hg/kN at 3 kN. The relationship is unaffected by pregnancy.

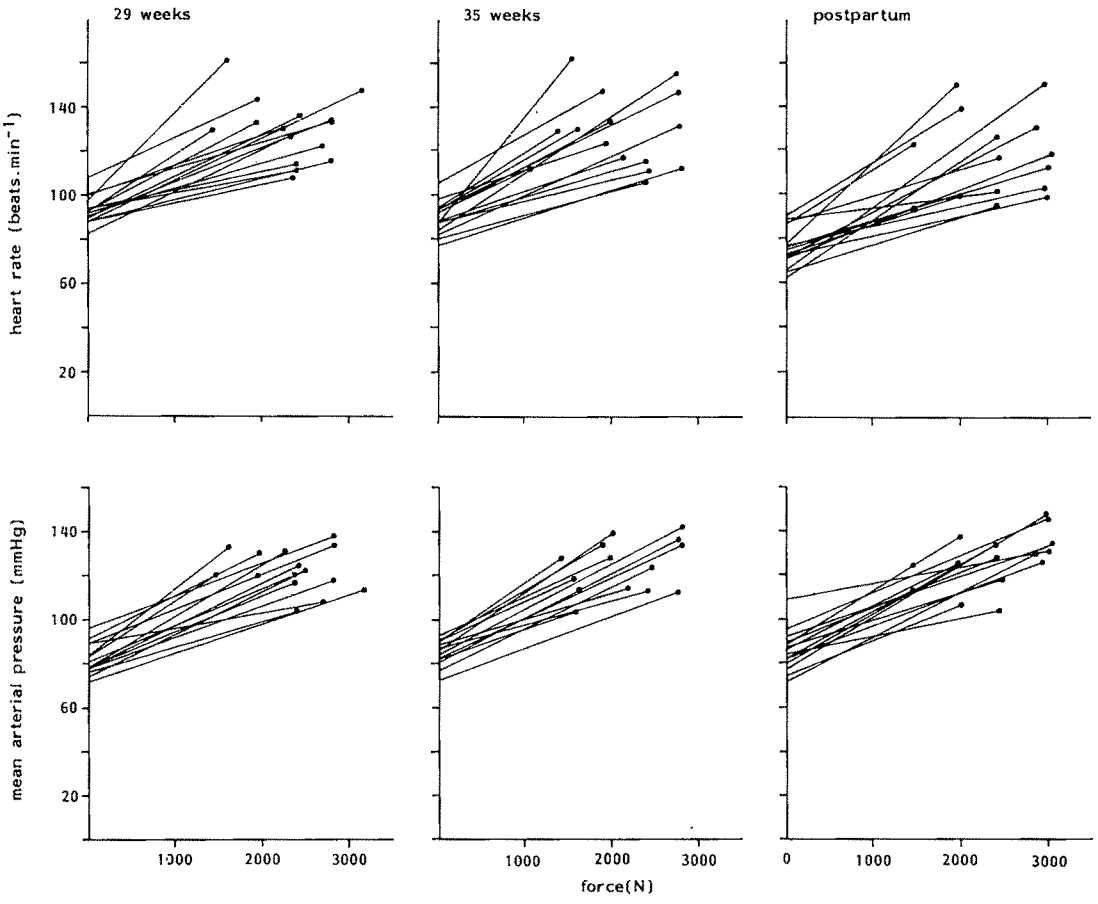

Fig. 1. Individual regression lines representing heart rate and mean arterial pressure responses to increasing levels of isometric exercise at 29 and 35 weeks' gestation and at 8 weeks post partum, $n = 15$.

Comment

The first report on isometric exercise in the obstetric literature concerns a study in which it was proposed that isometric handgrip exercise could serve as a simple and reliable test for the prediction of pregnancy-induced hypertension.[6] That study has been criticized,[10] and in a more recent study no difference in response to handgrip exercise was observed between women with pregnancy-induced hypertension and normotensive women with regard to blood pressure, heart rate, cardiac output, and catecholamine concentrations.[8]

The present study is an effort to study whether pregnancy affects the capability of the body to perform strenuous isometric exercise. We realize that the study has its limitations. First, the study does not have the statistical power to conclude that there is really no difference in pressure response between the pregnant and the postpartum state. However, on the basis of our results a physiologically important difference in response seems unlikely. Second, the postpartum state may not represent the true nonpregnant state. This is true, but in studies in dynamic exercise similar results were obtained at 7 weeks and 6 months post partum. Third, the oscillometric measurement of arterial pressures has not been validated for the use in exercise studies. However, the method has been validated for the observed range of pressures under resting conditions,[9] and we made sure that the volunteers did not use their arm muscles and continued to breathe during isometric leg exercise. Any motion error should have affected pregnant and nonpregnant women alike. We found measurements of maximal force and blood pressures to be reproducible within 10% in three nonpregnant individuals. Fourth, isometric exercise of longer duration may elicit a different response. This point will require further study.

The capability to perform dynamic exercise is unaffected by pregnancy, as both maximal oxygen uptake and maximal power remain the same.[3] The results of the present study indicate that pregnancy does also not affect the capability to perform maximal isometric leg exercise at 29 weeks' gestation. The finding that maximal force was on average 10% lower at 35 weeks than at 29 weeks might be explained by a reduction in the

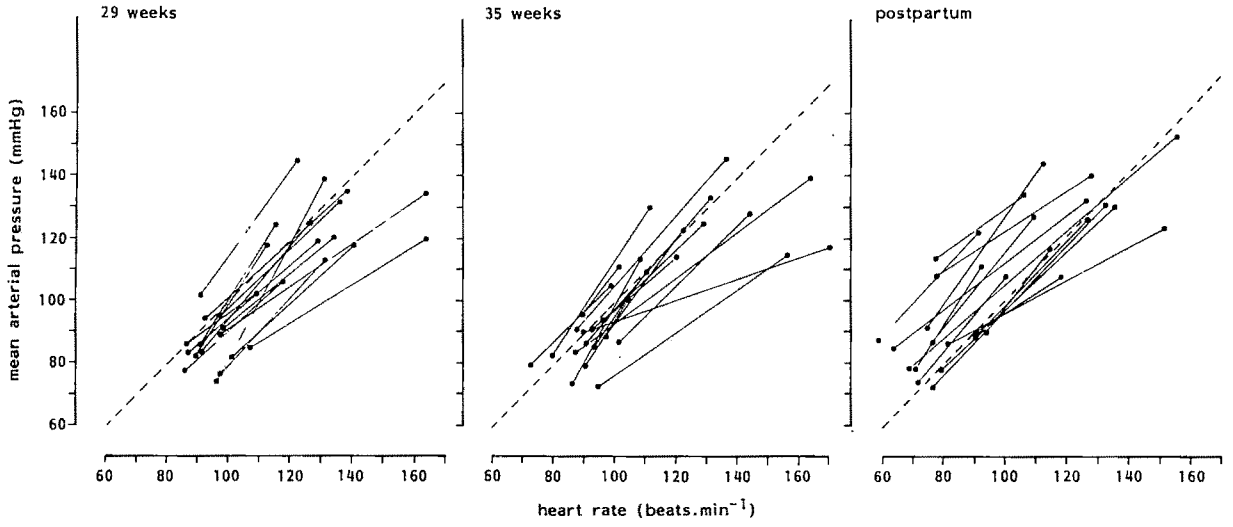

Fig. 2. Individual regression lines representing increase in mean arterial pressure with heart rate during isometric exercise at 29 and 35 weeks' gestation and at 8 weeks post partum, $n = 15$.

supply of oxygen and nutrients to the isometrically exercising muscles, by a decrease in the functional reserve to anaerobic exercise, or by reaching voluntary maximal exercise at an earlier stage. Because the increase in mean arterial pressure with force at 35 weeks' was not significantly different from that in the two other periods, as shown in Fig. 1, the first two possibilities seem unlikely. In dynamic exercise, maximal effort can be determined objectively by the measurement of maximal oxygen uptake,[1] whereas in isometric exercise maximal effort is determined by the subjective feeling of the volunteer. It is conceivable that in some women at 35 weeks' the mechanical discomfort of the protruding abdomen has contributed to reaching a feeling of maximal effort sooner than at 29 weeks' gestation or post partum.

The rise in arterial pressure during isometric exercise may result from an increase in cardiac output, systemic vascular resistance, or both. It is thought that heart rate increases during isometric exercise mainly by central command and vagal withdrawal, whereas blood pressure rises initially by both central command and muscle mechanoreflexes.[5] Later, after approximately 1 minute of exercise, the muscle chemoreflex induces sympathetic nervous activity that affects catecholamine concentrations and systemic vascular resistance.[5] If this concept is true, it seems likely that the increase in blood pressure in our study was caused by increase in cardiac output rather than by a rise in systemic vascular resistance, because periods of exercise were restricted to 45 seconds.

The quotient of mean arterial pressure and heart rate equals the product of stroke volume and systemic vascular resistance. Mean arterial pressure/heart rate is lower at rest at 29 weeks' gestation than it is post partum, as shown in Fig. 2. This is in agreement with the observation that the decrease in systemic vascular resistance during pregnancy is more pronounced than the increase in stroke volume.[11] The constancy of the quotient of mean arterial pressure and heart rate during isometric exercise, as shown in Fig. 2, demonstrates that the blood pressure response is proportional to the increase in heart rate. If the product of stroke volume and systemic vascular resistance during isometric exercise is almost constant and if exercise of short duration does not affect vascular resistance, as was discussed above, stroke volume must also be virtually constant. This would imply that the increase in cardiac output during isometric exercise of short duration is primarily caused by vagal withdrawal through central command, as suggested in the literature.[5]

In spite of altered values of heart rate and arterial pressures at rest, pregnancy does not seem to affect the pressure response to either dynamic[1] or isometric exercise.

We thank Gijsbert de Sterke for his support in data acquisition.

Transvaginal ultrasonographic quantitative assessment of accumulated cul-de-sac fluid

Doron J.D. Rosen, MD, Isaac Ben-Nun, MD, Yael Arbel, MD, Marco M. Altaras, MD, Shmuel B. Goldberger, MD, and Yoram Beyth, MD
Kfar Saba, Israel

Preoperative quantitative assessment of pelvic fluid is an important diagnostic tool in clinical decision making. In this study, we used high-frequency transvaginal ultrasonography in 10 healthy women to assess both the correlation between various amounts of fluid installed in the cul-de-sac and ultrasonic imaging and to determine whether correct estimation of fluid volume can be reached. No fluid could be ultrasonically detected when the volume was <35 to 40 ml. Between 35 and 100 ml there was a clear image of accumulated fluid in the cul-de-sac with good correlation between volume and image, whereas with larger amounts no clear correlation between the amount of fluid introduced and size of fluid area visualized by ultrasonography was possible. Transvaginal ultrasonography may enable quantitative evaluation of certain volumes of pelvic fluid, although amounts <35 ml cannot be visualized. (AM J OBSTET GYNECOL 1992;166:542-4.)

Key words: Cul-de-sac, pelvic fluid, transvaginal ultrasonography

During the past 5 years transvaginal ultrasonography has increasingly gained acceptance in obstetrics and gynecology as a result of its higher resolution. Its use thus provides a more accurate diagnosis of pelvic masses and early detection of extrauterine pregnancies. Although some free fluid is normally present in the female pelvis, especially in midcycle,[1] increased amounts may indicate pathologic conditions, such as bleeding from a tubal pregnancy or a ruptured cyst. Previous reports have indicated that quantitation of free pelvic fluid is possible[2]; however, no direct studies under controlled conditions have been reported. The current study describes the use of transvaginal ultrasonography in quantifying free pelvic fluid volumes.

Patients and methods

Transvaginal ultrasonography with a 6.5 MHz transducer probe (Elscint Ltd., Haifa) was performed on 10 healthy women during diagnostic laparoscopy for infertility. In all women the results of laparoscopy were negative for any pelvic pathologic conditions. After completion of the laparoscopic survey of the pelvic organs, all free pelvic fluid was aspirated with the patients in reverse Trendelenburg position. The patients were then placed in supine lithotomy position, and a plastic 18-gauge Intracath catheter was introduced through the abdominal wall into the cul-de-sac. The carbon

dioxide gas was evacuated from the peritoneal cavity and the laparoscope was then removed. Normal saline solution was introduced into the cul-de-sac through the catheter at increments of 5 to 10 ml, up to a maximum of 150 ml. After each incremental addition, an ultrasonographic image was obtained by directing the beam longitudinally at the midline of the uterus and cul-de-sac, and the image was recorded. At the end of the procedure, the pelvic fluid was reaspirated through the same catheter.

Results

Good-quality images were obtained for all patients. A representative set is shown in Figs. 1 and 2. In all cases fluid up to 30 ml was not seen in the cul-de-sac (Figs. 1 and 2). At 35 to 40 ml a small triangle of fluid, measuring 7 × 7 × 7 mm (± 1 mm), was observed under the most dependent part of the uterus. The size of the triangle increased to 9 × 9 × 10 mm (± 1 mm) when 50 ml was introduced and to 13 × 13 × 15 mm (± 2 mm) when 60 ml was introduced. When 80 ml was

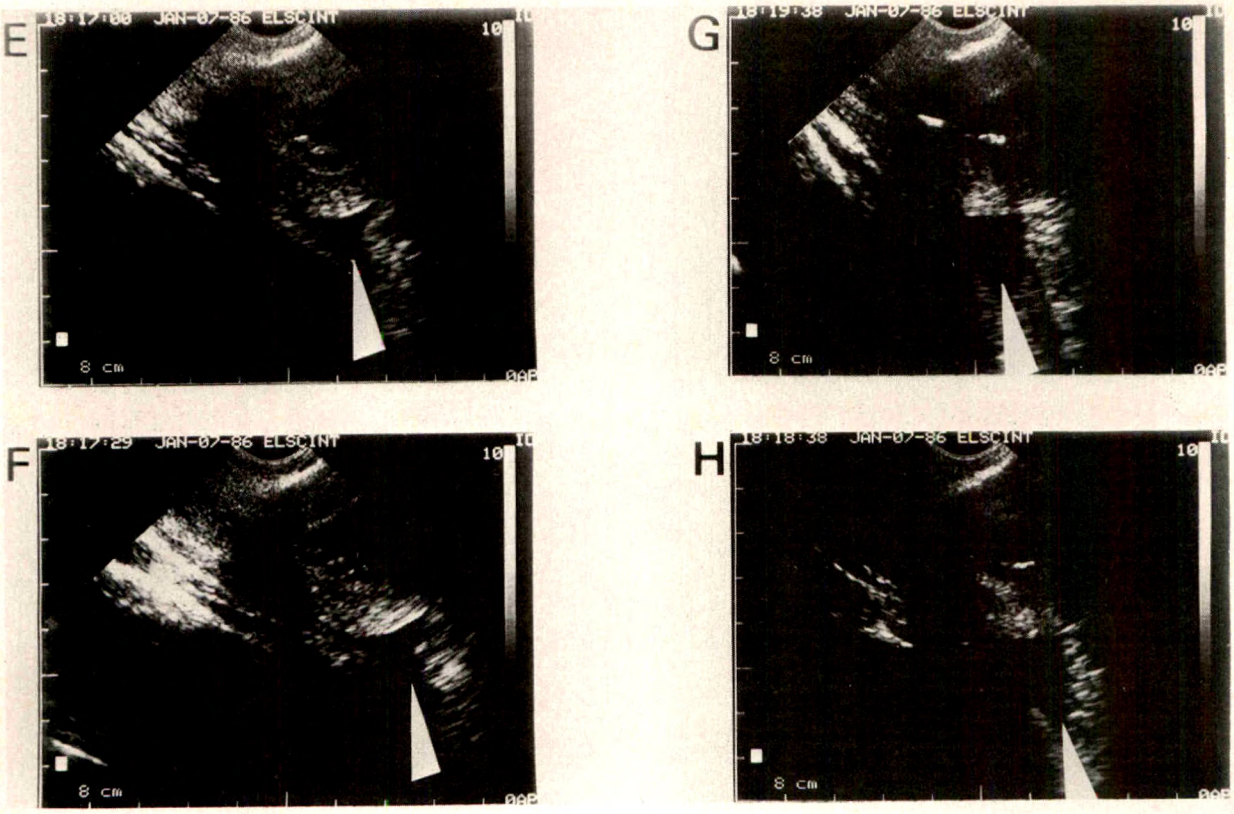

Fig. 1, E to H. Serial images of cul-de-sac with increasing amounts of fluid. **E,** 50 ml; **F,** 60 ml; **G,** 80 ml; **H,** 100 ml.

placed in the pelvis, the triangle enlarged to 20 × 20 × 15 mm (±2 mm). At 90 to 100 ml the fluid-filled area increased substantially and included the nondependent area of the cul-de-sac (Table I). With larger amounts of fluid, no clear delineation of the fluid-filled area was possible; however, increased amounts of fluid were observed. At the conclusion of the procedure, it was possible to aspirate almost all the injected fluid from the cul-de-sac, indicating that all of the fluid was indeed accumulated there.

Comment

Accumulation of fluid in the cul-de-sac may be indicative of a ruptured cyst or ascitic fluid (clear fluid), a ruptured corpus luteum cyst or ectopic pregnancy (blood), pelvic inflammatory disease, or perforated viscous fluid (pus). Because small amounts of fluid can normally be present in the cul-de-sac, it is important for the clinician to be able to correctly assess the amount of fluid. Timor-Tritsch et al.[2] have previously commented on this subject; however, they assessed the presence of fluid in the cul-de-sac during laparotomy, not seeking a correlation between fluid volume and the ultrasonographic image. As shown in this report, our patients were in supine position with closed intact abdominal walls after the removal of the previously introduced gas. All these measures were taken to achieve conditions as similar to normal scanning as possible. Any amount of fluid in the pelvis <35 ml could not be ultrasonographically detected. This is in contrast to the previous report stating that "five ml was easily seen."[2] The reason for this discrepancy is unclear; however, no data were provided in the previous report as to patients' tilt or the scanning plane. At an accumulation between 35 and 100 ml, we found a direct correlation between the size of the fluid area on the ultrasonographic image and the amount of fluid introduced into the pelvis. Accumulation of >100 ml was easily detected, but could not be quantified.

Thus it is possible to correctly assess the amount of pelvic fluid by transvaginal ultrasonography. We have been able to demonstrate this in several cases where transvaginal ultrasonography was performed before diagnostic laparoscopy and aspiration of measured amounts of pelvic fluid (Rosen DJD. Unpublished data).

Comparison of thermal injury zones in loop electrical and laser cervical excisional conization

Michael S. Baggish, MD, Faith Barash, MD, Yvonne Noel, MD, and Marlon Brooks, MD

Syracuse, New York

Thirty cervical conization specimens obtained by thin-loop electric excision were compared with 30 carbon dioxide laser excisional cone specimens. Zones of thermal artifact were measured with a precise stage micrometer technique calibrated to a Zeiss standard. The mean depth of coagulation at the ectocervical margin measured 0.187 and 0.164 mm for thin loop and laser, respectively. Thermal artifact at the endocervical margin was greater with electric loop (0.295 mm) than with superpulsed carbon dioxide laser (0.137 mm). The zones of thermal injury induced by both electric loop and laser made no significant impact on the interpretation of margin adequacy. (Am J Obstet Gynecol 1992;166:545-8.)

Key words: Loop electric conization, carbon dioxide laser, thermal injury

Recent reports of large-loop diathermy to perform outpatient conization for the treatment of cervical intraepithelial neoplasia have appeared in the peer review literature.[1-4] This method of excision combines the advantages of simplicity, hemostasis, and the retrieval of a pathologic specimen with economy. The latter may be exemplified by considering that women who have

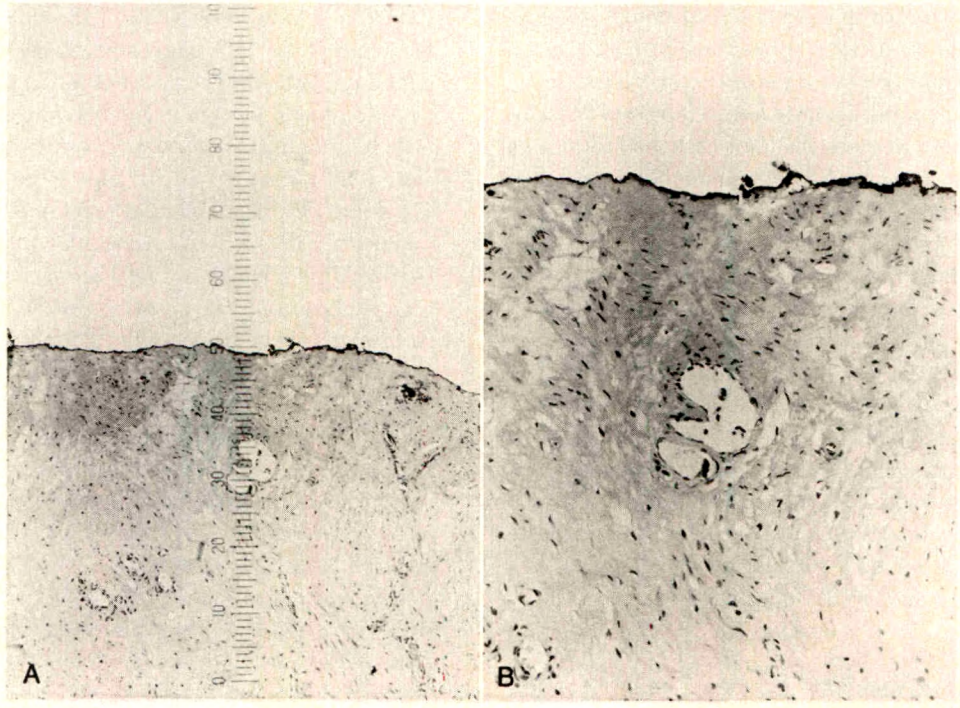

Fig. 1. A, Ectocervical margin of loop electric cone specimen. Stage micrometer is aligned perpendicularly with specimen. (Original magnification ×40.) **B,** Zone of thermal injury can be divided into small zone of carbonization and desiccated-coagulated zone beneath. (Original magnification ×100.)

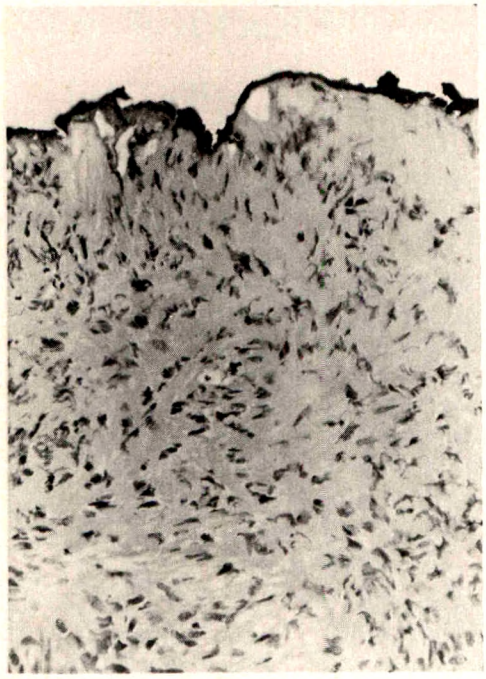

Fig. 2. Total zone of thermal injury measures 0.230 mm. (Original magnification ×200.)

been screened cytologically may undergo a colposcopic examination with accurate identification of the abnormal transformation zone followed by loop electric excisional conization, which provides both histologic diagnosis and therapy in one sitting. Although this therapeutic program at first appears to be ideal, certain concerns should be considered. The histologic quality of the specimen, particularly at the resection margins, is vitally important to determine whether all the disease has been removed and to determine the severity of disease. If thermal artifact makes this determination impossible, then this alone would constitute a major disadvantage of the technique. In the last decade the carbon dioxide laser became an accepted alternative to knife conization because of its precision and hemostatic benefits and because it eliminated the need for sutures. The literature contains descriptions of large numbers of laser conization operations whose specimens showed highly acceptable margins and demonstrated a slight degree of thermal injury to neighboring tissue.[5-7] This article concerns itself with prospectively comparing and accurately quantitating the zones of irreversible thermal injury created by the loop electric cone and the carbon dioxide laser cone.

Material and methods

Thirty loop electric excisional conization specimens were obtained from women with cytologic and colposcopically directed biopsy evidence of cervical intraepithelial neoplasia. Another 30 excisional conization samples emanated from women with cervical intraepithelial neoplasia diagnosed in the outpatient department who underwent laser excisional conization. Both laser and electric loop excisions were performed by M.S.B. or one of the pelvic surgery fellow coauthors. All cone specimens were fixed in formalin, cut, blocked, sectioned, and stained with hematoxylin and eosin.

Table I. Mean depth of thermal injury in excisional conization

Technique	*Ectocervical margin (mm)*	*Endocervical margin (mm)*
Loop electric	0.187	0.295
Carbon dioxide laser	0.164	0.137

The specimens were examined by M.S.B. with an Olympus Vanox T Photomicroscope (Olympus, Newtown, Pa.) equipped with a built-in stage micrometer and floating stage. Before the sections were examined, the stage micrometer was calibrated to a 1 mm standard (Carl Zeiss, Thornwood, N.Y.) subdivided into 0.01 mm segments. The calibration was made with ×4 and ×10 objectives. Margins were measured by orienting the stage to effect a perpendicular measurement, initiating the measurement at the outer carbonized zone and finishing at the beginning of normal stromal or epithelial tissue. Three measurements were performed for each section and averaged. A total of 1200 sections were studied.

An ERBE model 450 (ERBE, USA, Mission Viejo, Calif.) or a Valley Lab Force 2 (Boulder, Colo.) high-frequency (350-750 kHz), low-voltage electrosurgical generator with a 400 W rated output at 350 Ω resistance with automatic voltage regulation during cutting was used for all loop excisions. Five predetermined settings were available with the Erbe unit. The Valley Lab unit was set to deliver 50 W of power. A setting that used a four fifths cut to one fifth coagulation blend was used (setting 200 to 500 V) for the 30 conizations performed with this equipment. The loops used to perform the conizations ranged from 15 to 10 mm in height (measured from the top of the loop to the insulated Y connection of the probe yolk). The wire electrodes measured 0.2 mm in diameter. Conizations were performed by placing the loop perpendicularly to the cervix at either the 12 or 6 o'clock position with approximately a 3 mm margin around the atypical transformation zone, activating the cutting button on the handle of the probe, and allowing the wire to cut into the cervix to the desired depth. Next the loop was swept across the base of the tissue with very slight pressure while the cutting button was depressed, i.e., allowing the speed of the vaporization to determine the velocity of the sweep and subsequent finishing scoop action of the operator's hand.

A Lasersonics model 500 Z (Heraeus Lasersonics, Milpitas, Calif.) carbon dioxide laser rated at 60 W power and equipped with a micromanipulator was cou-

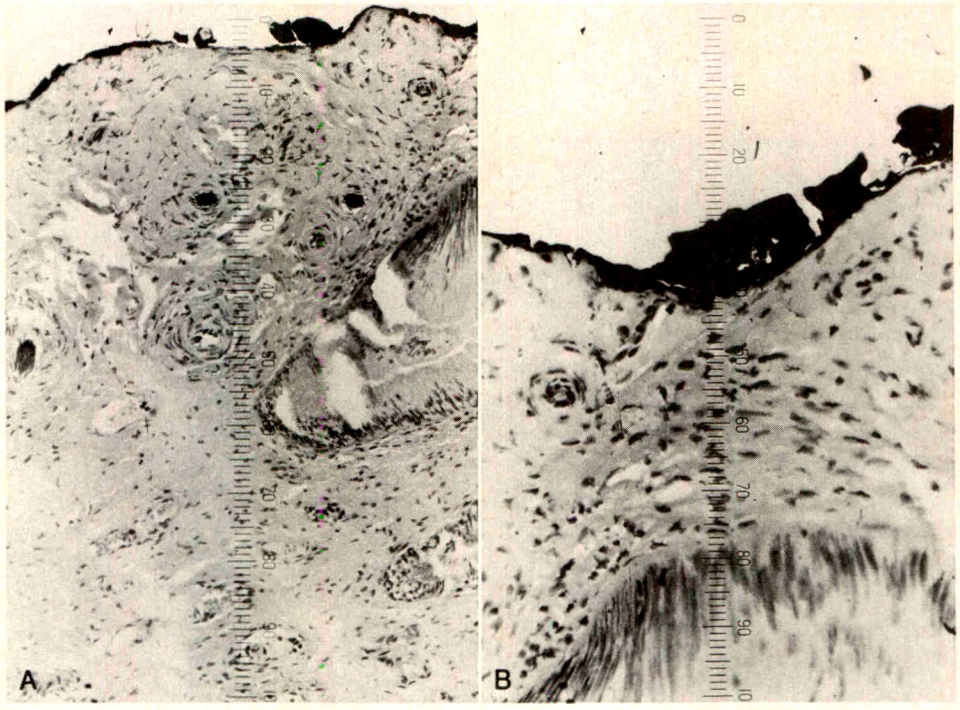

Fig. 3. A, Endocervical margin of loop electric excisional cone shows more extensive zone of thermal injury. Note vascular thrombosis and endocervical cleft distortion. (Original magnification ×100.) **B,** Detail of endocervical margin with 0.390 mm coagulation artifact. (Original magnification ×200.)

pled to a Zeiss OPM 1-H colposcope. The 30 laser conizations were carried out with 40 W of power and a 0.5 mm spot according to methods previously described.[5] The endocervical margin was cut off with a superpulsed beam emitting 500 pulses/sec, 0.5 millisecond pulse width, with an average power of 23 W.

Results

Measurement of sections obtained from loop excisions revealed two zones of thermal injury at the ectocervical and endocervical margins (Table I): (1) a small zone of carbonization and tissue debris (Fig. 1) and (2) a larger zone of coagulation necrosis and vascular coagulation (Fig. 2). The latter could be easily defined from normal stromal tissue by its deeper pink color and its denser appearance (a secondary effect of desiccation). The range of total thermal injury was 0.91 to 0.300 mm with a mean of 0.187 mm.

The thermal injury zone was greater in both range and mean at the endocervical margin (Fig. 3). The range of thermal injury extended from 0.190 to 0.455 mm with a mean thermal injury zone of 0.295 mm.

Laser conization specimens demonstrated identical zones of thermal injury, i.e., carbonized zone and desiccation-coagulation zone. The ectocervical margins total from 0.091 to 0.210 mm with a mean zone of 0.164 mm. The endocervical margin's zone of thermal injury was smaller than those observed with the electric loop, ranging from 0.090 to 0.230 mm with a mean of 0.137 mm (Fig. 4). However, this small difference made no impact on the interpretation or adequacy of the margin.

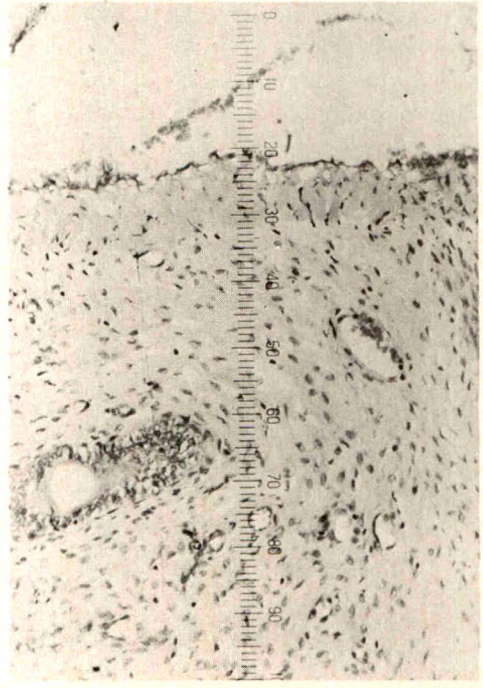

Fig. 4. Superpulsed laser endocervical margin measures 0.143 mm with small carbonization layer. (Original magnification ×100.)

The carbonized zones were virtually identical in both groups, measuring 0.013 to 0.026 mm.

A major difference was noted in specimens taken with the electric loop measuring <5 mm deep. The zone of thermal injury in these instances was extensive, i.e., measuring up to 0.560 mm. The endocervical mucosa particulary showed extensive thermal artifact at the margin of resection. This degree of thermal injury was not produced with superpulsed laser beams, which again showed thermal injury measuring 0.090 mm to 0.230 mm.

Comment

Excisional cones obtained with high-frequency, low-voltage, thin wire loops created wounds that were virtually identical to those obtained with the carbon dioxide laser. The zones of thermal injury were acceptably small and did not interfere with the histopathologic interpretation at either the ectocervical or endocervical margins. From this study the method of tissue ablation appears to be similar with either electric loop or laser modality, i.e., thermal energy creates temperatures exceeding 100° C, resulting in vaporization of tissue. Lesser temperatures resulted in neighboring tissue undergoing desiccation and coagulation with resultant tissue distortion (thermal artifact). At the setting used in this study voltages between 200 and 500 were produced at the interface of the electrode (wire loop) and the tissue, creating electric arcs ideal for vaporization and associated with a low degree of coagulation. When voltage exceeded 500, more extensive coagulation was created with increased thermal artifact. Therefore the narrow band of 200 to 500 V is the acceptable range for electric excisional conization operations.

The laser wounds demonstrated in this study were obtained at power densities of approximately 16,000 W/cm^2. Less thermal damage was obtained at margins where superpulsed beams were used because peak powers were extremely high (250 to 400 W) and pulsing allowed thermal relaxation of the tissues. With higher average superpulse powers, even less thermal injury might be anticipated, and over a large range of power settings, repetition rates, and pulse widths the zone of thermal injury in such instances would clearly vary directly with the duty cycle of the laser so long as that cycle remains <25%.

This study demonstrated that thin-loop high-frequency, low-voltage electric surgery and high–power density carbon dioxide laser produced similar wounds in excised human cervical tissue. The advantages of the electric thin loop relate to its simplicity and speed.

Nematode infections: Is it wise to withhold medical treatment during pregnancy?

I. Biliary complications

Marco A. Villar L., MD, and Baha M. Sibai, MD

Tegucigalpa, Honduras, and Memphis, Tennessee

Appropriate medical treatment should be provided in ascariasis because this benign infection could cause unusual and dangerous complications in pregnancy and may increase maternal-fetal morbidity and mortality. (AM J OBSTET GYNECOL 1992;166:549-50.)

Key words: Nematodes, ascariasis, antiparasitic drugs, gallbladder disease

Ascaris lumbricoides is the most common helminthic infection in humans, with an estimated prevalence of 1 billion infections, with >4 million of these in the United States. Adult worms are known to inhabit the lumen of the small intestine (jejunum and ileum) and have a short life span of approximately 10 to 24 months. Their tropism and, when conditions are unfavorable, migratory tendency toward anatomic orifices make possible the invasion of a majority of organs in the body, resulting in extraintestinal forms of the parasite. Furthermore, this invasion has been considered by others[1] as responsible for coadjuvant illness, such as biliary lithiasis.

Case report

A 24-year-old Hispanic woman, gravida 1, para 0, was evaluated by her obstetrician during the twelfth

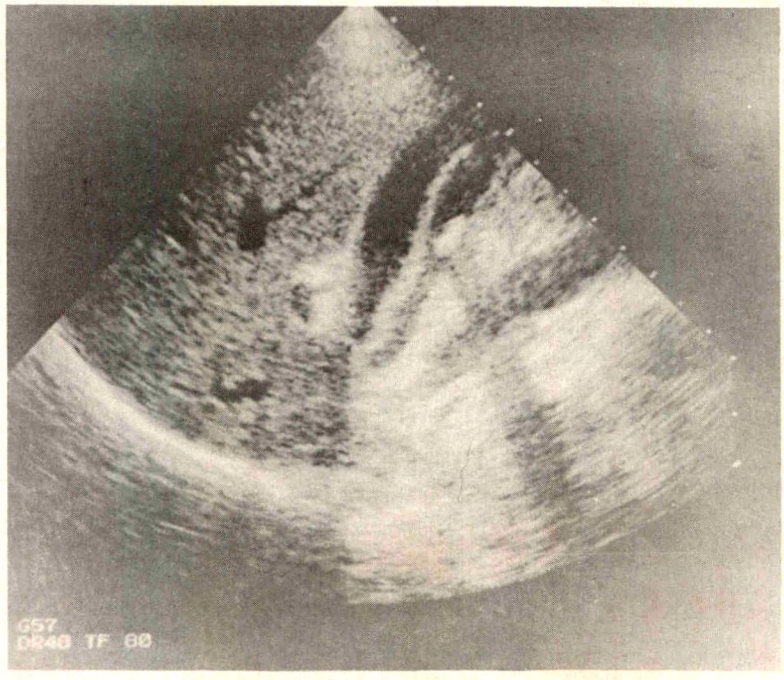

Fig. 1. Sonogram showing adult *A. lumbricoides* worm along with biliary lithiasis in a pregnant patient at 20 weeks of gestation.

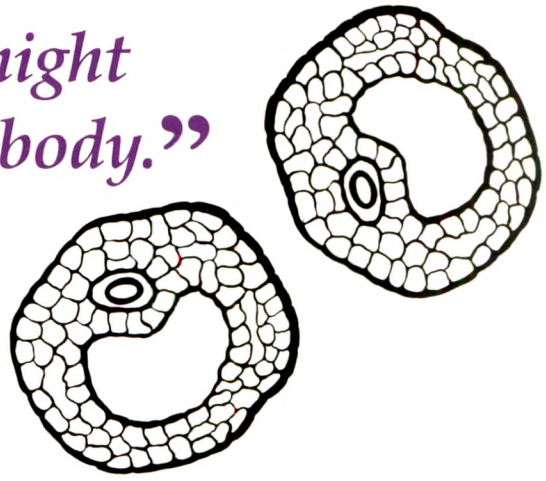
week of gestation. Stool test showed the presence of *A. lumbricoides* eggs. Because of the corollary that "parasitic infections should not be treated during pregnancy," a couple of months later she came to the emergency room complaining of severe upper-right-quadrant pain, nausea, and vomiting. Abdominal ultrasonography revealed the presence of a large adult *A. lumbricoides* worm along with gallbladder stones (Fig. 1), which were obstructing the cystic duct. She was taken to the operating room where, through cholecystectomy, the diagnosis was confirmed. Two more organisms were found after medical treatment with piperazine citrate, 75 mg/kg daily for 2 days. A control stool test showed no further infection. No adverse effects were seen in the healthy male newborn delivered 18 weeks later.

Comment

A number of drugs are effective in the treatment of roundworm infections (ascariasis). Pyrantel pamoate (Antiminth) is highly effective with a single dosage regimen of 11 mg/kg. Piperazine salts (Antepar, Multifuge) are still widely used. Thiabendazole (Mintezol) is generally less effective than pyrantel pamoate or piperazine. The broad-spectrum antihelminthic mebendazol (Vermox) is effective against *A. lumbricoides*, but multiple doses are required (100 mg twice a day for 3 days) to achieve a high cure rate. Treatment failures with this drug have been reported previously. A 3-day regimen of pyrantel pamoate with a single daily dose has been suggested for treatment failure with mebendazol.



Heinonen et al.[2] provided a large sample of pregnant patients in whom piperazine citrate was prescribed. No evidence was found to suggest a relationship with fetal malformations. Experience with mebendazol and pyrantel pamoate in human pregnancies is not available, and recommendation to withhold their use is based on results in animal studies.

In conclusion, ascariasis in pregnancy may not be as benign as expected; therefore these infections should always be treated because they have the potential for causing serious complications in spite of the fact that most patients are asymptomatic. Antiparasitic drugs, such as pyrantel pamoate and piperazine citrate, have not shown adverse effects on the fetus according to our brief experience (unpublished data).

DEMULEN® 1/35

(ethynodiol diacetate 1 mg, ethinyl estradiol 35 mcg)

Where protection begins

The physician should become familiar with the prescribing information (labeling) for this product, which discusses reported risks, such as thromboembolic disorders (including strokes and heart attacks), risk of estrogen dose, and hepatic lesions, as well as the need to monitor patients for early symptoms of any diseases or medical conditions, so use can be discontinued when appropriate.

Please see adjoining page for a brief summary of prescribing information.

The OC innovator SEARLE

DEMULEN® 1/35

(ethynodiol diacetate 1 mg, ethinyl estradiol 35 mcg)

Where protection begins

BRIEF SUMMARY

Demulen® 1/35: Each white tablet contains ethynodiol diacetate 1 mg and ethinyl estradiol 35 mcg. Each blue tablet in Demulen 1/35-28 is a placebo containing inert ingredients. **Demulen® 1/50:** Each white tablet contains ethynodiol diacetate 1 mg and ethinyl estradiol 50 mcg. Each pink tablet in Demulen 1/50-28 is a placebo containing inert ingredients.

Indication and usage: For prevention of pregnancy. Pregnancy rate for products with ≥35 mcg ethinyl estradiol or ≥50 mcg mestranol is ≤1/100 woman-years. With ≤35 mcg ethinyl estradiol, rate is slightly higher; with progestogen-only oral contraceptives (OCs), rate is about 3. Precise comparisons cannot be made. Rates for other methods have been published. *Dose-related Thromboembolic Risk.* Studies showed positive association between OC estrogen dose and thromboembolic risk. It is in keeping with good therapeutics to minimize estrogen exposure. Prescribe product containing least amount of estrogen compatible with acceptable pregnancy rate and patient acceptance. Start new users on ≤50 mcg estrogen.

Contraindications: Thrombophlebitis, thromboembolic disorders, past history of deep vein thrombophlebitis or thromboembolic disorders; cerebrovascular disease, myocardial infarction or coronary artery disease, or past history of these; known or suspected breast carcinoma, estrogen-dependent neoplasia, or pregnancy; undiagnosed abnormal genital bleeding; past or present, benign or malignant liver tumors developing during use of estrogenic products.

Warnings:

Cigarette-smoking increases risk of serious cardiovascular side effects from OC use. Risk increases with age and heavy smoking (15 or more cigarettes/day) and is quite marked in women over 35. OC users should be strongly advised not to smoke. OCs are associated with increased risk of several serious conditions including venous and arterial thromboembolism, thrombotic and hemorrhagic stroke, myocardial infarction, visual disorders, hepatic tumors, gallbladder disease, hypertension, fetal abnormalities. Practitioners should be familiar with the available information relating to these and other risks.

1. *Thromboembolic disorders and other vascular problems:* Increased risk of thromboembolic and thrombotic disease associated with OCs is well established. A British study showed increased risk for fatal venous thromboembolism (TE); British and U.S. studies showed increased risk for nonfatal disease. U.S. studies showed increased risk for stroke. OC users were 2-11 times more likely to manifest these diseases without evident cause. In a study of idiopathic deep vein thrombosis and pulmonary embolism (PE), projected hospitalization rates for ages 16-40 were 47/year/100,000 users and 5 for nonusers. Overall excess mortality from PE or stroke was 1.3-3.4 deaths/year/100,000 users and increased with age. *Cerebrovascular Disorders:* In a study of stroke with and without predispositions, risk of hemorrhagic stroke was 2 times greater and thrombotic stroke 4.0-9.5 times greater in users. Mortality trends in 21 countries indicate that changes in cardiovascular mortality were associated with changes in OC prevalence. The Royal College of GPs (RCGP) reported on its prospective study: "A statistically significant higher rate of reporting of cerebrovascular accidents in Takers is evident, but the numbers are too small to justify an estimation of the degree of risk." A 1981 analysis showed a 4-fold increased mortality in users from circulatory diseases, mainly myocardial infarction (MI) and hemorrhagic stroke. Excess mortality was associated with age and smoking. A 1983 analysis showed elevated cerebrovascular disease, increasing with use to 8 yrs, including cerebral thrombosis or embolism and TIA. Peripheral arterial disease and MI were increased. Women over 30 had more arterial disease, being greatest in smokers. Arterial case-fatality was 2-3 times greater for users who smoked. Family Planning Assoc. (FPA) found significant association between OC use and stroke, increased risk for venous thrombosis and PE was 4-fold and statistically significant. Mortality from nonrheumatic heart disease was greater in ever-users. In the Walnut Creek Study, subarachnoid hemorrhage risk was associated with smoking, age, and OC use. *Myocardial Infarction:* Increased risk of MI associated with OCs was reported in Britain, as previously suspected. The morbidity study found the greater the number of risk factors for coronary artery disease (smoking, hypertension, hypercholesterolemia, obesity, diabetes, history of preeclamptic toxemia) the higher the risk, regardless of OC use. OCs were an additional risk factor. Excess rate of fatal MI was 3.5/year/100,000 users aged 30-39 and 20 for ages 40-44. (These are based on British statistics with acute MI death rates 2-3 times less than the U.S. Similar estimates for the U.S. are 25.7 for users aged 30-39 with predispositions vs 1.5 without; for ages 40-44, 86.2 vs 5.1.) Excess hospitalization rate for nonfatal MI in Britain was 3.5/year/100,000 users aged 30-39 and 47 for ages 40-44. Smoking is a major predisposing condition to MI. In terms of relative risk, nonsmoking OC users are twice as likely to have fatal MI as nonsmoking nonusers. Smoking users have a 5-fold greater risk than nonsmoking users, but a 10-12-fold greater risk than nonsmoking nonusers. Amount of smoking is an important factor. In determining importance of these risks, give serious consideration to rates in table below. Importance of other predispositions cited above in determining relative and absolute risks has not been quantified; it is likely the same synergism exists, but perhaps to a lesser extent. U.S. studies similarly relate MI, OCs, smoking, and age.

Estimated Mortality Rate from Myocardial Infarction per 100,000 Women-Year

	Aged 30-39	*Users*	*Nonusers*	*Aged 40-44*	*Users*	*Nonusers*
All smokers		10.2	2.6		62.0	15.9
≥15 cigarettes daily		13.0	5.1		78.7	31.3
<15 cigarettes daily		4.7	0.9		28.6	5.7
Nonsmokers		1.8	1.2		10.7	7.4
Smokers and nonsmokers		5.4	1.9		32.8	11.7

Risk of Dose: Reports of TE after use of OCs with ≥50 mcg estrogen received by drug safety committees in Britain, Sweden, and Denmark were compared with distribution expected from market research sales estimates. A positive correlation was found between estrogen dose and reporting of TE, including coronary thrombosis, in excess of that predicted by sales. OCs with ≥100 mcg estrogen were associated with higher TE risk than those with 50-80 mcg. Estrogen quantity may not be the sole factor; influence of progestogens was not considered, which may be responsible for certain discrepancies in the data. No significant differences were noted between OCs containing same estrogen dose nor between ethinyl estradiol and mestranol. In Britain certain TE conditions were associated with progestogen or estrogen dose. In Sweden reports of TE decreased when higher estrogen doses were no longer prescribed. Studies on TE risk with progestogen-only OCs have not been done. Cases have been reported for these; they are not presumed free of risk. In a U.S. case-controlled study, relative risk of OC use 1 month before hospitalization for various types of TE was calculated. If relative estrogenic potency and possible influence of different progestogens are ignored, OCs may be divided into those with <100 mcg and those with ≥100 mcg estrogen. For all cases combined, larger doses were associated with only slightly higher risk; for idiopathic cases risk was doubled with larger doses, but confidence limits overlapped and differences were not significant. Apparently there was less increased risk for cases with predispositions. In FPA study no nonhemorrhagic strokes occurred with <50 mcg estrogen, vs 13 with higher doses. Latter group also had more venous TE. TE risk in users and nonusers increases with age. OCs have been considered an independent risk factor. Decreased HDL, which relates to increased myocardial ischemia, occurs with high progestational activity. Consider amount of both steroids in choosing OC. *Persistence of Risk after OC discontinuation was reported for* circulatory disease, nonrheumatic heart disease, and cerebrovascular disease, including subarachnoid hemorrhage, cerebral thrombosis, and TIA. *Excess Mortality from Circulatory Diseases:* A U.K. prospective study estimated annual mortality from circulatory diseases for OC users and nonusers by age, smoking, and duration of use. Excess mortality was 23/100,000 users (2 and 10 for ages 25-34, 15 and 48 for ages 35-44, 41 and 179 for ages >44, for nonsmokers and smokers, respectively). Risk was significant only for smokers over 34. Most deaths were due to subarachnoid hemorrhage or ischemic heart disease. Risk for ever-users rose with parity. One study estimated risk of death with various contraceptive methods, each estimate including risk of method (eg, TE for OCs) plus risk due to pregnancy or abortion in cases of method failure. This latter risk varies with effectiveness. It concluded mortality with all methods is low and below that of childbirth, except for OC users over 40 who smoke. Heavy smokers have double the risk of smokers, light smokers about half. Mortality with OC use in nonsmokers over 40 is higher than with any other method in that age group. Lowest mortality is with condom or diaphragm backed up by early abortion. Risk of TE and thrombotic disease with OCs increases with age after 30 and, for MI, is further increased by hypertension, hypercholesterolemia, obesity, diabetes, history of preeclamptic toxemia, and especially cigarette smoking. Based on current data, the chart gives gross estimates of risk of death from circulatory disorders associated with OCs.

Risk is: A—very high; B—high; C—moderate; D—low. Age	<30	30-39	≥40
Heavy smokers (≥15/day)	C	B	A
Light smokers (<15/day)	D	C	B
Nonsmokers, no predispositions	D	C,D	C
Nonsmokers, with predispositions	C	C,B	B,A

Be alert to earliest manifestations of TE disorders (eg, thrombophlebitis, PE, cerebrovascular insufficiency, coronary artery disease, MI, retinal thrombosis, mesenteric thrombosis). Should any be suspected, discontinue OCs immediately. A 4-7-fold increased risk of postsurgery TE was reported in users; if feasible discontinue OCs at least 4 weeks before surgery or in prolonged immobilization. Before resuming OCs, weigh risks of postsurgery TE complications against contraceptive needs. RCGP reported higher incidence of superficial and deep vein thrombosis in users, the former correlated with progestogen dose. Varicose veins have little effect on development of deep vein thrombosis. **2.** *Ocular lesions:* Neuro-ocular lesions such as optic neuritis or retinal thrombosis have been associated with OCs. Discontinue if there is unexplained, gradual or sudden, partial or complete loss of vision; proptosis or diplopia; papilledema; or evidence of retinal vascular lesions. Institute diagnostic and therapeutic measures. **3.** *Carcinoma:* Long-term estrogen in certain animals increases carcinomas and/or nonmalignant neoplasms, such as those of breast, uterus, cervix, vagina, ovary, liver, pituitary. Some synthetic progestogens, none currently in OCs, increase incidence of benign and malignant mammary nodules in dogs. Estrogens increase risk of human endometrial carcinoma. In case-controlled studies, increased risk (2.2-13.9 times) associated endometrial carcinoma with prolonged estrogen for menopausal symptoms. Risk was independent of other known risk factors and depended on duration of use and dose. This is supported by increased endometrial cancer incidence since 1969 in areas with cancer-reporting systems, which may be related to expanding estrogen use. There is no evidence that natural estrogens are more or less hazardous than synthetics. Of the first 30 cases of endometrial carcinoma in OC users under 40, those without predispositions occurred nearly always with no-longer-marketed sequential OCs. No statistical association is reported suggesting increased endometrial cancer with combination or progestogen-only OCs. Studies show no increased breast cancer with OCs or estrogens. However greater risk was noted in OC users with benign breast disease or long-term (2-4 years) use. One study found greater risk of breast cancer with >4 years OC use prior to first full-term pregnancy. Risk of breast cancer with menopausal estrogens rose and further increased with duration of follow-up. OCs or estrogen were related to breast cancer in connection with other risk factors and in various subgroups. Decrease in benign breast tumors in OC users is well known. Some studies suggested increased risk of cervical dysplasia. CIN, erosion, and carcinoma in long-term users. Cervical microglandular hyperplasia has been reported. In summary, there is no consistent evidence from human studies of increased cancer risk with OCs. Close surveillance is, however, essential. In undiagnosed persistent or recurrent abnormal vaginal bleeding, consider nonfunctional causes and take diagnostic measures to rule out malignancy. Carefully monitor users with strong family history of breast cancer or with breast nodules, fibrocystic disease, recurrent cystic mastitis, abnormal mammograms, or cervical dysplasia. **4.** *Hepatic adenomas, etc.* have been associated with OCs. In 1 study OC formulations with high "hormonal potency" were associated with higher risk, as was age over 30. Though benign, these lesions may rupture and cause fatal hemoperitoneum in short- or long-term users. Two studies related risk to duration of use, being much greater after ≥4 years. Long-term OC users have an estimated adenoma incidence of 3-4/year/100,000. Consider such lesions in users with abdominal pain, tenderness, mass, or shock. About 25% present with abdominal masses, up to half with acute hemoperitoneum. Radiologic and lab studies may not be helpful; liver scans may show local defect. Hepatic arteriography or CAT may be useful. Hepatocellular carcinoma risk is increased 7-20 times in users for 8 or more years. Bile duct cancer may occur with OC use. **5.** *Use in or immediately preceding pregnancy; birth defects; malignancy in offspring:* Estrogens or progestogens during early pregnancy may seriously damage offspring. Females exposed in utero to DES and other nonsteroidal estrogens may have increased risk of vaginal or cervical cancer. Though OCs may not enhance this risk, monitor such patients carefully. From 30-90% of DES-exposed women develop benign vaginal or cervical adenosis, which could be premalignant. DES-exposed daughters have more unfavorable pregnancy outcomes. Males so exposed may develop urogenital and sperm defects. Other estrogens may mimic DES. Reports relate fetal exposure to female sex hormones and congenital anomalies, eg, VACTERL for vertebral, anal, cardiac, tracheoesophageal, renal, and limb defects. There appears preferential expression by males. There was a 4.7-fold increased risk of limb-reduction defects in infants exposed in utero to sex hormones (OCs, hormonal withdrawal pregnancy tests, or treatment for threatened abortion). Some exposures were very short, being only a few days. Cardiovascular defects in children exposed to female hormones, including OCs, during early pregnancy occurred in 18.2/1,000 births compared to 7.8 for those unexposed (P<.05). Female hormone exposure in utero was associated with testicular and ovarian cancer. More twinning was reported in conceptions shortly after OC discontinuance. Female sex hormones were used for threatened or habitual abortion, but there is considerable evidence estrogens are ineffective and no evidence progestogens are effective. Triploidy and possibly other polyploidy may be increased in abortuses from women becoming pregnant soon post-OC. These almost always abort spontaneously. It is unknown if spontaneous abortion is increased soon after stopping OCs. Increased chromosome aberrations have been reported. Safety of OCs in pregnancy has not been demonstrated. Rule out pregnancy in using OCs and always consider it if withdrawal bleeding does not occur. If 2 consecutive periods are missed, rule out pregnancy before continuing. If user deviates from regimen, consider pregnancy at first missed period and withhold OCs. If pregnancy is confirmed, stop OC and apprise patient of potential fetal risks and discuss continuation of pregnancy. Users discontinuing for pregnancy should use alternative contraception for 3 months before attempting to conceive, though this is not based on precise information. Do not use progestogen-only or progestogen-estrogen drugs as pregnancy tests. **6.** *Gallbladder disease* risk, surgically confirmed, appeared after 2 years' use and doubled after 4-5 years in 1 study; it appeared in 6-12 months' use in another. Bile duct cancer has been reported. **7.** *Carbohydrate and lipid metabolism:* Decreased glucose tolerance occurs in a significant number of users; carefully observe diabetic and prediabetic patients. Triglycerides, total phospholipids, and lipoproteins may increase. **8.** *Elevated blood pressure* (BP) occurs in some users in a few months, and degree may relate to progestogen dose. Hypertension prevalence in users is not higher in the first year, but increases with longer exposure; in the 5th year it is 2½–3 times the first year. Age is strongly correlated with hypertension in users. Those with history of elevated BP (hypertension), preexisting renal disease, history of toxemia or elevated BP in pregnancy, familial tendency to hypertension or its consequences, or history of excessive weight gain or fluid retention during menstrual cycles may be more likely to develop elevated BP on OCs and should be monitored closely. Even though elevated BP may be in "normal" range, do not ignore implications. Follow closely, particularly those with other risk factors for cardiovascular disease or stroke. High BP may or may not persist after stopping OCs. **9.** *Headache:* Onset or exacerbation of migraine or development of headache of a new pattern that is recurrent, persistent, or severe requires stopping OCs and evaluating cause. **10.** *Bleeding irregularities:* Breakthrough bleeding (BTB), spotting, and amenorrhea are frequent reasons for discontinuing. In BTB, as in all cases of irregular bleeding, consider nonfunctional causes. In undiagnosed persistent or recurrent bleeding, rule out pregnancy or malignancy. If pathology is excluded, time or change to another product may suffice. Change to a higher-estrogen OC only when necessary as this may increase thromboembolic risk. Those with history of oligomenorrhea or secondary amenorrhea or without established regular cycles may be anovulatory or amenorrheic after discontinuing. Those with such problems should be so informed and other methods encouraged. Post-use anovulation, possibly prolonged, may occur in women without previous irregularities. Higher incidence of galactorrhea and of pituitary tumors has been associated with postpill amenorrhea. One study reported 16-fold increased prevalence of pituitary prolactin-secreting tumors in patients with postpill amenorrhea when galactorrhea was present. **11.** *Ectopics:* In failures with combination OCs, the ratio of ectopic to intrauterine pregnancies is no higher than in nonusers. **12.** *Breast feeding:* OCs may decrease quantity and quality of milk. A small fraction of OC steroids appears in milk. Effects if any on child are unknown. If feasible defer OCs until after weaning. **13.** *Infertility* may occur after discontinuing OCs. While impairment diminishes with time, there is still an appreciable difference in nulliparas aged 25-29 after 30 months; difference is negligible after 48 months. In nullips aged 30-34 impairment persists to 72 months and is more severe for 2-year users. In paras aged 25-34, difference is negligible after 30 months. **Precautions:** Conduct complete history and physical prior to OC use and annually thereafter. Include breasts, abdomen, and pelvis, with BP, Pap, and lab tests. Preexisting uterine leiomyomata may enlarge. Mental depression may occur; with positive history, observe carefully and discontinue if serious recurrence. Fluid retention may occur; prescribe cautiously and monitor carefully in convulsive disorders, migraine, asthma, or cardiac, hepatic, or renal dysfunction. History of jaundice in pregnancy increases risk of recurrence on OCs; observe carefully and discontinue if it occurs. Cholestatic jaundice occurred after OC and troleandomycin use. OC/cyclosporine combination may be hepatotoxic. Steroids may be poorly metabolized in liver dysfunction and should be given cautiously. Tryptophan metabolism may be disturbed and result in pyridoxine deficiency; megaloblastic anemia has been reported. Serum folate may be depressed and may be exacerbated in post-OC pregnancy. Advise pathologist of OC use when submitting specimens. Endocrine and liver function tests may be altered; repeat abnormal tests after stopping for 2 months. These have been observed: increased BSP retention and other abnormalities in liver function tests; increased prothrombin and coagulation factors VII, VIII, IX, X; decreased antithrombin III; increased platelet aggregability; increased thyroid-binding globulin leading to increased circulating total thyroid hormone (PBI, T^4); decreased T^3 uptake; unaltered free T^4; decreased pregnanediol excretion; reduced metyrapone response; increased blood transcortin, corticosteroid, triglyceride, phospholipid, reduced serum folate; impaired glucose tolerance; altered plasma trace minerals. Influence of prolonged OC use on pituitary, ovarian, adrenal, hepatic, or uterine function, or on immune response not established. OCs may mask onset of climacteric. Cervical chlamydial and gonorrheal prevalence is increased; do not assume OC protects against chlamydial PID. HIV seropositivity was associated with OC use. *Information for patients.* See patient labeling. *Drug interactions.* OC effectiveness may be decreased and more BTB occur with rifampin, isoniazid, ampicillin, neomycin, penicillin V, tetracycline, chloramphenicol, sulfonamides, nitrofurantoin, griseofulvin, barbiturates, phenytoin, carbamazepine, primidone, phenylbutazone, analgesics, tranquilizers, antimigraines. OCs may alter effectiveness of oral anticoagulants, anticonvulsants, tranquilizers, tricyclic antidepressants, antihypertensives, theophylline, caffeine, vitamins, hypoglycemics, clofibrate, glucocorticoids, acetaminophen. **Adverse reactions:** Increased risk of the following serious adverse reactions has been associated with OCs: thrombophlebitis and thrombosis; pulmonary embolism; arterial thromboembolism; Raynaud's disease; myocardial infarction; coronary thrombosis; cerebral thrombosis; cerebral hemorrhage; hypertension; gallbladder disease. Budd-Chiari syndrome; benign adenomas and other hepatic lesions, with or without intra-abdominal bleeding; liver cancer; congenital abnormalities. There is evidence of association between the following and OCs, though confirmatory studies have not been done: mesenteric thrombosis; neuro-ocular lesions, eg, retinal thrombosis and optic neuritis. The following are believed drug related: nausea, vomiting, gastrointestinal symptoms; BTB, spotting; change in menstrual flow; dysmenorrhea; amenorrhea during and after use; infertility post-OC; edema; chloasma or melasma, which may persist post-OC; breast changes (tenderness, enlargement, secretion); weight changes; change in cervical erosion and secretion; endocervical hyperplasia; lactation decrease; cholestatic jaundice; migraine; enlarged uterine leiomyomata; allergic rash; mental depression; reduced carbohydrate tolerance; vaginal candidiasis; change in corneal curvature (steepening); intolerance to contact lenses. Association not confirmed or refuted for: premenstrual-like syndrome, cataracts; libido changes; chorea; appetite changes; cystitis-like syndrome; headache; paresthesia; nervousness; dizziness; auditory disturbances; rhinitis; fatigue; backache; hirsutism; scalp hair loss; erythema multiforme or nodosum; hemorrhagic eruption; herpes gestationis; hidradenitis suppurativa; hemolytic uremia; malignant hypertension; impaired renal function; acute renal failure, sometimes irreversible; itching; vaginitis; porphyria; PVCs; abnormal EKG; pulmonary hypertension; TTP; anemia; pancreatitis; hepatitis; colitis; Crohn's disease; gingivitis; dry socket; lupus erythematosus; rheumatoid arthritis; pituitary tumors (eg, adenoma) with amenorrhea and/or galactorrhea after use; malignant melanoma; endometrial, cervical, breast, and bile duct carcinoma. **Acute overdosage:** Serious ill effects have not been reported after large acute doses of OCs in young children. Nausea and withdrawal bleeding might occur. **Important note: Complete prescribing information should be consulted prior to use and is available on request.**

Composite assessment of gestational age: A comparison of institutionally derived and published regression equations

Lyndon M. Hill, MD,[a] David Guzick, MD,[b] Joyce Hixson, RDMS,[a] Carol S. Peterson, RDMS,[a] and Dawn M. Rivello, RDMS[a]

Pittsburgh, Pennsylvania

OBJECTIVES: This study was undertaken to evaluate (1) the applicability of previously reported regression equations for gestational age assessment to our patient population in Pittsburgh and (2) whether the addition of radius length or its substitution for one of the other fetal measurements could improve the prediction of gestational age.

STUDY DESIGN: Five fetal parameters—biparietal diameter, head circumference, abdominal circumference, femur length, and radius length—were measured in a prospective cross-sectional study of gestational age assessment in 265 pregnant women between 13 and 43 weeks' gestation.

RESULTS: The regression equation derived for each fetal parameter was found to be quite similar to previously published reports. Although the coefficient of determination was only minimally affected, the variability improved with the institutionally derived regression equation.

CONCLUSION: The incorporation of several fetal measurements into a composite assessment of gestational age generally enhances the accuracy of the prediction. The addition of a second long bone to a gestational age assessment does not significantly improve results. (Am J Obstet Gynecol 1992;166: 551-5.)

Key words: Estimation of gestational age, multiple fetal growth parameters

The biparietal diameter was one of the first fetal parameters used to assess gestational age.[1] To this day, it remains the standard against which all other fetal biometric data for predicting gestational age are compared.[2-5] In general, the confidence intervals for any fetal measurement increase with advancing gestation. With respect to the biparietal diameter, for example, the maximum variability exceeds 3.0 weeks during the last month of pregnancy.[6] Hadlock et al.[7] sought to improve the estimation of gestational age in the third trimester by combining the data from two or more of the following fetal measurements: biparietal diameter, head circumference, abdominal circumference, and femur length. A simple averaging technique was used in which equal weight was given to each parameter measured. For example, when all four parameters were used, the individual estimates of gestational age on the basis of each parameter were added and then divided by four to obtain a composite assessment of gestational age. This method not only improved the correlation coefficient with gestational age but also reduced maximum variability. In a subsequent study by Hadlock et al.,[8] multivariate regression was used to determine the independent contribution of each of these fetal biometric parameters to the determination of gestational age. Although the multivariate regressions provided better estimates (i.e., reduced variability) than univariate regressions, the results were not significantly different from those obtained with a simple averaging technique.[8]

The current study represents an extension of the work by Hadlock et al.,[8] stemming from two considerations. First, it is possible that, although statistical predictions of gestational age may be quite accurate for the population from which they are derived, they may not be reliably applied to a patient group from a different geographic region or institutional setting. Thus one goal of the present study is to assess the applicability of the regression equations derived by Hadlock et al.[8] from their Houston data to our patient population at Magee-Womens Hospital in Pittsburgh. Second, when Hadlock et al.[8] published their work on the composite assessment of gestational age, they evaluated the four fetal parameters most commonly measured at that time. Several additional fetal measurements are now available. For example, we have recently assessed radius length as a predictor of gestational age.[9] A second goal of the study is to determine if the addition of radius length, or its substitution for one of the standard fetal measurements mentioned above, could improve the prediction of gestational age.

Material and methods

The study group consisted of 265 consecutive women who were delivered at Magee-Womens Hospital, Pitts-

BPD, AC, FL	$GA = 10.61 + 0.175(BDP)\,(FL) + 0.2970(AC) + 0.7100(FL)$	1.06	0.88
HC, AC, FL	$GA = 11.38 + 0.070(HC)\,(FL) + 0.9800(BPD)$	1.04	0.86
HC, AC, FL	$GA = 10.33 + 0.031(HC)\,(FL) + 0.3610(HC) + 0.0298(AC)\,(FL)$	1.03	0.85
HC, AC, BPD	$GA = 10.58 + 0.005(HC)^2 + 0.3635(AC) + 0.02864(BPD)\,(AC)$	1.14	1.09
BPD, HC, AC, FL	$GA = 10.85 + 0.060(HC)\,(FL) + 0.6700(BPD) + 0.1680(AC)$	1.02	0.86

BPD, Biparietal diameter; *GA,* gestational age; *HC,* head circumference; *AC,* abdominal circumference; *FL,* femur length.

burgh, and fulfilled the following criteria: (1) regular menses before conception, (2) an accurate date of the last menstrual period, (3) a positive pregnancy test result by 7 weeks' gestation, and (4) a pelvic examination to assess uterine size by 8 weeks' gestation. Patients with diseases known to affect fetal growth (e.g., diabetes mellitus) were excluded. Patients with multiple gestations were not accepted into the study group. The gestational ages of the study population ranged from 13 to 43 weeks. All the neonates weighed between the 10th and 90th percentiles at delivery.[10]

Each ultrasonographic examination was performed with commercially available real-time linear array ultrasonography equipment with either a 3.5 or 5.0 MHz transducer (General Electric, RT 3000 and RT 3200). Standard techniques were used for measurement of biparietal diameter,[6] head circumference,[11] abdominal circumference,[2] femur length,[3] and radius.[9] Electronic calipers set at a speed of sound in tissue of 1540 m/sec were used for linear measurements. The abdominal and head circumference were obtained directly from the ultrasonography unit after a tracing was made around the image on the screen with a track ball.

The robustness of the regression methods used by Hadlock et al.[8] to analyze their Houston data was assessed in two ways. First, the estimated parameters from the Houston equations were applied to our Pittsburgh data to generate predicted gestational ages. These predicted values were then compared with the actual gestational ages to assess an error of prediction, defined as the standard deviation of the residual values. Second, the functional forms of the Houston equations were used to reestimate the regressions with Pittsburgh data. The standard deviations of the resulting regression equations were then compared with those reported from Houston.

The assessment of whether radius length improves the prediction of gestational age was determined by running regressions with and without radius length. The statistical significance of regression coefficients for radius length was taken to reflect an independent, incrementally important, predictive role. Improvement in the coefficient of determination (R^2) and reduction in the standard deviation of the regression were also taken to reflect improvements in prediction.

Results

The performance of the regression equations estimated from Houston data as applied to the Pittsburgh population is shown in Table I. The standard deviations of the regressions for Pittsburgh data were calculated from the difference between predicted and actual gestational ages. Interestingly, predicted gestational ages showed less variable divergence from actual values for the Pittsburgh data than for the Houston data from which the prediction equations were obtained. This may be due to a more homogeneous patient population at Magee-Womens Hospital or to consistency in ultrasonographic measurements among a small staff of experienced ultrasonographers.

When the structure of the Houston equations were used to reestimate the regressions with Pittsburgh data, the Houston equations performed quite well (Table II). The coefficients and standard deviation of the regressions can be compared with those of Table I. In general, these comparisons show the figures to be quite similar.

The addition of several fetal measurements generally improves their predictive accuracy. This can be seen

Table II. Reestimation of Houston equations with Pittsburgh data

Equation	Without radius		With radius	
	SD (wk)	R^2	*SD (wk)*	R^2

Four variables				
GA = 10.65 + 0.139(AC) + 0.739(BPD) + 0.63(HC) (FL)	0.85	98.3	0.80	98.5

GA, Gestational age; *BPD,* biparietal diameter; *HC,* head circumference; *AC,* abdominal circumference; *FL,* femur length.

from Table II. For example, the importance of femur length can be inferred by comparing equations 7, 9, and 10 with the corresponding equations 1, 2, and 3. The standard deviation of the regressions with femur length are lower than those without femur length. Of particular note is the fact that the standard deviation of the regressions cannot be improved on by adding variables beyond the two-variable case. That is, the standard deviations for biparietal diameter and femur length, as well as head circumference and femur length, are as low as that obtained when four variables (biparietal diameter, femur length, head circumference, abdominal circumference) are used.

The usefulness of radius length as a predictor of gestational age was assessed by adding radius to each of the regression models shown in Table II. In almost all cases radius provides an independent, statistically significant contribution to the prediction of gestational age beyond that of the variables already in the equation. The standard deviations of the regression are lower and the R^2 values are higher.

To assess how radius compares with other fetal measurements, the best regression equation for each fetal measurement or combination of fetal measurements was estimated, as shown in Table III. The criteria for "best regression" was the same as that used by Hadlock et al.[8]—the lowest standard deviation and highest R^2 associated with the equation in which all variables were significant. Radius did not significantly improve an equation when another long bone, femur length, was included. Radius length, however, improved prediction when fetal measurements other than the femur length (i.e., head circumference, biparietal diameter, abdominal circumference) were used.

Comment

Sabbagha et al.[12] studied the growth rate of the biparietal diameter in 67 pregnant monkeys with known breeding dates. He was able to divide his study group into four percentile divisions: 10th to 24th, 25th to 49th, 50th to 74th, and 75th to 90th. Once a monkey was placed into one of these categories, his subsequent growth would remain within the confines of that percentile range. This was particularly true for the lower (probability 0.92%) and upper (probability 0.93%) end scale. A similar growth pattern exists for the biparietal diameter in the human.[13] Other fetal parameters, however, may not vary in the same direction (e.g., a fetus with a 75th percentile biparietal diameter and 25th percentile abdominal circumference[14]). As a result, the dependence on a single fetal measurement to assess gestational age in the third trimester has a 95% confidence interval of ±3 weeks or more. By combining the gestational age estimates of fetal body parts with varying growth rates (and differential susceptibilities to growth inhibition), Hadlock et al.[7, 8] were able to significantly reduce the confidence interval.

Our data confirm certain aspects of the studies performed by Hadlock et al.[7, 8] while refuting others. Table IV compares the correlation coefficients for the present investigation with Hadlock et al.[8] The femur length was found to be superior to the BPD in both studies as a single measurement of gestational age. Yagel et al.[15] came to a similar conclusion.

Table IV. Correlation coefficients of various fetal measurements versus gestational age

Fetal measurements	*Hadlock et al.*[8]	*Current study*
Biparietal diameter	96.7	96.3
Head circumference	97.3	97.1
Abdominal circumference	96.9	96.5
Femur length	98.0	98.1
Femur length, head circumference	98.0	98.5
Head circumference, abdominal circumference, femur length	98.1	98.3
Biparietal diameter, head circumference, abdominal circumference, femur length	98.1	98.3

The study of Hadlock et al.[8] and the current investigation show a slight increase in R^2 when two, rather than one, fetal parameters are used to evaluate gestational age. The combination of head circumference and femur length resulted in the best coefficient of determination with the least variability. The data in Table III indicate that the addition of other fetal biometric data (biparietal diameter, abdominal circumference, and radius) did not significantly improve the results obtained from the combination of the head circumference and femur length. Although Hadlock et al.[8] state that there is a significant reduction in variability when four parameters rather than one are used to assess gestational age, the data they provide also indicate that the variability and correlation coefficient for head circumference and femur length are comparable to those of the combination of biparietal diameter, head circumference, abdominal circumference, and femur length.

It should be emphasized that neither our data nor the data of Hadlock et al.[8] found a point of diminishing returns by adding up to five fetal parameters in the determination of gestational age, i.e., the error inherent in measuring several distinctly different structures did not significantly affect variability. We therefore concur with Hadlock et al.[8] that a standard ultrasonographic examination should include measurements of the biparietal diameter, head circumference, abdominal circumference, and at least one long bone. By completing a fetal growth profile rather than obtaining one or two selected measurements, the ultrasonographer will be in a better position to detect not only abnormalities of fetal growth but also certain congenital anomalies.

Hadlock et al.[16] have previously shown that regression equations developed from a white population were applicable to fetuses from a population with different socioeconomic and racial characteristics. Our study confirms their findings. Other institutions performing obstetric ultrasonography should not assume that they would obtain comparable results. An institutionally derived regression equation will reduce the variability in the estimation of gestational age while only marginally altering the coefficient of determination. We would, therefore, suggest that each obstetric ultrasonography service evaluate several hundred patients in a manner similar to ours. If the variability in the assessment of gestational age is significantly affected, we would recommend that an institutional, rather than a published, formula be used.

We had hoped that the radius length would further narrow the variability inherent in the ultrasonographic assessment of gestational age for two reasons. First, when the fetal long bones are compared, the growth rates of the femur and radius are the most disparate.[17] Second, with advancing gestation the right femur be-

comes significantly longer than the left, whereas the length of the radius is the same on either side.[17] Thus the varying slopes of the regression equation for femur length and radius length versus gestational age and the increased variability obtained in randomly measuring either the left or the right femur implied to us that radius length would either provide additional information or replace femur length as the long bone measurement of choice. Unfortunately, as outlined on Table III, radius length had the largest variability and poorest correlation coefficient of the five fetal parameters we evaluated. When the radius length was combined with other fetal biometric data it did not significantly improve any of the equations that included femur length. These findings indicate that the theoretic difference between radius length and femur length mentioned previously is not clinically significant.

In conclusion, we have shown that several measurements of fetal size (femur length, head circumference, biparietal diameter, abdominal circumference, and radius length) have a high correlation with gestational age when considered individually. The combination of more than one fetal measurement results in only a slightly higher estimated correlation with gestational age but substantially reduces the error of estimate. For our normal patient population, the combination of head circumference and femur length was the most efficacious. The addition of other fetal parameters did not significantly improve the estimate of gestational age. Finally, we have confirmed the generalizability of carefully obtained fetal biometric data across population groups.

Phase II trial of ifosfamide and mesna in leiomyosarcoma of the uterus: A Gynecologic Oncology Group study

Gregory P. Sutton, MD,[a] John A. Blessing, PhD,[b] Rolland J. Barrett, MD,[c] and Ramon McGehee, MD[d]

Indianapolis, Indiana, Buffalo, New York, Winston-Salem, North Carolina, and Jackson, Mississippi

OBJECTIVE: The purpose of this study was to evaluate the activity of ifosfamide (isophosphamide) in patients with advanced or recurrent leiomyosarcoma not previously exposed to chemotherapy.

STUDY DESIGN: This is a phase II groupwide study of the Gynecologic Oncology Group. Thirty-five patients were treated with ifosfamide 1.5 gm/m^2 daily intravenously for 5 days with mesna (mercaptoethane sodium sulfonate). Fifty-six patients had received prior abdominal hysterectomy and 15 prior radiotherapy. The dose was reduced to 1.2 gm/m^2 daily in patients who had received prior radiotherapy.

RESULTS: Gynecologic Oncology Group grade III or IV granulocytopenia occurred in 4 (11%) patients, and none had grade IV thrombocytopenia. One (2.8%) patient had grade IV neurotoxicity. Partial responses were observed in 6 of 35 (17.2%) patients. The 95% confidence interval for response was 6.6% to 33.7%.

CONCLUSION: These results indicate that ifosfamide has modest activity in patients with advanced or recurrent leiomyosarcomas of the uterus. (Am J Obstet Gynecol 1992;166:556-9.)

Key words: Ifosfamide, mesna, leiomyosarcoma of the uterus

Ifosfamide is an alkylating agent structurally similar to cyclophosphamide, which is highly active in the treatment of a number of nongynecologic and gynecologic neoplasms, including lymphomas[1] and testicular[2] and ovarian carcinomas.[3]

Like doxorubicin, ifosfamide possesses activity in the treatment of soft tissue sarcomas. Bramwell et al.[4] compared cyclophosphamide with ifosfamide in advanced soft tissue sarcomas. The response rate in previously untreated patients was 25% with ifosfamide and 13% with cyclophosphamide. Other authors[5, 6] have confirmed response rates of 23% to 65% in previously treated patients with soft tissue sarcomas.

Because of these promising results, the Gynecologic Oncology Group initiated a phase II trial of ifosfamide and mesna in patients with uterine sarcomas refractory to surgery and radiotherapy but untreated with previous chemotherapeutic agents. In mixed müllerian tumors of the uterus, ifosfamide and mesna produced an overall response rate of 32.2% and a complete response rate of 17.9% in 28 patients evaluable for response.[7] The current report includes patients with leiomyosarcomas of the uterus who have had no prior chemotherapy.

Material and methods

Patients with histologically proved advanced or recurrent leiomyosarcoma of the uterus not amenable to curative therapy but unexposed to prior chemotherapeutic agents were eligible for this study. Additional eligibility criteria included measurable disease that could be defined in at least two dimensions by physical examination or medical imaging techniques. Ascites and pleural effusions were not considered measurable disease. Also required were Gynecologic Oncology Group performance status 2 or better[8]; an interval of ≥3 weeks since any prior tumor-oriented therapy; absence of significant infection; recovery from recent surgery or radiotherapy; and adequate hematologic white blood cell count ≥3000/μl, platelet count ≥100,000/μl), hepatic (serum bilirubin, alanine transferase, and alkaline phosphatase two × normal or less), and renal (serum creatinine ≤2.0 mg/dl or creatinine clearance ≥50 ml/min) function tests. Informed consent was obtained from all subjects, and none was treated until the study was approved by the Human Investigations Committee of the participating institution.

Criteria for exclusion were absence of measurable disease, prior chemotherapy, Gynecologic Oncology Group performance status of ≥3, presence of a second

malignancy excluding squamous or basal skin lesions, or the presence of microhematuria in excess of the institutional lowest normal range.

Ifosfamide was administered intravenously at a dose of 1.5 gm/m² daily for 5 days every 4 weeks. This dose was reduced to 1.2 gm/m² in patients with prior radiotherapy. Mesna was given intravenously, 300 mg/m², every 4 hours for three doses after each dose of ifosfamide. History and physical examination with assessment of evaluable lesions, Gynecologic Oncology Group performance status, serum chemistry results, blood urea nitrogen, creatinine, and microscopic urinalysis were performed before each cycle of therapy, and complete blood cell count and differential and platelet counts were obtained weekly. Chest radiograph was required on entrance to study and every 3 weeks if a marker lesion was present. Abdominal pelvic computed tomographic scans were used unless tumor parameters were assessed by examination or chest radiograph.

Drug administration was delayed after hematologic toxicity until white blood cell count was >3000 μl, platelet count >100,000/μl, and granulocyte count >1500/μl. Patients were considered evaluable for toxicity if just one course of therapy was given and evaluable for response after a single course of therapy if there was clear-cut progression. In other cases patients remained on study until disease progression was noted or adverse effects prevented further therapy. Response duration was calculated from the start of therapy until documentation of disease progression. Patients were considered to have stable disease if there was no progression of disease during therapy for 4 months.

Results

Between May 1986 and June 1989, 36 patients were entered into the study. One patient refused therapy before the first administration, leaving 35 patients evaluable for response and toxicity. The median age of evaluable patients was 53 years (range 32 to 65 years). Twenty-six patients had undergone prior hysterectomy, two had laparotomy only, and seven had had no surgery. Fifteen patients (42.9%) had received prior radiotherapy. Fourteen patients had Gynecologic Oncology Group performance status 0, 13 had Gynecologic Oncology Group performance status 1, and eight had Gynecologic Oncology Group performance status 2.

Response. Table I outlines patient characteristics and the clinical results of therapy with ifosfamide. Six patients (17.2%) had partial responses to therapy, and 10 patients (28.6%) had stable disease. Response duration was 2.9 to 12.4 months, with a median response duration of 3.8 months. Response by Gynecologic Oncology Group performance status is shown in Table I. Median age for responders was 52 years (range 38 to 62 years). Four responses occurred in patients receiving prior radiotherapy; the other two responders had not received radiotherapy. Responders received a median 5.0 courses of chemotherapy (range three to seven courses). Responses by adverse hematologic effects are also detailed in Table I. Median survival is 6.0 months.

Toxicity. Nineteen patients were treated at a dose of 1.5 gm/m²/day for 5 days; the remainder had therapy initiated at the 1.2 gm/m² dose because of prior radiotherapy. Twelve patients (34.4%) experienced Gynecologic Oncology Group grade 3 or 4 leukocytopenia (white blood cell count ≤200/μl), and four (11.4%) had granulocyte counts <1000/μl. The median white blood cell count nadir for all patients with leukocytopenia was 1900/μl (range 600/μl to 3400/μl). Adverse effects are outlined in Table I. No patients developed significant thrombocytopenia. No patient experienced granulocytopenic fever or thrombocytopenic hemorrhage.

Other adverse effects are listed in Table II. Grade 4 neurotoxicity developed in one patient. This patient became lethargic and disoriented but responded to the withdrawal of ifosfamide and mesna. Hematuria was not observed in this patient population in spite of prior

radiotherapy in many subjects. There was no renal toxicity exceeding grade 1 (three patients).

Comment

Uterine sarcomas continue to present a challenge to the gynecologic oncologist. Patients with malignancy confined to the uterus and cervix have a 5-year survival of 50% at best,[9] and those with stage III and IV disease rarely survive for this length of time. Although the use of postoperative pelvic radiotherapy may reduce the risk of pelvic recurrence, this method of treatment has not changed recurrence rates or survival. Furthermore, adjunctive chemotherapy with doxorubicin does not affect survival.[10]

A variety of drugs have been used in the treatment of advanced or metastatic uterine sarcomas. Few early reports separate leiomyosarcomas from other more common types, such as mixed müllerian tumors. Omura et al.[11] compared doxorubicin with or without dacarbazine in 146 evaluable patients with measurable uterine sarcomas. When treated with doxorubicin alone, only four of 41 patients (9.8%) with mixed müllerian tumors responded to therapy. In contrast, seven of 28 patients (25.0%) with leiomyosarcoma responded to doxorubicin. With the addition of dacarbazine, response rates were 22.6% and 30%, respectively. This was the first report suggesting a differential sensitivity among uterine sarcomas to chemotherapy. In a later study, cisplatin produced responses in five of 28 patients (18%) with mixed müllerian tumors refractory to prior doxorubicin.[12] In contrast, only one of 19 patients (5.3%) with refractory leiomyosarcoma responded to cisplatin.[13] Responses to cisplatin in previously untreated patients were also rare. Because of these findings, the Gynecologic Oncology Group has evaluated new agents for the treatment of uterine sarcomas in patients grouped by histologic type.

In a phase II study by the Gynecologic Oncology Group,[7] 32.2% of 28 evaluable patients with mixed müllerian tumors that had not been exposed to chemotherapy responded to ifosfamide therapy. Five patients (17.9%) had complete responses to therapy. These findings suggest that ifosfamide is a drug with single-agent activity in mixed müllerian tumors. Although only 17.2% of leiomyosarcomas were sensitive to ifosfamide in the current report, this degree of activity is comparable to that of doxorubicin as a single agent. These findings suggest that ifosfamide and doxorubicin with or without dacarbazine would be valuable combinations in the treatment of advanced uterine leiomyosarcomas. Furthermore, if response rates >50% or 60% can be attained, such a combination might be considered in the adjuvant therapy of completely resected uterine leiomyosarcomas.

Ifosfamide-based combination regimens are showing promise in the management of soft tissue sarcomas. This drug has been combined effectively with doxorubicin in phase II studies. Schutte et al.[14] reported a 36% response rate, including 6.3% complete responses, in 126 evaluable patients treated with a 1-day regimen of ifosfamide and doxorubicin. Sledge et al.[15] reported 16 of 39 (41%) responders with a similar regimen. Elias et al.[15] added dacarbazine to these two drugs and observed responses in 13 of 29 (45%) patients with three or 10% complete responses. Combinations including ifosfamide in the treatment of uterine leiomyosarcoma will be studied in future Gynecologic Oncology Group trials.

Prenatal diagnosis of autosomal recessive polycystic kidney disease: Variable outcome within one family

Richard A. Barth, MD,[a] Ann P. Guillot, MD,[b] Eleanor L. Capeless, MD,[c] and Jackson J.W. Clemmons, MD[d]

Burlington, Vermont

Autosomal recessive polycystic kidney disease is frequently diagnosed in utero by obstetric ultrasonography. We report a case in which there were varying outcomes of this disorder in three affected fetuses in a family. Recognition of variable expression within one family is important when parents are considering termination of a pregnancy with an affected fetus. (AM J OBSTET GYNECOL 1992;166:560-7.)

Key words: Fetus, abnormalities; fetus, genitourinary tract; fetus, ultrasound studies

Autosomal recessive polycystic kidney disease has an incidence of approximately 1 in 40,000. It is frequently diagnosed in utero by obstetric ultrasonography or can be seen in the newborn with bilateral flank masses, renal failure, or oligohydramnios-related pulmonary hypoplasia. The kidneys are symmetrically enlarged and characterized microscopically by severe cystic dilatation of the renal collecting tubules and ducts. Hepatic fibrosis is always present, and its severity tends to be inversely proportional to the degree of renal involvement. Renal disease dominates the clinical picture in the perinatal period and is often associated with renal failure and early death. Liver disease dominates the presentation in older children, and renal manifestations are frequently mild in this subgroup. We describe a case in which there were varying outcomes in three affected fetuses from one family.

Case report

A 28-year-old woman, gravida 3, para 3, conceived three children affected with the perinatal form of autosomal recessive polycystic kidney disease. Two children died soon after birth, and one is still alive at age 3½ years. Prenatal ultrasonography diagnosed severe disease in two of the siblings, including the one long-term survivor.

This couple's first pregnancy resulted in a female infant at 38 weeks' gestation who died of severe pulmonary hypoplasia at 8 hours. Autopsy results were typical of autosomal recessive polycystic kidney disease. Because of a 25% recurrence risk, the family's second pregnancy was monitored ultrasonographically. Ultrasonography performed at 16.5 and 19.5 weeks' gestation was normal. The family was counseled regarding the variable expression of the disease and the possibility that it could manifest later in pregnancy or childhood.

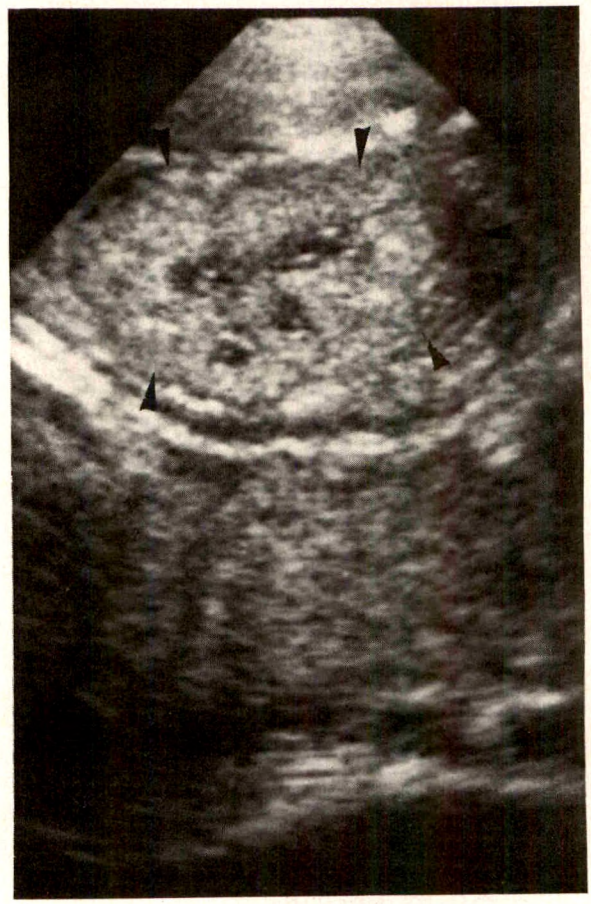

Fig. 1A. Autosomal recessive polycystic kidney disease at 35 weeks' gestation (second affected fetus). Sagittal scan of fetal kidney *(arrowheads)* shows severe enlargement with diffuse increase in echogenicity.

Fig. 1B. Autosomal recessive polycystic kidney disease (second affected fetus). Microscopic section of kidneys shows normal glomeruli with severe cystic dilatation of renal tubules *(arrowheads)*.

The parents elected to carry the pregnancy to completion. Ultrasonography at 35 weeks showed severe oligohydramnios, enlarged fetal kidneys (Fig. 1A), and a small bladder. This pregnancy resulted in spontaneous vaginal delivery at 37 weeks of a male infant who died of severe pulmonary hypoplasia at 28 hours. Autopsy results were diagnostic of autosomal recessive polycystic kidney disease (Fig. 1B). The family conceived a third time and again underwent ultrasonographic monitoring. Ultrasonography at 20.5 weeks showed enlarged and echogenic kidneys diagnostic for this disease. Amniotic fluid was normal and a small fetal bladder was identified. In spite of early fetal diagnosis and the concern for a fatal outcome, the parents elected to continue the pregnancy. A follow-up sonogram at 30 weeks' gestation showed severe oligohydramnios and enlarged echogenic kidneys with a peripheral hypoechoic rim typical of autosomal recessive polycystic kidney disease (Fig. 1C). This pregnancy culminated with a spontaneous vaginal delivery at 37.5 weeks. Postnatal ultrasonography showed enlarged and echogenic kidneys and a normal liver. The child is currently 3½ years old with medically treated hypertension and normal renal function.

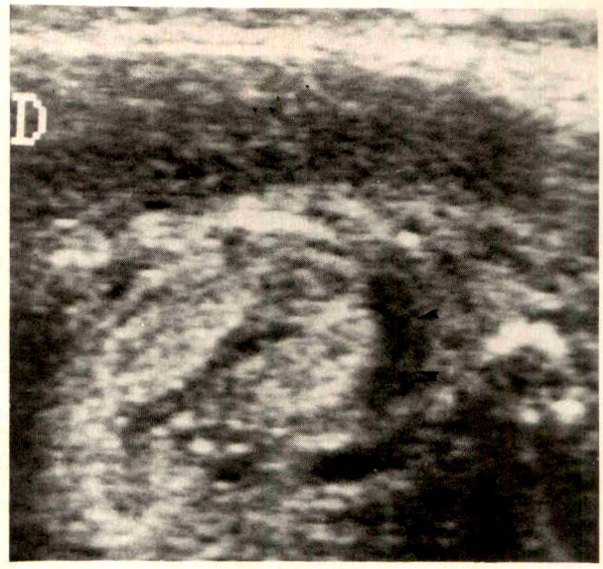

Fig. 1C. Autosomal recessive polycystic kidney disease, 30 weeks' gestation (third affected fetus). Sagittal scan of kidney shows severe enlargement, increased echogenicity, and a peripheral hypoechoic rim *(arrowheads)*.

Comment

Prenatal or neonatal diagnosis of autosomal recessive polycystic kidney disease frequently has a fatal outcome because of renal failure or pulmonary hypoplasia. Previous reports have stated that severity of disease in affected newborns is consistent within a given family.[1] However, this case report supports the potential for prolonged survival, even when previous siblings have died of the severe perinatal form of autosomal recessive polycystic kidney disease. The literature on siblings is limited but supports the concept that variable expression reflects the natural history of the disease rather than the occurrence of separate genetic entities.[2]

When a pregnancy at risk is diagnosed as having a fetus with autosomal recessive polycystic kidney disease, the parents can be counseled with the option of termination; however, it should be noted that the outcome is not invariably fatal. Conversely, the absence of ultrasonographic manifestations on initial fetal evaluation does not exclude the possibility of delayed expression, either in utero or after birth.

Recognition of variable expression within one family is important for genetic counseling or when parents are considering termination of a pregnancy with an affected fetus.

Laboratory and clinical comparison of a rapid versus a classic progesterone radioimmunoassay for use in determining abnormal and ectopic pregnancies

C. Matthew Peterson, MD,[a] Donald Kreger, MD,[a] Pablo Delgado, MD,[b] and Terry T. Hung, MD, PhD[b]

Salt Lake City, Utah, and Miami, Florida

A rapid, solid-phase, nonextraction progesterone kit (n = 36) was compared with an established extraction method, liquid phase tritium radioimmunoassay for progesterone (n = 79). Logistic regression of the rapid method over the extraction method gave a correlation coefficient of r = 0.968. Logistic regression gave a discriminatory zone (abnormal vs normal pregnancy) of 22.58 ng/ml by the rapid method compared with 15 ng/ml for the extraction method (log Y = 0.253 + 0.936 log X). Similar sensitivity (100% and 100%), specificity (63% and 59%), and predictive values of positive and negative tests (positive predictive value = 91% and 75%, negative predictive value = 100% and 100%) were found using a discriminatory level of 15 and 20 ng/ml for the extraction method (n = 79) and rapid method (n = 76), respectively. Clinically, curettage for patients with values less than these discriminatory zones would have given unacceptable rates for termination of a potentially normal pregnancy (38%). Clinical comparison of abnormal (ectopic or abortion) and normal (term pregnancy) outcomes in two populations of women presenting with first-trimester bleeding revealed that progesterone levels would accelerate the workup in only a small percentage (27%, 15 of 56) of patients with ectopic pregnancies. The rate of ruptured ectopic pregnancies in the observed patients was similar (20%, 3 of 15) to studies using progesterone levels prospectively. Therefore in this retrospective analysis progesterone levels would have given no greater benefit than conventional management. (Am J Obstet Gynecol 1992;166:562-6.)

Key words: Progesterone levels in abnormal pregnancies

Ectopic pregnancies have abnormal corpus luteal function not attributable to a decrease in bioactive human chorionic gonadotropin (hCG).[1, 2] Keko and others[3-5] have suggested that serum progesterone levels provide rapid differentiation between normal and abnormal pregnancies (ectopic, inevitable abortion). In those studies a rapid, nonextraction assay kit was used, and each laboratory established its own discriminatory zone. Normal pregnancies[1, 3, 4, 6-8] or "patients presenting to the emergency room identified by housestaff as being at risk for ectopic pregnancy,"[5, 9] were used as controls.

The purpose of our study was (1) to compare the precision of a nonextraction, solid-phase, iodine 125 radioimmunoassay (RIA) procedure to an extraction, liquid-phase, tritium RIA procedure, (2) to determine the discriminatory value of each assay necessary to differentiate a bleeding intrauterine pregnancy that progresses normally to a live birth from an abnormal pregnancy (ectopic or inevitable abortion), and (3) to retrospectively evaluate the clinical usefulness of serum progesterone measurement compared with routine management.

Material and methods

Patients. From October 1988 to February 1989 all patients seen in the emergency room at the University of Miami who were at >4 weeks and <12 weeks' gestation (from last menstrual period) with abdominal pain and abnormal uterine bleeding had a serum sample frozen at −20° C for later evaluation. Documentation of pregnancy by positive β-hCG, absence of ovulation-inducing drugs, serial β-hCG levels, ultrasonography, serial examinations, and a final diagnosis by pathology specimen was available for 79 patients. Patients not taken immediately for laparoscopy or laparotomy (positive culdocentesis) were followed with β-hCG titers every 48 hours. Transvaginal ultrasonography was obtained when titers failed to rise ≥66%, a mass was palpated, or marked abdominal tenderness was noted. If all pregnant patients seen with abnormal vaginal bleeding and abdominal tenderness in the emergency room at Jackson Memorial Hospital required ultrasonography, the demand potentially could exceed the supply level of that hospital. Thus the senior residents triaged

patients according to signs and symptoms and requested a priority ultrasonography for "high-risk" patients.

In the study sample from the University of Miami, 42 ectopic pregnancies, 21 inevitable or spontaneous abortions, and 16 pregnancies with first trimester uterine bleeding subsequently carried to term with delivery of a normal infant were investigated. Serum progesterone levels were performed in these samples by ether extraction with a recovery >90% and liquid-phase, ^{3}H RIAs.[10] Sensitivity, specificity, and predictive indices were determined.

In 36 cases (10 randomly selected ectopic pregnancies, 10 randomly selected inevitable or spontaneous abortions, and 16 intrauterine pregnancies carried to term), adequate serum was available in the samples to perform duplicate, nonextraction, solid-phase, ^{125}I RIAs (Coat-A-Count, Diagnostic Products Corporation, Los Angeles, Calif.). The manufacturer's methodology with a 3-hour incubation was used. The extraction method and rapid method were compared by methods described by Rodbard.[11] Cross-reactivity with 17-hydroxyprogesterone in the classic extraction method ^{3}H progesterone RIA was 6.7% and 0.3% in the nonextraction rapid progesterone kit.

Additionally, from January 1990 to November 1991, 40 patients were studied with the same criteria at the University of Utah Hospital. In this study 14 ectopic pregnancies, 8 inevitable or spontaneous abortions, and 18 pregnancies with first trimester uterine bleeding, which subsequently carried to term delivery, were evaluated by the rapid method. Duplicate, nonextraction, solid-phase, ^{125}I RIAs (Coat-A Count, Diagnostic Products Corporation, Los Angeles, Calif.) were performed on these patients. The sensitivity, specificity, and predictive values were determined on the combined group (n = 76) from both institutions and compared with the patients evaluated by the extraction method (n = 79).

Results

Fig. 1 shows the serum progesterone levels for patients with ectopic pregnancies (n = 42), inevitable abortions (n = 21), and normal intrauterine pregnancies carried to term (n = 16), with the extraction, liquid-phase, tritium RIA method (extraction method). The intraassay and interassay coefficients of variation were 7.5% and 9.5%, respectively. The sensitivity and specificity of a level <15 ng/ml in detecting an abnormal pregnancy was 100% (63/63) and 63% (10/16), respectively; hence, the predictive value of a positive test (<15 ng/ml = abnormal pregnancy) was 91.3% (63/69) and of a negative test (>15 ng/ml – normal pregnancy), 100% (10/10).

Fig. 1 also shows the serum progesterone in 76 patients evaluated by the rapid, nonextraction, solid-phase, ^{125}I RIA method (rapid method). The intraassay and interassay coefficients of variation were 11% and 12%, respectively. The rapid kit using a discriminatory zone of <20 ng/ml to detect an abnormal pregnancy (n = 76; University of Miami, n = 36; University of Utah, n = 40) had a sensitivity of 100% (45/45), a specificity of 59% (20/34), and positive and negative predictive indices of 75% (42/56) and 100% (20/20), respectively.

The coefficient of variation between the rapid method and the extraction method at levels >20 ng/ml (by rapid method) was 13.8% and at levels <20 ng/ml, 20.2%. Logistic regression of the rapid method over the extraction method gave a correlation coefficient of r = 0.968 (n = 36). With Rodbard's methodology, the equation $\log Y = 2.53 + 0.936 \log X$ or $Y = 1.79X^{0.936}$ was derived.[11] This gave a discriminatory zone (abnormal vs normal pregnancy) of 22.58 ng/ml by the rapid method compared with 15 ng/ml for the extraction method. Using 22.58 ng/ml as the discriminatory zone gave the same sensitivity, specificity, and predictive values as 20 ng/ml in the rapid assay.

The clinical presentation of the patients studied from the University of Miami and the University of Utah prompted an immediate laparoscopic evaluation in 73% (41/56) of the ectopic pregnancies. In 27% (15/56) a rapid serum progesterone within 3 hours would have prompted an ultrasonographic evaluation before 48 hours when the second quantitative β-hCG was obtained. In 80% (12/15), observation was continued after the 48-hour β-hCG titer result because of equivocal findings noted by ultrasonography. In 20% (3/15) actual ultrasonography findings prompted laparoscopy. If low progesterone levels in association with no intrauterine pregnancy by transvaginal ultrasonography with a β-hCG ≥2500 mIU/ml were used to decide on immediate intervention by laparoscopy, 27% (4/15) of patients observed might have proceeded to earlier laparoscopy.

If extraction method progesterone levels (≤15 ng/ml) were used to indicate immediate intervention, including curettage, 38% (6/16) of intrauterine pregnancies would have been terminated. If the rapid progesterone level (<20 ng/ml) were used to prompt curettage, 38% (7/18) of intrauterine pregnancies would have been terminated. All intrauterine pregnancies had progesterone levels >9.8 ng/ml by the extraction method and 11.5 ng/ml by the rapid method.

In patients who underwent laparoscopy or laparotomy on presentation, 61% (25/41) had ruptured ectopic pregnancies and 39% (16/41) had unruptured ectopic pregnancies. In the group observed >72 hours before operative intervention, 20% (3/15) were ruptured and 80% (12/15) were unruptured.

A total of 48% of the abortions (14/29) were diagnosed within 48 hours by clinical features and ultra-

sonography. The remaining 52% (15/29) were observed. Of these, 33% (5/15) underwent laparoscopy and curettage.

Comment

This study demonstrates the need to evaluate available rapid progesterone kits compared with a published methodology to define appropriate discriminatory levels in each clinical setting before use. The variation rates in the two methods noted by clinical outcome (predictive values of positive and negative tests) prompted an elevation of the discriminatory value from 15 ng/ml to 20 ng/ml using the rapid progesterone kit. With this elevation in the discriminatory zone, a similar

predictive value of a positive test (<20 ng/ml) of 75% (vs 91% for extraction) and of a negative test (>20 ng/ml) of 100% (vs 100% for extraction) was obtained for the rapid progesterone kit. Logistic regression indicated the discriminatory zone should be 22.58 ng/ml for the rapid progesterone kit. Thus clinicians deciding to use progesterone levels must define in their laboratories appropriate discriminatory zones on the basis of the methodology used. No intrauterine pregnancy had a progesterone level <9.8 ng/ml by either method. While this study gave an acceptable predictive index of a negative test using a value >20 ng/ml as the discriminatory zone, we can envision that higher levels of progesterone may be found in such conditions as cornual ectopics.

It has been suggested that the incidence of rupture of ectopic pregnancies may be reduced with the use of a rapid progesterone and a transvaginal ultrasonography. In our experience, which did not use the serum progesterone prospectively, the incidence of ruptured ectopic pregnancy in the group observed longer than 72 hours (20%, 3/15) was similar to other reports using a serum progesterone in the work-up.[7] Additionally, in a majority of cases (80%, 12/15) ultrasonography was not diagnostic for an ectopic, and observation was continued. However, in 20% (3/15), ultrasonography prompted immediate laparoscopy. If a low progesterone level combined with an hCG level ≥2500 without an intrauterine pregnancy by ultrasonography was used to prompt laparoscopy, 27% (4/15) would have been evaluated sooner. The fact that rupture of ectopic pregnancies occurred during the work-up emphasizes the need for a high degree of suspicion throughout the evaluation. Progesterone levels have been thought to expedite the diagnosis through further studies (i.e., ultrasonography or laparoscopy); however, in this study ultrasonography was nondiagnostic in 80% and the decision to evaluate by laparoscopy again fell to the practitioner. In this series, it is not clear that a benefit greater than our routine evaluation would result from the use of a progesterone level as part of the work-up.[7] The discriminatory values chosen also gave unacceptable rates for termination of pregnancies by curettage with low progesterone values with a significant percentage subsequently carried to term (38%).

This study is the first to use a nonextraction rapid progesterone kit to associate low progesterone values in abnormal pregnancies (ectopic or inevitable abortion) with a control group of similarly presenting pregnancies with abnormal uterine bleeding and abdominal pain who subsequently carried to term. Former studies have used normal pregnancies[1, 3, 4, 6-8] or "patients presenting to the emergency room identified by housestaff as being at risk for ectopic pregnancy."[5, 9] Although this may seem a technicality when determining the usefulness of a testing procedure, the control group must adequately represent the groups requiring differentiation. Radwanska et al.[12] previously documented this finding with an extraction-based, rapid, competitive, protein-binding technique.[13]

In reality, the use of serum progesterone in an attempt to reduce the incidence of ruptured ectopic pregnancies prompts an expedited, complete evaluation in a small proportion of the patients presenting with symptoms that may indicate an ectopic pregnancy. In many cases, as demonstrated in this study, this could be initiated by a high degree of suspicion on the part of the practitioner. In clinical settings where the demand for ultrasonography/laparoscopy may exceed the supply, serum progesterone levels may help determine those most likely to benefit from earlier screening; however, this has not been documented to date. Whether the combination of hCG and progesterone values can prospectively predict an asymptomatic abnormal pregnancy has not yet been adequately addressed. If progesterone levels are obtained in the evaluation of potential ectopic pregnancies, the discriminatory value chosen should be set to detect the majority of ectopic pregnancies (maximal sensitivity, maximal predictive value of a negative test).

Progesterone levels alone in the symptomatic patient should not prompt curettage and add only supportive evidence of an abnormal pregnancy, which prompts further diagnostic procedures (transvaginal ultrasonography or laparoscopy). This retrospective study demonstrates that in two institutions the rate of ruptured ectopic pregnancies as an endpoint would not have been reduced further by the use of progesterone levels than studies using it prospectively; therefore, its utility is questionable.

The accuracy of auscultatory detection of fetal cardiac decelerations: A computer simulation

Barry S. Schifrin, MD, Jaim Amsel, MA, and Gary Burdorf, PhD
Tarzana, California

To evaluate current practices of auscultation for the detection of decelerations, we used a computer to generate contractions and late decelerations and perform the counting. The baseline rate ranged from 110 to 180 beats/min. The duration of the deceleration ranged from 1 to 2 minutes, and the amplitude of the deceleration ranged from 10 to 90 beats/min. The onset of the decelerations ranged from 0.4 to 0.7 of the length of the contraction. Counting was begun at 80%, 100%, and 120% of the contraction length. The duration of counting varied between 15 and 60 seconds. A multicount algorithm obtained three 10-second counts separated by 5 seconds. Results were classified by the ability to detect rates below 120, 100, or 80 beats/min (threshold determination) or 20 and 25 beats/min below the baseline rate (subtraction determination). The baseline rate and deceleration amplitude had the greatest effect on accuracy. The higher the baseline rate and the smaller the deceleration amplitude, the less accurate was detection. Multiple counts were more accurate than the single-count strategy, and subtraction detection was more accurate than threshold detection. The effects of counting error are briefly described. This model, which requires clinical confirmation, nevertheless emphasizes the potential inaccuracies of many popular schemes of auscultatory surveillance, even for the detection of prolonged or sustained decelerations. Certain modifications of auscultatory practice may improve the accuracy of this technique. (Am J Obstet Gynecol 1992;166:566-76.)

Key words: Auscultation, decelerations, computer

Auscultation of the fetal heart rate (FHR) as a measure of fetal welfare was introduced into clinical medicine in the second decade of the nineteenth century. The first scientific treatment appeared as an appendix to the second edition of Laennec's treatise on the stethoscope—the "happy idea" of his friend Kergaradec.[1] The first detailed monograph devoted exclusively to fetal auscultation was written by Kennedy in 1845.[2] Although modest, additional enhancements were made over the next century; little research was devoted to the validation of this universally applied but often contradictory technique. Indeed, to this day there has been no systematic study of the impact of auscultation on fetal outcome.

Several reports of the accuracy of clinical auscultation have concluded that obstetric personnel cannot count the FHR accurately or meaningfully, although they

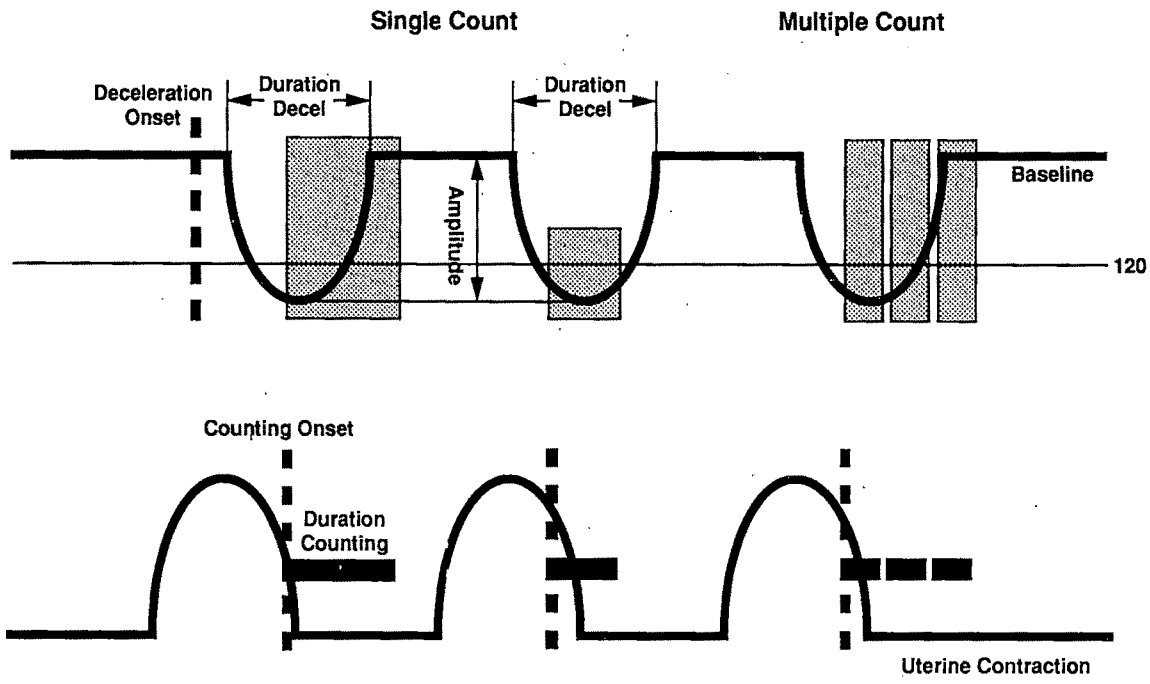

Fig. 1. Components of fetal auscultation. Schematic representation of factors evaluated in this study.

seem to count most accurately when the heart rate is within the normal range.[3-5] The greater the deviation from the average rate, the greater the range of error and the greater the tendency to correct toward the mean. Miller et al.[6] asked experienced labor and delivery physicians and nurses to ascertain the presence of decelerations and other features of the heart rate pattern from fetal heartbeats recorded on tape. Not only were these clinicians unable to reliably identify certain obvious decelerations or features of baseline rate of variability, they could not match auscultatory findings with simultaneous electronic fetal monitor tracings.

In spite of the limitations of auscultation, the results of several recent clinical trials of electronic fetal monitoring purportedly support the notion that auscultation is comparable to electronic monitoring of the FHR.[7, 8] On the basis of these and other studies, the *Guidelines for Perinatal Care* published by the American College of Obstetricians and Gynecologists and the American Academy of Pediatrics[9] seemingly permit auscultation, without electronic fetal monitoring backup, for the evaluation of fetal well-being during labor, irrespective of the risk status of the mother or fetus.

Stimulated by these considerations, we undertook a systematic analysis of clinical auscultation. Rather than compare, as others have, the practical accuracy of counting or the ability to detect decelerations under test or clinical conditions, we chose a different model with which to begin to examine the problem. Using computer simulation, we evaluated the impact of current clinical practices of auscultation on the detection of decelerations. We systematically explored the effect of varying the baseline rate, along with the amplitude, onset, and duration of decelerations on the detection of decelerations. We also explored the impact of varying the onset and duration of counting, and we briefly illustrate the impact of counting error. Analysis of this model suggests that features of the deceleration and, to some extent, the duration of auscultation may profoundly influence the detection of decelerations. Certain modifications of auscultatory practice, however, may improve its accuracy.

Material and methods

For this evaluation all simulations and counting were done by desktop computer (IBM-PC Model AT). The parameters were established by the investigators to encompass the range of heart rate features customarily encountered in clinical practice and to attempt to duplicate popular schemes of clinical surveillance. Fig. 1 provides a schematic illustration of the test protocol. Table I enumerates the values used for the independent variables. The computer generated both contractions and decelerations according to the following scheme: The length of the uterine contraction was normalized to a duration of one minute. The contraction amplitude was not varied. The baseline rate ranged from 110 to 180 beats/min. The onset and return to baseline of all decelerations were symmetric and plotted

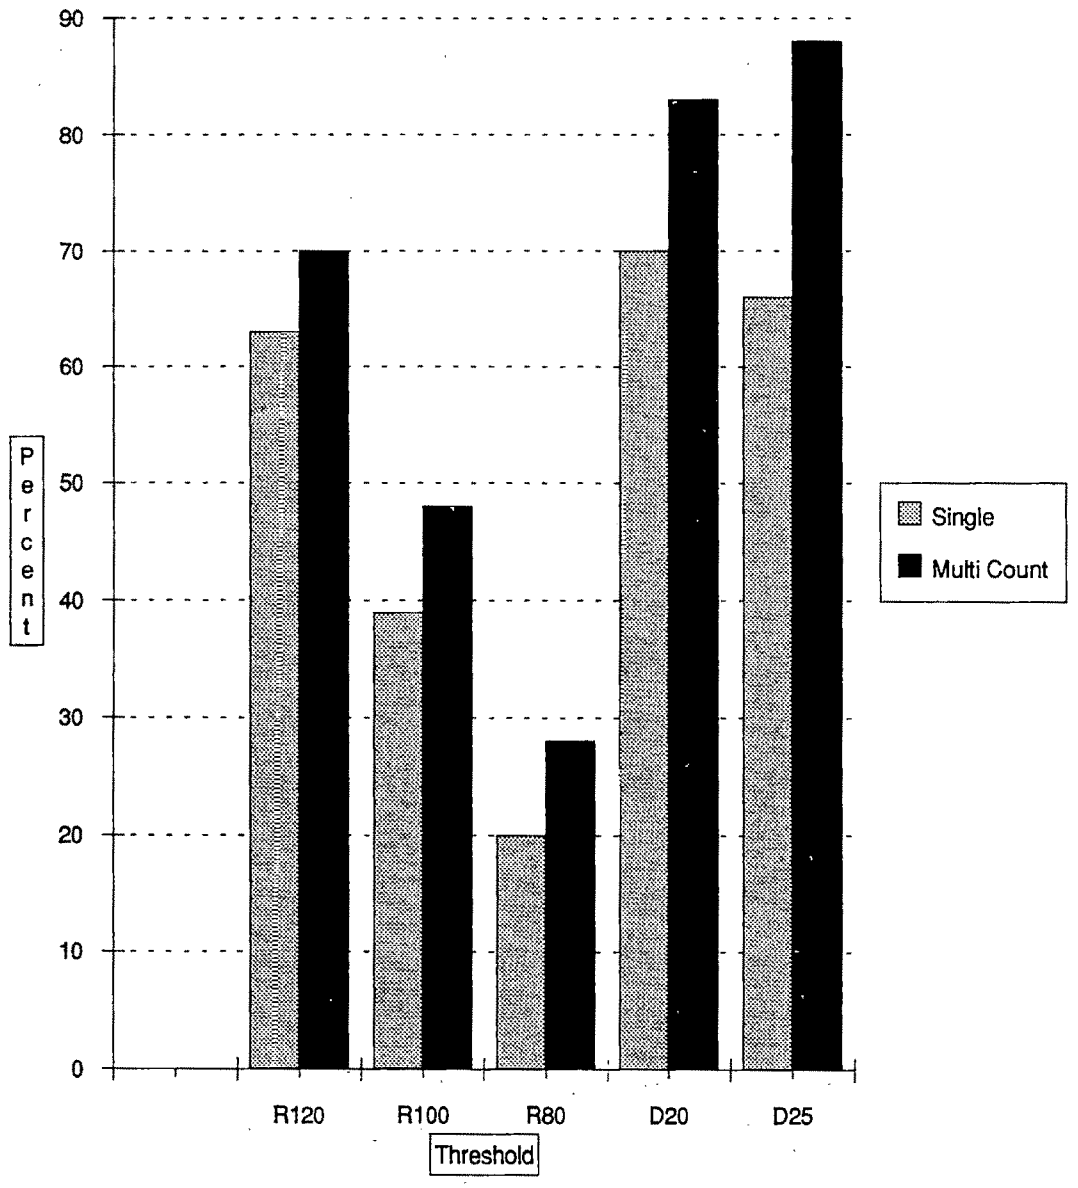

Fig. 2. Detection of decelerations according to threshold for single and multicount cases. In each instance multicount technique detects a greater proportion of decelerations than does single-count technique. *R120,* Threshold 120 beats/min; *R100,* threshold 100 beats/min; *R80,* threshold 80 beats/min; *D20,* threshold 20 beats/min below baseline; *D25,* threshold 25 beats/min below baseline.

as a sine function of the heart rate. The duration of the deceleration ranged from 1 to 2 minutes, and the amplitude of the deceleration ranged from 10 to 90 beats/min. The onset of the decelerations ranged from 32 to 42 seconds into the uterine contraction (0.4 to 0.7 of the length of the contraction). Depending on their duration and amplitude, the decelerations would be classified as either late decelerations, variable decelerations with slow return, or prolonged decelerations.

Because the end of the uterine contraction will vary depending on whether contractions are determined by patient perception, palpation of the abdomen, or electronic tocodynamometry, we initiated counting at 80%, 100%, 120%, and 150% of the contraction, corresponding to 48, 60, 72, and 90 seconds after the onset of the prototypic (1-minute) contraction. The duration of counting varied between 15 and 60 seconds; the computer made the appropriate multiplication to obtain the rate in beats per minute. We also implemented a multicount algorithm as follows: Instead of a single count as described, we obtained three 10-second counts separated by 5 seconds between counts. The lowest of the three counts was considered the detected rate.

Table I. Values of independent variables used in study

Baseline rate (beats/min)	110, 120, 130, 140, 150, 160, 170, 180
Decelerations	
Duration (min)	1.0, 1.5, 2.0
Amplitude (beats)	10, 20, 30, 40, 50, 60, 70, 80, 90
Onset (min after onset of uterine contraction)	0.40, 0.55, 0.70
Counting	
Onset (min after onset of uterine contraction)	0.8, 1.0, 1.2, 1.5
Duration	
Single count (sec)	15, 30, 60
Multicount (No. of 10 sec counts)	3
Contraction	
Duration (min)	1

Table II. Detection of amplitude of decelerations according to parameter

Parameter	*Single count*	*Multicount*	*Parameter*	
			High	*Low*
Baseline	74	93	110	180
Deceleration	74	93	90	10
Duration of deceleration*	83, 59	97, 90	2.0	1.0

Duration of count*	85, 59	—	15	60
Start of count	74	93	0.8	1.5
Average	74	93	–	—

*High and low

There is no uniform agreement as to which heart rate shall be accepted as indicative of a fetal deceleration. Although 120 beats/min is generally accepted as the lower limit of normal, some recommend using 100 or 110 beats/min, others 80 beats/min. Accordingly, we have classified the results according to the ability to detect rates below 120, 100, or 80 beats/min (threshold determination). In addition, we also explored the impact of making the critical level of detection 20 and 25 beats/min below the baseline rate. This involved subtracting the detected rate from the baseline rate (subtraction determination).

Because this model is based exclusively on parameters established by the investigator (a deterministic model), the results are presented simply according to the amount of the deceleration detected and, more importantly, the frequency of detection of decelerations for each parameter studied. The dependent variable, deceleration detected, was defined as 1 for those cases in which the calculated rate during the period of counting satisfied the selection criteria and 0 otherwise. The duration of counting was excluded in the multicount examples. We emphasize that the program distributed all the independent variables evenly across the chosen range; that is, there were equal numbers of decelerations at 10, 30, 50, and 70 beats/min and equal numbers lasting 1, 1.5, and 2 minutes. This does not reflect the distribution of decelerations in clinical practice (see subsequent text).

We briefly explored the impact of erroneous counting on the detection of decelerations. We limited the potential error to the addition and/or subtraction of one or two beats to the count, corresponding to an error of one beat at the beginning and/or end of the count. The potential errors of counting may be represented as follows:

$$\text{Calculated rate} = \frac{\text{True count } (\pm 2 \text{ beats}) \cdot 60}{\text{Duration of counting (seconds)}}$$

Results

For the evaluation of this model, we generated 10,368 records, including 7776 single-count and 2592 multiple-count records. For the single-count strategy, counting detected, on average, about 74% of the amplitude of the deceleration with a range of 59% to 85% according to the independent variable. For the multicount strategy, counting detected on average 93% of the amplitude to deceleration, with a range of 91% to 97% (Table II). Identifying a drop in heart rate as a deceleration, however, was influenced dramatically by the threshold criteria (120, 100, or 80 beats/min or a drop of 20 or 25 beats/min), the technique of counting (single count or multicount), the features of the deceleration, and the features under the control of the listener (Table

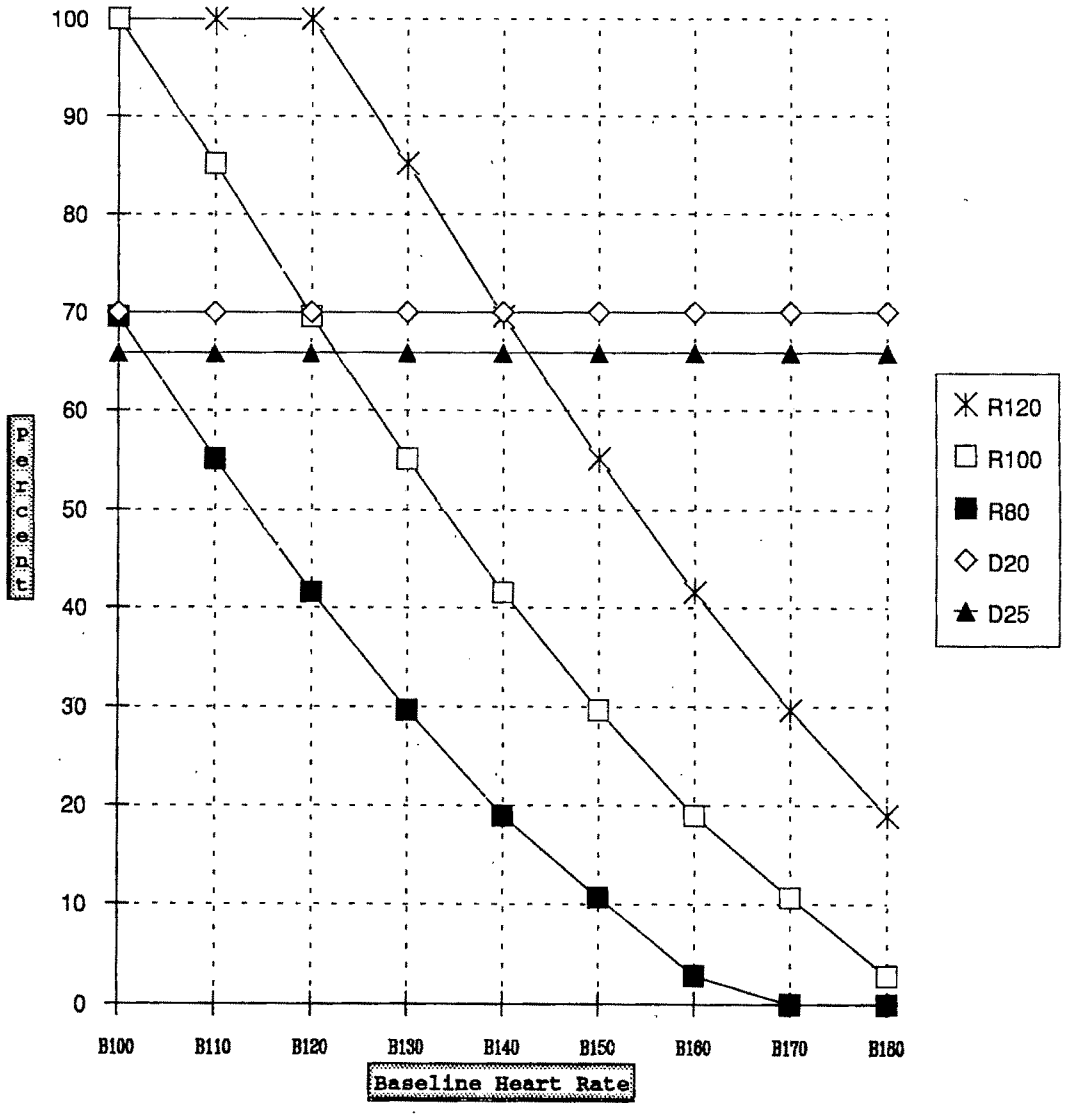

Fig. 3. Detection of decelerations according to baseline heart rate and counting threshold. When threshold involved fixed heart rate (i.e., 100 beats/min), then the higher the baseline rate, the lesser was the accuracy of detection. For subtraction techniques *(D20, D25)*, accuracy was not affected by baseline rate.

Table III. Detection of decelerations according to parameter

Parameter	*Single count*	*Multicount*	*Parameter*

*High and low.

III, Fig. 2). The baseline heart rate and the amplitude of the deceleration had the greatest effect (Figs. 3 and 4). The higher the baseline rate and the smaller the amplitude of the deceleration, the fewer decelerations were detected (Table IV). The longer the duration of the deceleration and the later its onset in the contraction cycle, the more readily was the deceleration detected (Fig. 5). The start of the deceleration played only a small

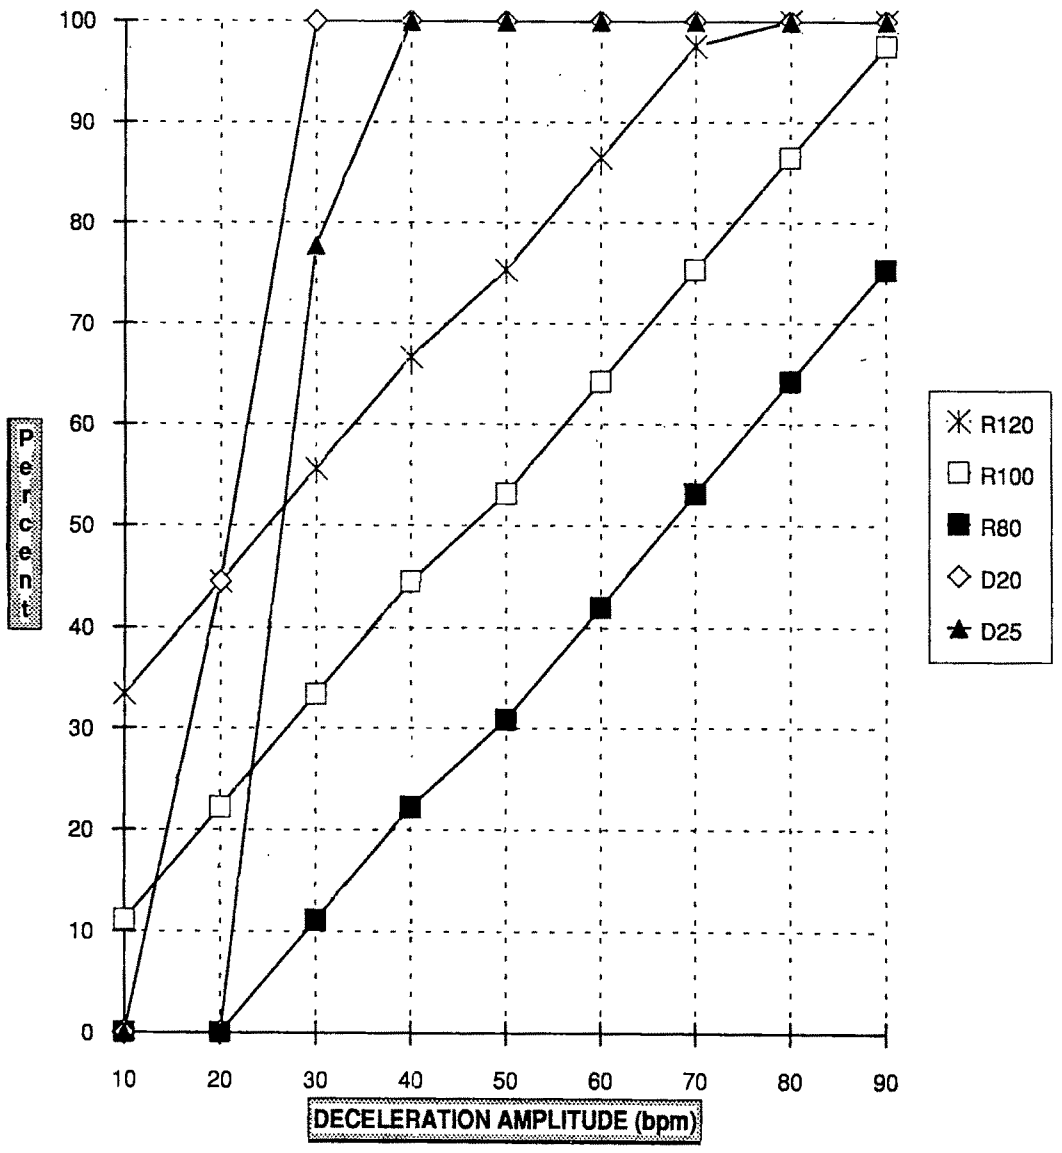

Fig. 4. Detection of decelerations according to deceleration amplitude and counting threshold. Irrespective of counting threshold, the greater the deceleration amplitude, the greater was the accuracy of detection.

role in the detection of decelerations and the determination of their amplitude. The onset of deceleration played no role in the detection of decelerations.

Factors under control of the examiner had limited impact on the detection of decelerations. Early onset of counting was somewhat more accurate than later onset, but this depended on features of the deceleration. Beginning to count after the end of the contraction (1.5 minutes) was only effective when decelerations were prolonged. Shorter counts were more accurate than longer ones (Fig. 6), but this depended on the duration of the deceleration. If the deceleration were relatively short and the duration of counting long, a considerable amount of baseline period would be counted and most decelerations would be missed. On the other hand, with prolonged decelerations the duration of counting did not have an impact on the frequency of detection.

As expected, for every parameter, the higher the threshold, the more decelerations were detected. Fig. 2 compares the detection rate for each threshold level. There is about a 20% reduction in detection as the threshold is lowered by 20 beats/min. Similarly, for every parameter multicount was better than single count. It provided only marginal improvement, however, over the early (0.8 or 1.0 minute), 15-second count. Because 92% of the minimal counts were obtained in either the first or the third epoch of counting, dropping the second 10-second counting period made little practical difference in the detection frequency.

When the basis for the detection of a deceleration involved a drop of 20 or 25 beats/min from the base-

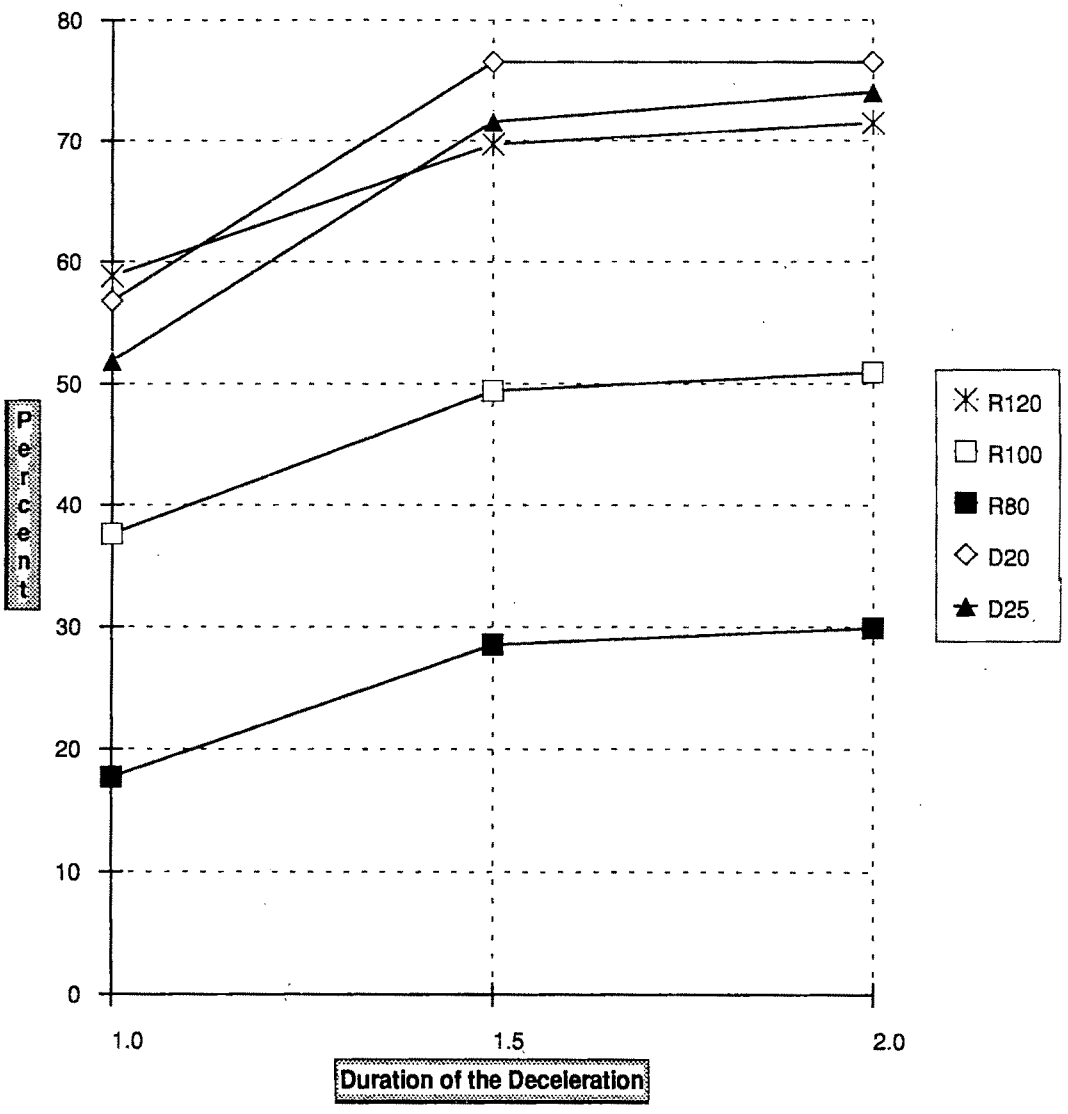

Fig. 5. Detection of decelerations according to duration of decelerations and counting threshold. The longer the duration of the deceleration, the greater the accuracy of detection.

Table IV. Detection of decelerations: Influence of baseline rate and deceleration amplitude

Baseline (beats/min)	*Threshold of 100 beats/min (%)*								
	10	*20*	*30*	*40*	*50*	*60*	*70*	*80*	*90*
110	0	82	93	96	96	100	100	100	100

line, detection accuracy improved considerably but only at higher baseline rates (Figs. 2 and 3). Although this strategy, however, can detect >75% of decelerations of 30 beats/min in amplitude, it detects none of lesser amplitude. Ultimately, in this model the most accurate technique combined the multicount strategy with the 20 to 25 beats/min drop in heart rate from the baseline.

Table V lists the potential deviation for one or two

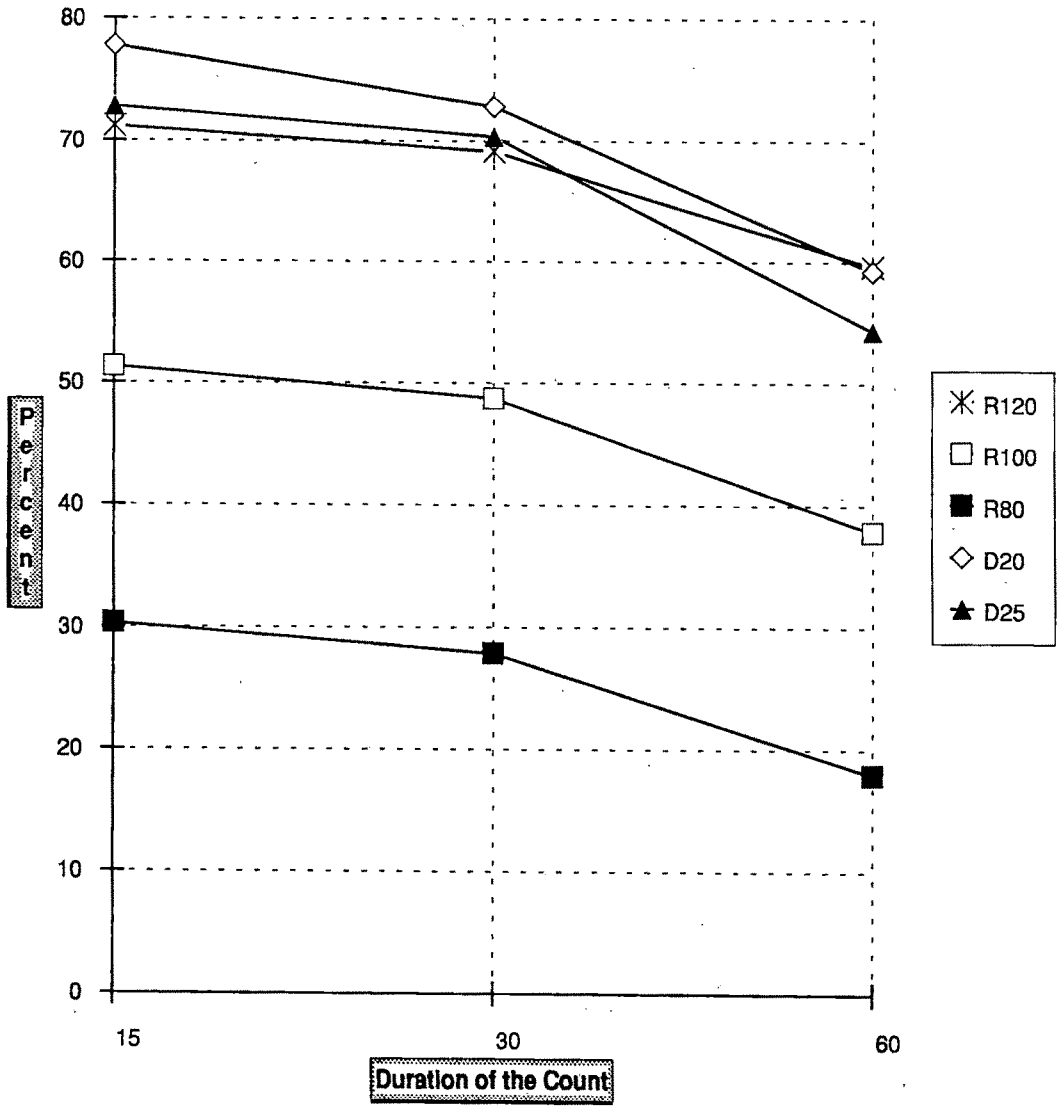

Fig. 6. Detection of decelerations according to counting duration. The longer the count, the lesser the accuracy.

beats of error per counting period. The shorter the count, the larger the multiplier and the greater the potential error. The error, however, is unrelated to the actual FHR. The impact on detection of decelerations according to the duration of counting is illustrated in Fig. 7.

Comment

We again emphasize that the model presented here is based on simulated and not clinical data. It is a limitation of this study that we have not attempted to match the distribution of baseline rates and the features of these decelerations to a clinically determined distribution. We are unaware of such an analysis, nor are we aware of any attempt to determine the consistency and reliability of the clinical detection of the end of the contraction. Those articles dealing with the accuracy of auscultation show a considerable bias in the way the heart beats are counted, especially at high and low rates.[3-6] We have not dealt here with sinusoidal patterns, decreased variability, accelerations, other types of decelerations, or those patterns associated with neurologic handicap. These electronic fetal monitoring patterns rarely involve severe decelerations and seemingly cannot reliably be detected by auscultation.[6, 10-13] These considerations underscore our belief that the data presented here are important for their trends, not for the actual percentages.

Nevertheless, these results bring into focus the potential problems of many popular schemes of auscultatory surveillance, even for the detection of deep or sustained decelerations. The detection of decelerations

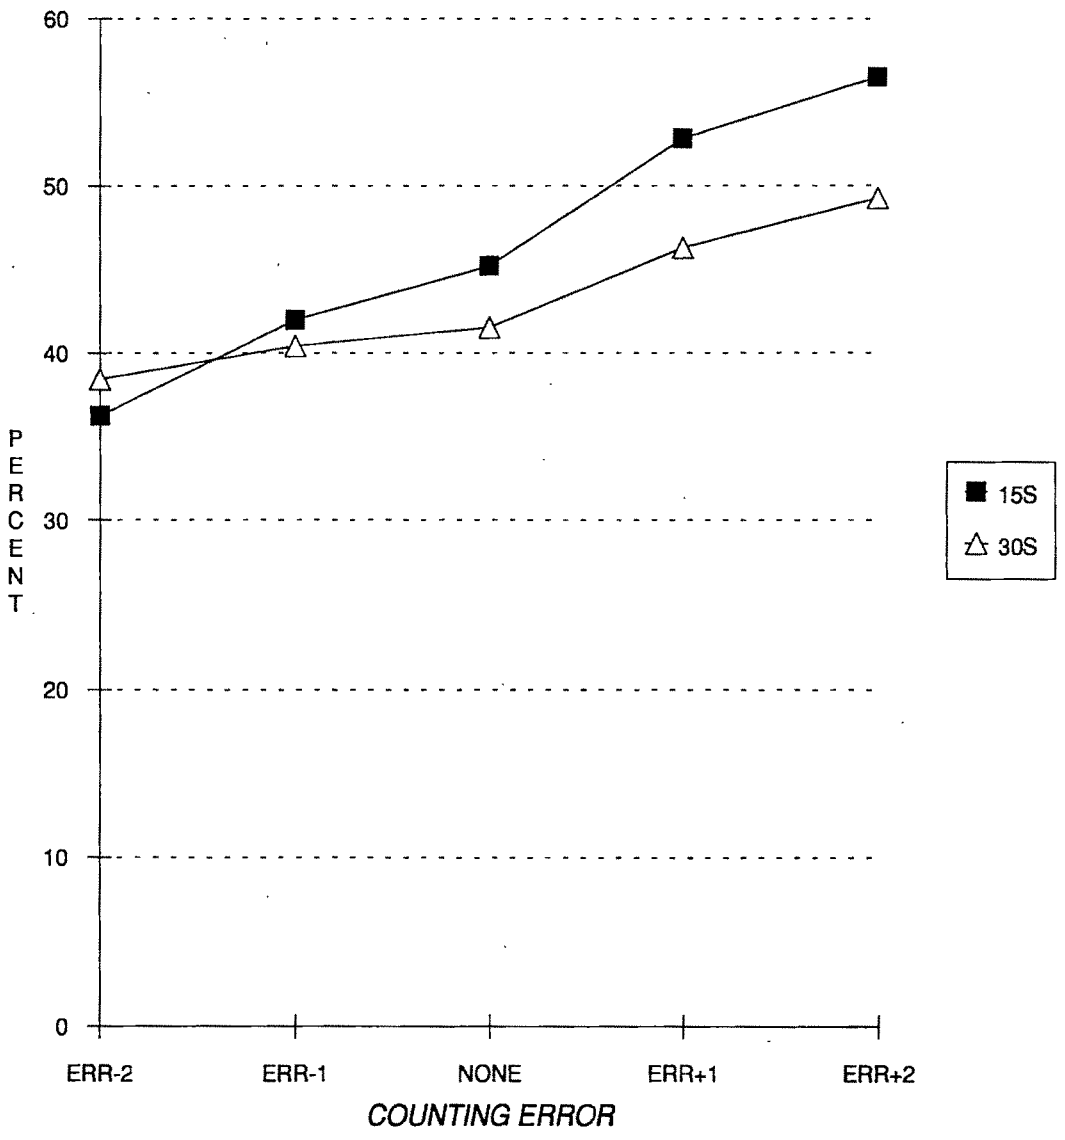

Fig. 7. Effect of counting error on accuracy of detection of decelerations. The shorter the count, the greater was the potential error (see text).

varies considerably, depending on the technique of counting (single count, multicount), the threshold criteria (120, 100, or 80 beats/min or a drop of 20 or 25 beats/min), along with the baseline rate and amplitude of decelerations, and, to a lesser extent, the onset and duration of the deceleration. While factors under the control of the health care provider had only a small effect on accuracy, nevertheless, detection accuracy deteriorates with increasing delay in the onset of counting and with increasing duration of counting.

The results of this model provide no support for counting fetal heartbeats during 1 minute. Unless decelerations are prolonged, this duration of counting diminishes the yield. While multiple, short-lived counts were most accurate, single, short counts (e.g., 15 seconds) were only minimally less accurate. In this respect we have briefly considered the potential impact of counting error on this simulation. Although the shorter counting periods were most accurate in this simulation, this advantage is potentially offset by the greater potential error in counts of short duration. The 10-second count used for the multiple count would be expected to carry the greatest potential error, but this may be offset by the repetitive counts.

Compared with the use of a threshold level of heart rate (e.g., 120 beats/min) to determine fetal decelerations, a critical drop in rate from the baseline seems to provide a more reliable detection scheme, especially if

the baseline rate exceeds 140 beats/min. While the accuracy of detection is improved by this strategy, even this approach will miss about 25% of the decelerations of 30 beats/min amplitude. It may not be possible to optimize auscultation for the detection of smaller decelerations, because the likelihood of error or normal variation will doubtless exceed by manyfold the detection of fetal decelerations. This is not to say that small decelerations are insignificant, only that their reliable detection, in this model at least, seems insurmountable. Whether the critical level should be established at 20 or 25 beats/min or some other value below the established baseline must be determined clinically.

Both these data and the potential errors of counting need to be confirmed in clinical studies. If the model proves accurate, it suggests the need for a fundamental shift in the acquisition and approach to auscultation data. The importance of the baseline rate in assessing decelerations cannot be overemphasized. If the baseline rate is <120 beats/min, as prevails in a number of postdate pregnancies, the normal variation in counting will needlessly alarm the physician or nurse every time the heart rate is counted, irrespective of the presence of decelerations. With high baseline heart rates, the determination of decelerations with the threshold technique becomes insurmountable. At a baseline rate of 160 beats/min, considered the upper range of normal, only half of the decelerations of 50 beats/min were detected at a threshold of 120 beats/min; none of lesser amplitude were detected. At a baseline rate of 140 beats/min, considered the average heart rate, only half of the decelerations of 50 beats/min were detected at a threshold of 100 beats/min; none of lesser amplitude were detected.

In a controlled trial comparing auscultation with no auscultation in 1951, Walker[14] failed to show any relationship between auscultated FHR and neonatal outcome. In this paper, the author also summarized the published contradictions of auscultatory criteria of fetal distress. A study by Benson et al.[15] involving over 25,000 patients concluded that intermittent auscultation of the FHR was of no demonstrable value in the prediction of early fetal distress. Williams' textbook[16] discusses the limitations of this auscultatory approach (counting begun 30 seconds after the contraction), a feature that had little impact on accuracy in this study, but fails to cite evidence affirming the hypothesis that auscultation improves fetal outcome by the early detection of fetal distress. Apparently paradoxically, several studies have concluded that auscultatory signs of fetal distress are not a risk factor for poor outcome.[17, 18] Data from The Collaborative Project found a greater incidence of low Apgar scores among patients in dysfunctional labor than among those with fetal distress.[18] Neither the American College of Obstetricians and Gynecologists and American Academy of Pediatrics guidelines nor Williams' textbook defines features of auscultation such as the duration of counting, the critical levels for intervention, or the establishment of baseline rate.

Table V. Deviation in detected rate according to duration of count and counting error

Duration of count (sec)	*Error (± beats/min)*	
	1 Beat	*2 Beats*
10	6	12
15	4	8
20	3	6
30	2	4
40	1.5	3
50	1.2	2.4
60	1	2

We will not comment further here on the benefits of auscultation and electronic fetal monitoring. We only wish to remind the reader that auscultation has not been subjected to the same critical review as has electronic fetal monitoring. Perhaps a more scrupulous approach to the acquisition of auscultatory data would improve this situation.

Successive pregnancies complicated by idiopathic sideroblastic anemia

John R. Barton, MD, David C. Shaver, MD, and Baha M. Sibai, MD

Memphis, Tennessee

Sideroblastic anemias are a diverse group of hypoproliferative anemias characterized by defective iron use within erythropoietic cells and a defect in heme biosynthesis. This report describes the first case of successive pregnancies in a patient with idiopathic sideroblastic anemia. Periodic transfusions with washed erythrocytes and oral pyridoxine resulted in normal maternal and perinatal outcome. (AM J OBSTET GYNECOL 1992;166:576-7.)

Key words: Sideroblastic anemia, pregnancy, pyridoxine

Sideroblastic anemia is a descriptive term for a diverse group of disorders that have in common a defect in heme biosynthesis and defective iron use within erythropoietic cells. A sideroblast is a marrow erythroid precursor (specifically, a normoblast) that has Prussian blue–positive granules within the cytoplasm. The granules represent deposits of iron phosphate within mitochondria, which have not been used for heme synthesis. The abnormal accumulation may form a perinuclear ring of iron. This ringed sideroblast is the hallmark of sideroblastic anemia.[1]

Sideroblastic anemia may be hereditary or acquired. Both sex-linked and autosomal recessive patterns of inheritance have been described. The acquired variety of sideroblastic anemia has been associated with certain diseases (especially malignant and inflammatory disorders) and some drugs or toxins (especially ethyl alcohol, lead, isonicotinic acid).[2] There is also an idiopathic variety of sideroblastic anemia.

Sideroblastic anemia is an exceedingly unusual complication of pregnancy. Because of our inability to identify a report of successive pregnancies associated with idiopathic sideroblastic anemia, the management of the following patient is presented.

Case report

A 22-year-old black woman, gravida 2, para 1, was seen at 10 weeks' gestation. Two years earlier, prenatal evaluation had revealed severe anemia. At that time, the hemoglobin was 5.8 gm/dl and hematocrit 19.1%. There were 2,010,000 erythrocytes and 310,000 platelets per cubic millimeter. Reticulocytes were 0.7%. Leukocytes and platelets were normal. Smear of peripheral blood revealed a mixture of normocytic-normochromic cells and hypochromic-microcytic erythrocytes. Anisocytosis, poikilocytosis, target cells, schistocytes, microcytes, and rare basophilic stippling were demonstrated. There were no Pappenheimer bodies.

On bone marrow biopsy, the marrow-to-fat ratio was 70:30. Red blood cells showed erythroid hyperplasia

6/1/33386

with increased numbers of prorubricytes and rubricytes. Progressive hemoglobinization was seen. Special stains for iron showed a marked increase in sideroblasts. The majority of sideroblasts demonstrated perinuclear ring distribution of coarse granules. There was no other abnormality.

The diagnosis was sideroblastic anemia. There was no hereditary predisposition, drug-toxin exposure, and no associated disease. The anemia did not respond to pyridoxine therapy (50 mg daily). Intermittently, the patient required transfusions of washed erythrocytes to maintain the hemoglobin in the 9 to 10 gm/dl range. She experienced spontaneous onset of labor at term but required cesarean section for cephalopelvic disproportion. Transfusion was necessary at the time of surgery. The postoperative course was uneventful. Three weeks after surgery, the hemoglobin was 7.9 gm/dl and hematocrit 19%. She was lost to follow-up until 3 months post partum. At that time, the hematocrit was 11.2%, and again she required transfusions.

The patient used no form of contraception and failed to keep appointments until she suspected pregnancy. When seen at 10 weeks' gestation in the subsequent pregnancy, hemoglobin was 4.7 gm/dl and hematocrit 13.4%. She was transfused with two units of washed erythrocytes and begun on 200 mg pyridoxine daily and 2 mg folate daily. The pregnancy proceeded in an uneventful fashion except for the requirement of intermittent transfusions. Antepartum evaluation of fetal well-being with serial ultrasonography and nonstress testing were normal. There was never any evidence of antibody production as a result of the repeated blood transfusions. After the spontaneous onset of labor at 37 weeks' gestation, a repeat cesarean section and tubal sterilization were performed. The female infant weighed 2296 gm with Apgar scores of 9 and 9. There were no complications. Postoperative hematocrit was 29.5%.

Comment

Anemia is frequently encountered in pregnancy. On occasion, a chronic anemia will require bone marrow analysis. The finding of ringed sideroblasts is diagnostic of sideroblastic anemia. This report demonstrates one patient with idiopathic sideroblastic anemia who was managed successfully throughout two pregnancies by periodic transfusions of washed erythrocytes and oral pyridoxine therapy.

Management is directed toward maintenance of the hematocrit by periodic transfusions of washed erythrocytes. Obvious potential complications include isoimmunization and viral infections. Although only a minority of patients with idiopathic sideroblastic anemia respond to pyridoxine, patients should be treated with 100 to 200 mg of pyridoxine per day (about 100 times the physiologic daily requirement). Further, oral folate supplementation (1 to 2 mg per day) is recommended because concomitant folate deficiency is frequent with idiopathic sideroblastic anemia. Because sideroblastic anemia is allied with myelodysplastic syndromes, patients should also be monitored for the development of acute leukemia.

Dysmenorrhea and use of oral contraceptives in adolescent women attending a family planning clinic

J. Courtland Robinson, MD,[a] Stacey Plichta, BA,[b] Carol S. Weisman, PhD,[b] Constance A. Nathanson, PhD,[b] and Margaret Ensminger, PhD[b]

Baltimore, Maryland

OBJECTIVES: This study examined the prevalance of dysmenorrhea in female adolescents and the effect of experiencing a reduction in dysmenorrhea on oral contraceptive use.

STUDY DESIGN: This was a prospective panel study in which 308 adolescent women at an inner-city family planning clinic were interviewed about their experiences with dysmenorrhea and their oral contraceptive use at three points in time over a 6-month period. A χ^2 test and multiple logistic regression analysis were done.

RESULTS: The overall prevalence of dysmenorrhea in this population was 79.6%; 18.2% reported severe dysmenorrhea. Those who had severe dysmenorrhea and also experienced the reduction of dysmenorrhea as a result of oral contraceptives were eight times more likely to be consistent oral contraceptive users ($p \leq 0.02$).

CONCLUSIONS: It is important to screen female adolescents for dysmenorrhea, provide them with information about the beneficial side effects of oral contraceptives, and follow up these young women to make sure they are experiencing the alleviation of their symptoms. (Am J Obstet Gynecol 1992;166: 578-83.)

Key words: Dysmenorrhea, oral contraceptives, adolescents

Factors influencing effective oral contraceptive use among young women, and in particular adolescents, have been extensively researched. Age, degree of sexual activity, adverse effects, and attitudes of clinic personnel have all been examined, and varying degrees of impact have been ascribed. Missing, for unknown reasons, is the impact of dysmenorrhea. Primary dysmenorrhea is an important clinical and social problem affecting more than 50% of menstruating women.[1] Factors associated with and influencing this problem have been carefully reported in a study of over 600 young women at age 19 and again in the same women at age 24.[2-4] Time, parity, and the use of oral contraceptives were found to be associated with reduction in pain and improved physical and mental attitude. The beneficial impact of oral contraceptives is well established.[4-6] It was the reverse question (does reduction of dysmenorrhea favorably influence oral contraceptive use?) which prompted the inclusion, in a recent study of adolescents' contraceptive use, of an investigation of dysmenorrhea.

This paper reports the results of an analysis of the impact of dysmenorrhea and the experienced reduction of dysmenorrhea on oral contraceptive use over a 6-month period in a panel of adolescent clients of an inner-city family planning clinic.

Material and methods

Subjects. The data for this analysis are from a three-wave panel study of female adolescents who obtained prescriptions for oral contraceptives at a Planned Parenthood clinic in Baltimore during 1988. These women underwent follow-up for 6 months regardless of any return visits to the clinic. At baseline, 430 women were enrolled in the study and interviewed immediately after the clinic visit. Eligibility was limited to those aged ≤18 years who were unmarried, not pregnant, and attending the clinic for purposes of initiating contraception (in some cases after an abortion). The enrolled subjects were 72% of all those eligible during 1988. The major reason for refusing to participate at baseline was reluctance to spend additional time in the clinic. There were no differences in participation rates by age or reason for clinic visit.

Two follow-up interviews were conducted by telephone 3 and 6 months after each subject's baseline interview. Eighty-nine percent (n = 382) of baseline respondents completed both follow-up interviews, and there were no differences in completion rates by age, race, or reason for the initial clinic visit. The major reason for attrition was failure to locate the respondent.

This analysis focuses on a subset of the panel (n = 308) who reported at least one instance of sexual

Table I. Verbal scoring system for assessment of severity of dysmenorrhea*

Severity	*Sometimes or always experience cramps*	*Cramps are very painful*	*Sometimes or always cut back on activities*
No dysmenorrhea	No	No	No
Mild dysmenorrhea	Yes	No	No
Moderate dysmenorrhea	Yes	Yes	No
Severe dysmenorrhea	Yes	Yes	Yes

*The questions used in constructing this scale are: (1) How often do you usually get cramps while you are having your menstrual period—always, sometimes, or never? (2) Would you describe these cramps as very painful or a little painful? (3) On the days when you are having your period, how often do you cut back on your regular activities like staying home from school or staying away from work? Would you say always, sometimes, or never?

intercourse during the follow-up period. These subjects were primarily black (77%), resided in Baltimore City (89%), and were 16 years old on average. Twenty-two percent of them had mothers who were not high school graduates, 58% had mothers who were themselves teenage mothers, and 39% lived with both their mother and a father or stepfather.

For those subjects who had initiated sexual activity by baseline ($n = 293$), the mean age at first intercourse was 14.5 years, and they had an average of 2.9 sex partners. Pregnancy was not uncommon; 58% had been pregnant and 12% had given birth. In general, these subjects are typical of an inner-city population in which sexual activity is initiated at a relatively young age and teenage pregnancy is prevalent.

The interviews were conducted by female interviewers employed by Survey Research Associates, Inc., and not affiliated with the clinic. The baseline interview included questions about sexual and contraceptive history, including ones about the severity and frequency of dysmenorrhea. The two follow-up interviews contained detailed questions about instances of vaginal sexual intercourse and contraceptive use. Additionally, each respondents' clinic record was abstracted at the end of her 6-month follow-up period to obtain information on return visits to the clinic and pregnancies.

Statistical methods. Significance tests for relationship between the severity of dysmenorrhea and subject characteristics and sexual, contraceptive, and health behaviors were calculated with the χ^2 test. The change in odds of being a consistent oral contraceptive user for each variable considered was calculated with multiple logistic regression. The improvement χ^2 test was used to determine the significance of individual predictors in the regression model.

Dependent variable. The dependent variable in this analysis is consistency of oral contraceptive use during the 6-month follow-up period, as reported by the respondent in the follow-up interviews. An extensive discussion of this measure has been reported elsewhere.[7] Briefly, on the basis of information on the date of the index clinic visit, clinic instructions regarding when to start the first package of pills and the respondent's reported pill use (including missed pills), the measure computes the number of days on which each respondent used oral contraceptives divided by the total number of days it was possible for her to have taken oral contraceptives. On average, subjects used oral contraceptives on 65% of possible pill days during the follow-up period; nine subjects never initiated oral contraceptive use, and 19 subjects reported perfect oral contraceptive use.

Because the measure of oral contraceptive use was skewed toward perfect use, it was dichotomized for analysis on the basis of clinical significance of missed pills, according to clinic protocol.[8] Subjects missing three or fewer pills per pack were classified as consistent pill users (38% of all subjects) and those missing more than three pills per pack were classified as inconsistent users (62% of all subjects).

Validation for the dichotomized measure of consistent oral contraceptive use was confirmed by significant associations with several criterion variables. Compared with inconsistent oral contraceptive users, consistent users had significantly more return visits to the clinic for additional prescriptions (58% vs 40%, $p \leq 0.05$), significantly fewer acts of unprotected intercourse (2% vs 39%, $p \leq 0.05$), significantly fewer pregnancy scares (20% vs 33%, $p \leq 0.05$), and fewer pregnancies (6% vs 12%, $p \leq 0.08$).

Dysmenorrhea severity scale. The scale used in this analysis to measure the severity of dysmenorrhea is based on the one created by Andresch and Milsom[2] in a study of 19-year-old women. It ranks the severity of dysmenorrhea using information on how often the women experiences menstrual cramps, how painful she perceives them to be, and how often she cuts back on activities because of them (Table I). This information was gathered at the baseline interview and refers to the time period before oral contraceptive use was initiated and, for the postabortion patients, before the pregnancy resulting in the abortion at the index visit. The main difference between this scale and the Andresch and Milsom scale is that this one does not incorporate the use of analgesics as part of the measure.

Experiencing any reduction in severe dysmenorrhea due to oral contraceptive use was hypothesized to be related to consistent use of oral contraceptives. It was measured by asking respondents about positive side effects of oral contraceptives during the first 3 months

Table II. Prevalence and severity of dysmenorrhea in female adolescents attending a family planning clinic (n = 308)

Severity	*Score*	*n*	*%*	*Cumulative percent, any dysmenorrhea*
No dysmenorrhea	0	63	20.5	0
Mild dysmenorrhea	1	141	45.8	45.8
Moderate dysmenorrhea	2	48	15.6	61.4
Severe dysmenorrhea	3	56	18.2	79.6

Return clinic visit§	33.3	46.8	60.4	48.2	46.4	0.04
Called clinic during follow-up	25.4	30.5	33.3	25.0	28.9	0.70
Drink alcohol once a month or more	15.9	24.8	22.9	19.6	21.8	0.52
Smoke once a month or more	12.7	22.0	18.8	32.1	21.1	0.08

*A count of the instances of vaginal intercourse reported was dichotomized at the mean (mean = 24 acts or an average of once a week).

†Subjects were asked at baseline how they felt about having intercourse. Responses were on a five-point scale, ranging from very unhappy to very happy.

‡Subjects were asked at baseline if they ever experienced pain during intercourse, and if so how often it occurred. Responses were "almost never hurts," "sometimes hurts," "almost always hurts."

§This is a return visit, to obtain oral contraceptives, to the same clinic where oral contraceptives were initially obtained.

of use and combining this information with their baseline reports of dysmenorrhea. Positive side effects measured in the first follow-up interview were reduced menstrual cramping and reduced menstrual bleeding; those experiencing either one or both of these (66% of subjects) were coded as having positive side effects of oral contraceptives. Experienced reduction of dysmenorrhea was calculated as an interaction term between having severe dysmenorrhea and experiencing positive side effects during the first 3 months of oral contraceptive use. Subjects were counted as experiencing a reduction in dysmenorrhea if they had both severe dysmenorrhea and experienced positive side effects (12.7% of subjects).

The analysis also reports associations between dysmenorrhea and other variables relevant to dysmenorrhea and oral contraceptive use. (These variables, including sociodemographic factors, sexual history, and health behaviors, are listed in Table III).

Results

The overall prevalence of dysmenorrhea in this population was 79.6%; 45.3% (141 subjects) reported mild dysmenorrhea, 15.6% (48) reported moderate dysmenorrhea, and 18.2% (56) reported severe dysmenorrhea (Table II). These figures are similar to those reported by Andresch and Milsom[2]; the overall prevalence is somewhat lower than that found in a study of 88 adolescent females.[9]

The relationship between subject characteristics and severity of dysmenorrhea are displayed in Table III. There were no significant differences by age, race, or mother's education. Previous literature suggested that parity (parous vs nonparous) would be negatively

Table IV. Multiple logistic regression analysis of predictors of consistent oral contraceptive use*

Predictor	*Regression coefficient*	*Standard error*	*Relative odds†*	*p Value*
Severe dysmenorrhea	−1.250	0.821	0.29	0.13
Experience one or more positive side effects	0.297	0.300	1.35	0.32

Started menstruation before age 12	−0.113	0.274	0.89	0.68
Smoke cigarettes at least once a month	−0.602	0.343	0.55	0.08
Intercourse once a week or more	0.463	0.273	1.59	0.09
Sometimes or always have painful intercourse	−0.368	0.293	0.69	0.21
Return visit to clinic	0.500	0.255	1.65	0.05

*All coefficients are adjusted for age, race, and mother's education.

†This is the antilog of the regression coefficient. It shows the expected change in odds of the outcome corresponding to a unit change in the predictor.

related to dysmenorrhea and that early onset of menstruation would be positively related to dysmenorrhea.[2, 10] Early onset of menstruation was marginally significant ($p \leq 0.07$); those who began menstruating before age 12 were somewhat more likely to have dysmenorrhea. Parity was the only subject characteristic that was significant ($p \leq 0.03$). Those who were parous before baseline were less likely to report any degree of dysmenorrhea.

Table III also presents information on the relationship of dysmenorrhea to contraceptive and sexual behaviors. In these bivariate analyses, dysmenorrhea was not significantly related to consistent oral contraceptive use or to experiencing less cramping or less bleeding during menstruation. It is of clinical interest that 30.4% of those with severe dysmenorrhea experienced neither of these positive side effects of oral contraceptives.

Also notable is that the severity of dysmenorrhea was significantly associated with sometimes or always experiencing dyspareunia. Experiencing painful intercourse at least some of the time was reported by 14.3% of those without dysmenorrhea, 27% of those with mild dysmenorrhea, 29.2% of those with moderate dysmenorrhea, and 37.5% of those with severe dysmenorrhea. Although intercourse appears to be painful for a significant percentage of women with a dysmenorrhea, the latter subjects are just as likely to report having frequent intercourse (once a week or more) and to report being somewhat or very happy about having intercourse.

Table III also presents the relationship of dysmenorrhea to a set of health behaviors. Those with any degree of dysmenorrhea are significantly more likely to return to the clinic where they initially received the pills over the 6-month follow-up period, although they are no more likely to call the clinic for advice during this time.

The relationship of dysmenorrhea to cigarette and alcohol use was also explored. On the basis of previous findings, it was hypothesized that there would be a positive relationship between dysmenorrhea and alcohol use[10] and a relationship, although the literature has been mixed on the direction, with cigarette use.[2, 3, 10] Although no significant association between alcohol use and severity of dysmenorrhea was found, there was a positive and marginally significant association with cigarette use ($p \leq 0.08$).

A multiple logistic regression analysis was used to examine the effects of severe dysmenorrhea, experiencing positive side effects of oral contraceptives, and an interaction term that represents experiencing a reduction of dysmenorrhea as a result of oral contraceptive use on consistent oral contraceptive use. The analysis controlled for variables that were potentially related to dysmenorrhea or oral contraceptive use. Three sociodemographic variables were included as covariates: age, race, and mother's education (a proxy for socioeconomic status). Previous research suggested that older adolescents, whites, and those with higher socioeconomic status are more compliant with contraception.[11-14]

The results of this analysis appear in Table IV. The most statistically and clinically significant predictor of consistent oral contraceptive use was experiencing the reduction of dysmenorrhea as a result of oral contraceptive use; those with severe dysmenorrhea who reported positive side effects of the pill were eight times as likely to be consistent oral contraceptive users as others ($p \leq 0.02$). The only other statistically significant predictor of oral contraceptive use was returning to the same clinic for oral contraceptives (1.65 times as likely, $p \leq 0.05$)

Two predictors, tobacco smoking and frequency of

intercourse, were marginally significant. Those who smoked cigarettes at least once a month were about half as likely (0.55, $p \leq 0.08$) to be consistent oral contraceptive users. Those who had intercourse at least once a week were 1.59 times more likely to be consistent oral contraceptive users ($p \leq 0.09$). Other studies have reported similar findings. Frequency of intercourse was thought to increase the perceived risk of pregnancy, and thus those with more frequent intercourse would be expected to be more consistent oral contraceptive users.[15-17]

Comment

This analysis demonstrates that an important predictor of consistent oral contraceptive use among adolescent women attending an inner-city family planning clinic was experiencing the alleviation of dysmenorrhea during the first 3 months of oral contraceptive use. Both this finding and the finding of a high prevalence of dysmenorrhea in the adolescent population underscore the importance of screening for dysmenorrhea all women who are seen at family planning clinics. This screen can be as straightforward as the three-question scale used in this analysis, with further probing if a woman responds positively to these questions.

Adolescents are often poorly informed about menstrual events. One study[18] reported finding substantial ignorance and misinformation among female adolescents regarding the causes and treatment of dysmenorrhea. Once it is determined that an adolescent suffers from dysmenorrhea, it is important to presensitize her to the potential positive side effects of oral contraceptives. Many clinics routinely stress the negative side effects of oral contraceptives without giving similar emphasis to the positive ones. Without adequate information, an adolescent woman with dysmenorrhea may not connect the relief of her symptoms to consistent oral contraceptive use, nor might she use oral contraceptives long enough to experience relief.

It is also important to follow up on women with dysmenorrhea to determine if they are experiencing alleviation of their symptoms. Fully 30.5% of the women with severe dysmenorrhea did not perceive experiencing any positive side effects of oral contraceptives. Having severe dysmenorrhea alone was not predictive of oral contraceptive use.

Consistency of care, as measured by a return visit to the clinic, is important in the provision of health care to adolescent women. It was significantly and positively related to both having dysmenorrhea at baseline and using oral contraceptives consistently over the follow-up period. This implies that clinics should encourage their clients to return to the same site for care.

This analysis also found several other health problems that were significantly related to dysmenorrhea. The prevalence of dyspareunia is so high in this population that it is important for clinicians to ask about dyspareunia and to provide information on how to alleviate it. It is apparent that reproductive health care for adolescents needs to include an open and thorough discussion about sexual functioning.

There was also a positive association between the severity of dysmenorrhea and smoking. Although the findings in the literature are mixed, one possibility is that adolescents with dysmenorrhea use cigarette smoking in an attempt to alleviate symptoms. If this is the case, it is vital that clinicians counsel these women on the health risks inherent in smoking and on alternate ways to relieve symptoms (such as consistent oral contraceptive or analgesic use).

Although this study had several findings relevant to understanding dysmenorrhea and oral contraceptive use in female adolescents, it does have some limitations which need to be noted. The major limitation is that the population consisted of female adolescents who were motivated to seek contraception; they may not be representative of all sexually active adolescents or of all adolescents with dysmenorrhea. Another limitation is that the subjects were all recruited in one family planning clinic and may not be representative of all adolescents who seek contraceptive services.

There have been few studies of the effect of dysmenorrhea on health behavior in female adolescents. A replication of this study is needed to confirm some of the findings and to further explore the relationship between dysmenorrhea, sexual health, and contraceptive use.

We thank the clients, staff, and administrators of the Planned Parenthood clinic from which the respondents were recruited.

Nonsurgical management of penetrating uterine trauma in pregnancy: A case report

Debra K. Grubb, MD
Los Angeles, California

A woman at 30 weeks' gestation with stab wounds entering the uterus was managed nonsurgically by serial examinations and continuous fetal monitoring. Delivery occurred 4 weeks later with good maternal and fetal outcome. (AM J OBSTET GYNECOL 1992;166:583-4.)

Key words: Abdominal injuries, pregnancy, stab wounds

Penetrating abdominal trauma is an uncommon complication of pregnancy, with gunshot wounds much more common than stab wounds.[1] We report a case of multiple stab wounds to the abdomen of a pregnant woman, with documented penetration of the uterus, which was managed nonsurgically with a good outcome.

Case report

A 26-year-old Hispanic woman at 30 weeks of gestation in her first pregnancy was brought to the hospital by ambulance after her husband inflicted multiple stab wounds to the abdomen and upper extremities with a steak knife. On admission, the patient was hemodynamically stable and the fetal heart rate was 140 beats/min. Stab wounds to the hands, right upper arm, and abdomen were cleaned and dressed. Obstetric ultrasonography revealed a single fetus in a breech presentation, with an estimated fetal weight of 1928 gm and no evidence of fetal injury. The fetal head was directly below one of the wounds. There was a normal amniotic fluid volume, and the placenta was anterior with no evidence of retroplacental blood clot. Continuous fetal heart rate monitoring, serial hematocrit determinations, and serial abdominal examinations were undertaken. A Kleihauer-Betke test for fetal erythrocytes was negative. An amniocentesis was performed to rule out amnionitis. The amniotic fluid was grossly bloody, but Gram stain and subsequent culture did not reveal any organisms. The hematocrit was stable over 24 hours at 30%, the fetal heart rate was reactive without decelerations, and no signs of peritonitis developed. The patient was then observed in the hospital for an additional 48 hours. No signs of infection developed, and she was discharged from the hospital.

In the obstetrics clinic, there were normal heart tones and her wounds were healing well. At 34 weeks of

6/1/33027

gestation, she was admitted to the hospital in labor. The cervix was completely effaced and 4 cm dilated, and the fetus was in a transverse lie. Fetal heart rate monitoring was normal. External version to the vertex position was performed without difficulty. On rupture of the membranes, the fluid was noted to be dark brown with particulate matter present. The first stage of labor lasted 9½ hours and required oxytocin augmentation. The second stage of labor lasted 1 hour. A vigorous female infant weighing 2540 gm with Apgar scores of 8 at 1 minute and 8 at 5 minutes was delivered spontaneously. The uterus was explored manually and was intact.

The infant had a clinical estimation of gestational age of 35 weeks. The peripheral hematocrit at birth was 60% and was stable. A poorly healed laceration about 5 mm long that was noted over the infant's left parietal bone closed spontaneously on the second day of life.

Comment

Evaluation of the pregnant patient with either gunshot or stab wounds of the abdomen must take into consideration the physiologic changes of pregnancy while following the principles of trauma management. Pregnant women have an increased tolerance to blood loss because of their increased blood volume and are also less likely to have guarding and rigidity with peritoneal irritation. Although a patient with a gunshot wound generally requires surgical exploration, a patient with a stab wound to the abdomen may require exploratory laparotomy only if there is evidence of intraperitoneal hemorrhage or bowel perforation.[2] Cesarean section may be required if fetal distress ensues. The decision to deliver the fetus is frequently complicated by fetal prematurity and the difficulty in determining the extent and likelihood of repair of the fetal injury.

In this patient grossly bloody amniotic fluid suggested that the peritoneal cavity and uterus had been penetrated. Because there was no evidence of maternal or fetal hemorrhage or bowel injury, exploratory laparotomy was deferred. It seems unlikely, in view of the injury noted at delivery, that earlier delivery would have improved the outcome of the infant in any way. This case supports recommendations in the literature that injuries known to penetrate the uterus may be managed with the fetus left in utero if there is no evidence of fetal distress or amnionitis.

Doppler ultrasonographic features of the developing placental circulation: Correlation with anatomic findings

Eric Jauniaux, MD, Davor Jurkovic, MD, Stuart Campbell, MD, Jean Hustin, MD, PhD
London, England, and Loverval, Belgium

Color Doppler was used to study the placental circulations of 28 pregnancies between 10 and 17 weeks' gestation. A histomorphometric investigation was performed on placental tissue samples from those pregnancies, and the results were compared with Doppler features. Important changes were found around 14 weeks' gestation in both uterine and umbilical circulations. The appearance of end-diastolic frequencies in the umbilical arteries was related to an abrupt and significant ($p < 0.005$) increase in uterine velocity and to the establishment of a continuous intervillous circulation. (Am J Obstet Gynecol 1992;166:585-7.)

Key words: Doppler ultrasonography, placental circulation, early pregnancy

The beginning of fetal life is associated with remarkable hemodynamic changes in the placental circulations. During the first 3 months of gestation, the growing embryo is separated from the maternal circulation by the trophoblastic shell.[1] The tips of the spiral arteries are obstructed by intravascular trophoblastic plugs, and the intervillous space is bathed by a clear fluid, possibly made of filtered plasma and uterine gland secretions. The spiral arteries widen progressively, and around 12 weeks' gestation the trophoblastic plugs are eventually loosened and dislocated, allowing free blood circulation in the intervillous space.[1]

The purpose of this study was to investigate Doppler flow velocity waveform characteristics in the placental circulation between 10 and 17 weeks' gestation and to correlate these with anatomic features of placental vascular development.

Material and methods

Twenty-eight pregnant women between 10 and 17 weeks' gestation were investigated, four cases for each gestational week between 12 and 15 weeks and three for each of the other weeks. All were referred for ultrasonographic examination before termination of pregnancy for psychosocial reasons. Only patients who were certain of their last menstrual period, who were not using oral contraceptives, and who had never smoked were included in the study. All pregnancies were clinically uncomplicated, and ultrasonographic measurement of crown-rump length or biparietal diameter was within the normal range for gestational age.

After giving informed consent, each woman underwent Doppler examination with 5.0 MHz curvilinear transvaginal probe with pulsed and color Doppler facilities (Aloka Color Doppler SSD-680, Aloka Co., Tokyo). The high-pass filter was set on 100 Hz and the pulse repetition frequency was 2 to 12 kHz. Color Doppler was used to identify vessels of interest and served as a guide for pulsed Doppler velocimetry studies. In each case flow velocity waveforms were obtained from both main uterine arteries at the level of the internal os, from spiral arteries at the level of the placental bed, and from umbilical cord arteries. The intraplacental areas of color flow were also investigated by spectral Doppler analysis. Simultaneous color imaging made it possible to obtain the maximum peak velocity in the uterine artery by positioning the transducer so that the angle between the pulsed Doppler beam and the vessel was close to zero. Uterine flow velocity waveforms were standardized by means of the resistance index, calculated as the mean obtained from three waveforms of satisfactory quality and averaged for both sides.

Terminations of pregnancy were performed within 2 hours after Doppler ultrasonographic investigations. In each case samples of placental tissue were obtained by aspiration and were immediately immersed in formalin. After 3 days of fixation the specimens were embedded in paraffin, sectioned at 4 μm intervals, and stained with hematoxylin and eosin for histologic examination. The sections were viewed with an immersion objective, connected to a video system. Twenty normally trophic, stem villi were examined at random for each case. A point-counting grid was superimposed onto the image, and the fraction of the villous surface (percent) occupied by the fetal vessels was estimated by test point counting. The number of vessel profiles per villous profile was also calculated.

The relationships between gestational age and Doppler and histologic data were analyzed by simple regres-

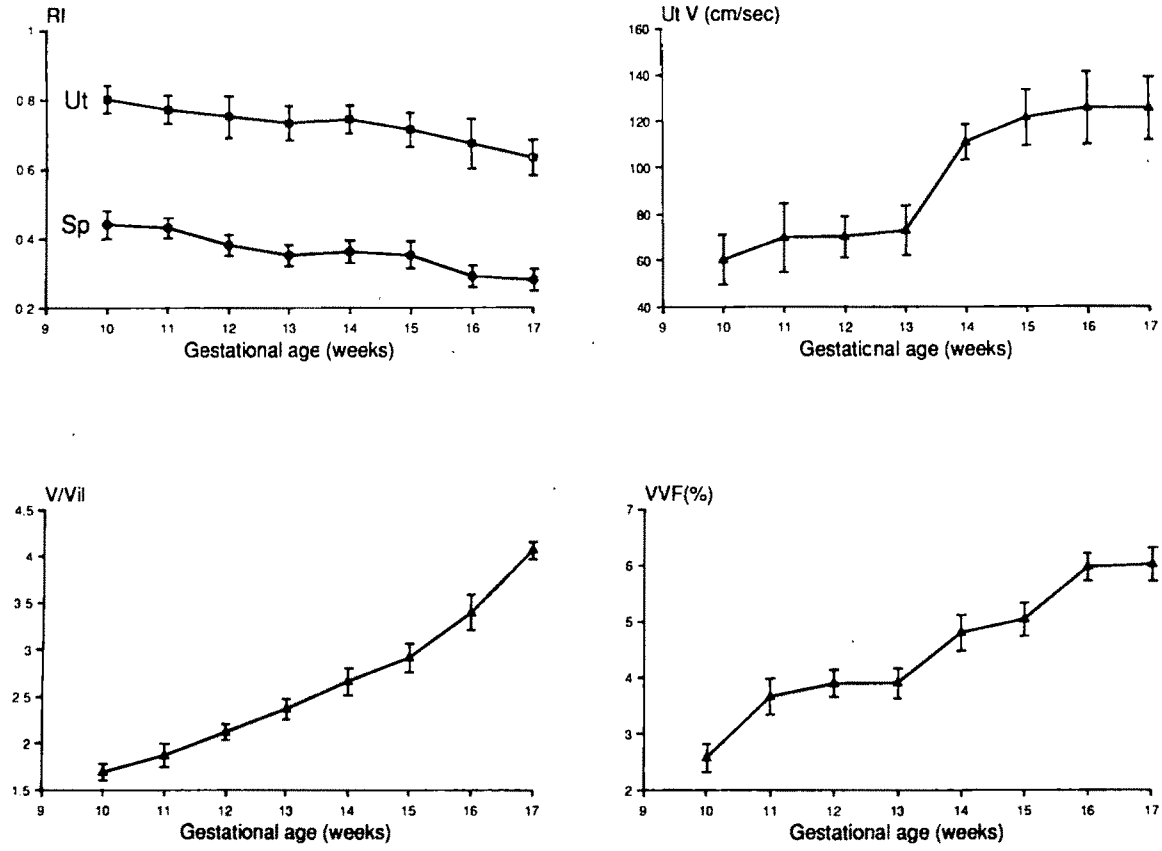

Fig. 1. Mean values (±SEM) per week for uterine *(Ut)* and spiral *(Sp)* resistance index *(RI)*, uterine peak velocity *(UtV)*, number of vessels per villous profile *(V/Vil)*, and vascular volume fraction *(VVF)*.

sion models. Where appropriate, significant differences were calculated by the Kruskal-Wallis rank test.

Results

The main uterine, spiral, and umbilical cord arteries were visualized by color Doppler in all cases. The best regression fit between gestational age and each parameter was observed to be linear for uterine resistance index ($r = -0.38$, $n = 28$, $p < 0.05$, $a = 0.96$, $b = -0.02$, SEM = 0.09) and spiral resistance index ($r = -0.61$, $n = 28$, $p < 0.001$, $a = 0.61$, $b = 0.02$, SEM = 0.05) and exponential for uterine peak systolic velocity ($r = 0.74$, $n = 28$, $p < 0.001$, $a = 2.86$, $b = 0.12$, SEM = 0.25), number of vessel profiles per villous profile ($r = 0.93$, $n = 28$, $p < 0.001$, $a = -0.66$, $b = 0.12$, SEM = 0.1), and vascular villous fraction ($r = 0.84$, $n = 28$, $p < 0.001$, $a = 0.03$, $b = 0.1$, SEM = 0.16).

Fig. 1 shows the results expressed as a mean (±SEM) for week of gestational age for each parameter. Table I summarizes the measurements. Uterine and spiral artery waveforms showed a smooth progressive decrease of resistance index values with gestation. This change was significant before 13 ($p < 0.01$) and after 14 ($p < 0.05$) weeks of gestation for the spiral resistance index only. The mean peak systolic velocity in the uterine artery increased slowly but not significantly with gestation from 10 to 13 weeks. However, during the fourteenth week an abrupt and significant ($p < 0.005$) increase in peak systolic velocity was observed. After that, a slow increase continued until 17 weeks (Fig. 1).

Between 12 and 14 weeks, end-diastolic frequencies in the umbilical artery were incomplete or inconsistently present. At the same time, a nonpulsatile blood flow pattern was detected when the Doppler gate was placed on intraplacental sonolucent spaces. Pandiastolic frequencies in the umbilical artery and continuous venous flow within the placenta were consistently present in all cases later in gestation. The number of vessel profiles per villous profile and the vascular villous fraction increased significantly with gestation (Table I).

Comment

The current study shows that major hemodynamic changes occur in both fetal and maternal placental circulations around 14 weeks of gestation. At that time we observed blood flow with a venous pattern, i.e., intervillous flow within the placenta, an abrupt and sig-

nificant increase of the mean uterine peak systolic velocity (Fig. 1), and the appearance of pandiastolic frequencies in the umbilical arteries.

Theoretically, the resistance to blood flow and the variation in the shape of the flow velocity waveforms reflect changes in the resistance of the distal vascular bed. Previous authors have shown that the appearance of diastolic frequencies in the umbilical arteries of early pregnancy is associated with an abrupt fall of the resistance index in the umbilical artery.[2] We believe that these changes do not reflect a sudden opening of the villous capillaries or a merging between villous and embryonic vessels, as suggested by these authors. Placental angiogenesis starts during the fifth week after the last menstruation, and all specimens that we have investigated had well-formed villous vessels 4 weeks before the appearance of diastolic frequencies. Their number and the surface of stem villi occupied by these vessels increased significantly between 10 and 17 weeks' gestation. Although these progressive anatomic changes in the villous vasculature must have an important role in the gradual fall in the resistance to blood flow in the umbilical circulation, the appearance of end-diastolic frequencies coincided with a significantly higher blood velocity in the main uterine arteries and with the presence of a continuous intervillous flow. The establishment of the intervillous circulation at the beginning of the second trimester of pregnancy may also be associated with changes in the pressure gradient between the uterine circulation and the intervillous space or with alterations in blood gases and metabolites, which could influence the specific properties of the placental vessels and therefore the appearance of end-diastolic frequencies in the umbilical circulation. Longitudinal histomorphometric study of the villous vasculature would be unethical and focal villous sampling would not give a representative picture of the placenta as a whole. However, serial Doppler ultrasonography can be performed to establish more accurately the close relationship that exists between the development of the two placental circulations in early pregnancy.

Routine urine drug screening at the first prenatal visit

Garrett H.C. Colmorgen, MD, Cherie Johnson, MD, Martha A. Zazzarino, RNC, and Karen Durinzi, MD

Wilmington and Newark, Delaware

OBJECTIVE: The purpose of this study is to determine whether routine urine drug screening at the first prenatal visit will identify and permit early intervention for those at risk for poor outcome.

STUDY DESIGN: Comparisons of maternal and neonatal outcomes between 166 randomly chosen patients with positive and 150 randomly chosen patients with negative drug screens identified by the enzyme multiplied immunoassay test were made by unpaired t test, χ^2 test, probit analysis, and tests of independent Poisson distributions.

RESULTS: Forty percent of those identified denied drug use. Antepartum ($p < 0.01$) and postpartum ($p < 0.05$) complications were increased among drug users. Birth weight ($p < 0.001$), gestational age ($p < 0.03$), and head circumference ($p < 0.05$) were decreased among neonates.

CONCLUSION: Because of difficulty in identifying illicit substance–using patients, consideration should be given to the implementation of routine urine drug screening at the first prenatal visit in populations with a high rate of illicit substance use. (Am J Obstet Gynecol 1992;166:588-90.)

Key words: Drug screening, prenatal care, substance abuse

Complications from illicit drug use during pregnancy have increased at an alarming rate. Substance abuse has been associated with low birth weight, premature deliveries, and sexually transmitted diseases.[1, 2] Since 1985 we have noticed an increase in illicit substance use among pregnant women registered for prenatal care through the Outpatient Services Department of the Wilmington Hospital of the Medical Center of Delaware. To identify patients at risk for complications of pregnancy associated with substance abuse, we began performing routine urine drug screening at the first prenatal visit. We offer counseling and special services to patients with urine drug screens positive for illicit drug use in an effort to decrease the potential risks to mother and child.

The purpose of this study was to evaluate the role of urine drug screening as a component of routine prenatal care. Specifically, we sought to determine if urine drug screening is an effective method of identifying those women who will benefit from drug counseling and supportive services.

Material and methods

Although a careful history is performed by both nurses and physicians at the first prenatal visit, self-reporting of drug use is of limited accuracy. Thus all patients registered for prenatal care through the Outpatient Services Department (teaching service) of the Wilmington Hospital routinely submit a urine sample for screening by the enzyme multiplied immunoassay test to determine the presence of cannabinoids, cocaine, opiates, barbiturates, amphetamines, and benzodiazepines. Positive results are confirmed by means of thin-layer chromatography, gas chromatography, and gas chromatography–mass spectrophotometry as appropriate for the presence of specific substances. Patients are informed of drug testing by a pamphlet that describes laboratory procedures performed during pregnancy.

From July 1, 1988, through June 30, 1989, approximately 6700 women were delivered at the Medical Center of Delaware. Of these, 1088 women registered through the Outpatient Services Department (teaching service) were delivered. Those with a positive drug screen ($n = 166$) were compared with a sample of 150 patients selected by means of a random number table from the remainder of the population for whom the initial drug screen was negative. Patients who admitted alcohol use were screened by serum testing.

We compared outcome criteria (preterm labor, bleeding during pregnancy, premature rupture of the membranes, hepatitis, human immunodeficiency virus infection, delivery method, gestational age at delivery, twinning, fetal monitor problems, antepartum and postpartum complications, birth weight, Apgar scores, malformations, head circumference, neonatal withdrawal, neonatal seizures, neonatal tachycardia, neonatal hyperirritability, intraventricular hemorrhage, patent ductus arteriosus, necrotizing enterocolitis, meconium staining, and need for neonatal mechanical ventilation) for substance users versus controls. Unpaired t test, χ^2 test, probit analysis, and tests of in-

dependent Poisson distributions were used for inference.

Results

The substance abusing and control populations were compared with regard to several demographic factors to determine differences between the groups. No significant difference between the study and control populations was found with regard to racial composition (50% black, 45% white, 5% Hispanic [both groups exactly the same]), cigarette use (39% vs 45%), or parity (substance abusers' mean parity = 1.3 vs controls' mean parity of 1.0). A statistical difference was found with regard to age (substance abusers' mean age was 23.9 years vs controls' mean age of 22.1 years [$p < 0.05$]).

The incidence of abuse of one or more drugs was found to be 15.3% among the Outpatient Services Department patients. The drugs used by this population were cocaine ($n = 104$, 62%), marijuana ($n = 100$, 60%), alcohol ($n = 22$, 13%), amphetamines ($n = 10$, 6%), opiates ($n = 10$, 6%), and barbiturates ($n = 6$, 3%). Among substance users, 90 (54%) admitted drug use at the first prenatal visit, 66 (40%) denied drug use, and data for 10 (6%) were not available. The rate of denial of illicit drug use among those women who eventually stopped using drugs (39%) was not significantly different from that of those who continued (41%).

Among maternal outcome criteria, antepartum complications (Table I) and postpartum complications (Table II) were found to be significant ($p < 0.01$ and $p < 0.05$, respectively) when controls were compared with substance users.

Of neonatal outcome criteria, a significant difference between the controls and substance abusers was found for birth weight, gestational age, and head circumference data (Table III). We found no significant differences between the groups with regard to the other outcome criteria studied.

Comment

Among those women in our population who use drugs, we found that approximately 40% denied drug use at the first prenatal visit. Interestingly, this was equally true for the subpopulations that discontinued (39%) and continued (41%) drug use. The failure of patients to report behavior that is inimical to the health of themselves and their fetuses is likely due to complex factors, including social stigma, fear of legal prosecution, and an understanding that they might be coerced into accepting a medical treatment program. Although the population studied is indigent, it is possible that a survey of the private population served by our hospital would have yielded similar results. Chasnoff et al.,[3] in their recent study of substance use in private and clinic populations, have found an incidence of 14.8% among pregnant women, a rate similar to that found in our population. They found no significant difference in the rate of illicit substance use between private and clinic populations. This high rate of substance use in pregnancy places many mothers and fetuses at risk for adverse pregnancy outcomes.

Several authors have reported an increased rate of

Table III. Neonatal outcome

Outcome	*Controls (n = 150)*	*Drug users (n = 166)*	*p*
Birth weight (gm)	3255 ± 632	2905 ± 738	<0.001
Gestational age (wk)	39.0 ± 2.3	37.3 ± 3.5	<0.003
Head circumference (cm)	34.0 ± 1.9	32.7 ± 2.8	<0.05

anemia,[4] preterm labor,[1, 5, 6] abruptio placentae,[6, 7] premature rupture of the membranes,[5] and premature delivery[1, 5, 7, 8] among substance users, especially those who use cocaine. We also found an increased risk of antepartum and postpartum complications when comparing drug users with controls (Tables I and II, respectively).

An increased risk of fetal monitoring abnormalities, meconium staining, and anemia also have been reported as complications of maternal illicit substance use.[4] We found no differences with regard to these parameters between controls and the substance users.

Low birth weight, earlier gestational age at delivery, and smaller head circumference have been described as complications of cocaine[1, 2, 4, 5, 7, 8] and heroin[9] use. Several authors have reported an increased incidence of anomalies among the offspring of pregnant substance users.[1, 4] The rate of anomalies among cocaine abusers has been reported as 5.7%, versus 1.4% among controls.[1] Genitourinary tract[2] and cardiac anomalies[4] have been reported in the infants of these patients. Whether the increase in the rate of anomalies among the infants of substance users is due to exposure to illicit substances or to other factors in the life-styles of their mothers, such as poor nutrition, is unclear.[4] When comparing the neonates of drug users with those of controls in our population, we found no statistical difference in the rate of anomalies.

A key issue in the management of illicit substance use in pregnancy is the identification of the problem. Others have demonstrated that management of these patients in a supportive program can be successful. However, the dangers of our approach to the identification of the patient must be acknowledged. This approach could not be advocated in those states that take a punitive approach to the problems of pregnant drug users. The great danger of routine drug testing is that the state may subpoena this medical information for use in the prosecution of the patient. Obstetrician-gynecologists and their staffs should not be obligated to function as agents for the state.[10]

In some populations illicit drug use may not be as widespread, and routine drug testing may not prove to be a cost-effective method of screening for drug use. Thus we recommend that a blinded survey of the population to be screened be performed before the implementation of routine urine drug testing. Potential problems resulting from drug screening include late entry into prenatal care and the failure to identify those drug using patients who abstain from drug use before their first prenatal visit and resume or begin drug use afterward.

This study found that approximately 40% of pregnant substance users denied drug use. Routine drug screening permitted the identification of these patients. Given the prevalence of maternal illicit substance use in populations such as ours, we propose that consideration be given to the establishment of urine drug screening at the time of the first prenatal visit as a component of routine prenatal care. We recognize that in some populations the knowledge that drug screening is being performed may serve as a deterrent for patients to enter prenatal care. However, if the care provided is nonjudgmental and supportive, we feel that drug screening provides a useful adjunct in the management of pregnancies at high risk for exposure to illicit drugs.

Bilateral choroid plexus cysts in trisomy 21

Siegfried Rotmensch, MD, Jia-Sen Luo, MD, Jose A. Nores, MD, Miriam Schoenfeld Dimaio, MD, and John C. Hobbins, MD

New Haven, Connecticut, and Taipei, Taiwan, Republic of China

Whether karyotyping is indicated in a fetus with choroid plexus cysts who is otherwise structurally normal is still controversial. Many authors have suggested basing the decision on cyst size, bilaterality, persistence with advancing gestational age, and association with other anomalies. We report a case of large bilateral choroid plexus cysts in a fetus with trisomy 21 who had no evidence of congenital anomalies or ultrasonographic signs of Down syndrome. Cyst sizes diminished by half over a 3-week period of follow-up. It appears that diminishing size alone should not be considered sufficient reassurance about the normality of the fetal karyotype. A similar case has been previously reported, and it is conceivable that choroid plexus cysts are associated not only with trisomy 18 but also with trisomy 21. (AM J OBSTET GYNECOL 1992;166:591-2.)

Key words: Choroid plexus cyst, trisomy 21

The prenatal ultrasonographic finding of choroid plexus cysts has been described in fetuses with trisomy 18, as well as in those with normal chromosomes. Whether karyotyping is indicated in a fetus who otherwise appears to be structurally normal has been the subject of much recent debate. Only one case of antenatally diagnosed choroid plexus cysts in a fetus with trisomy 21 has been reported in the literature.[1] This fetus also had an atrioventricular septal defect. We present a case of trisomy 21 in which the only ultrasonographically apparent abnormalities were bilateral choroid plexus cysts.

Case report

A 35-year-old woman, gravida 4, para 3, presented for routine ultrasonographic examination at 16 weeks' gestation, before amniocentesis for karyotyping. Biometric measurements were consistent with gestational age. Gross fetal anatomy appeared normal, except for the presence of bilateral choroid plexus cysts of 10 mm diameter in each atrium of the cerebral ventricles. The four-chamber view of the heart showed no abnormality. The nuchal fold thickness measured 3 mm. The middle phalanx of the fifth digit was equal in size to the middle phalanx of the fourth finger. The expected-to-actual femur length ratio and the biparietal diameter/femur length ratio were within the mean. The maternal serum α-fetoprotein level was within normal limits. An amniocentesis was performed and 16 ml of clear fluid was obtained. The karyotype was 47,XX +21.

The patient was counseled about the implications of the karyotype and decided to terminate the pregnancy at 19 weeks' gestation by dilation and evacuation. A repeat ultrasonographic scan before termination reconfirmed normal fetal anatomy and bilateral choroid plexus cysts, each of which had shrunk to 5 mm in diameter.

Comment

Cysts of the choroid plexus arise from neuroepithelial folds within the choroid plexus and are filled with fluid and cellular debris. They are found frequently on microscopic examination of fetal, newborn, and adult brains. The incidence of macroscopically apparent cysts in chromosomally normal subjects, however, has probably been overestimated because of the use of histologic criteria for the definition of their presence. The estimated incidence of ultrasonographically diagnosed choroid plexus cysts in a population of normal midtrimester fetuses is 0.3%. An association with trisomy 18 has been suggested[2]; however, the magnitude of this link is controversial.

Choroid plexus cysts associated with trisomy 21 have so far been described in the literature in only one case.[1] This fetus also had an atrioventricular septal defect. In our case bilateral choroid plexus cysts were the only abnormal finding in a detailed anatomic survey. Whether the finding was incidental or linked to the chromosomal anomaly is difficult to determine. If such an association is assumed, it is probably not a very consistent one, because multiple series of fetuses with Down syndrome have not reported this finding. However, a review of 98 prenatally diagnosed cases of trisomy 21 in our institution revealed two such cases. Unfortunately, only one case had complete ultrasono-

graphic documentation. Even if the association between cysts of the choroid plexus and trisomy 21 was 1 in 100, most women would still wish to be offered prenatal diagnosis. However, it would require 120,000 midtrimester ultrasonographic scans to demonstrate a prevalence of this magnitude within 95% confidence limits of 0.5% and 1.5%.

It is intriguing that the chorcid plexus cysts in our case displayed multiple characteristics that were associated with a trisomic karyotype by several authors. Chitkara et al.[2] suggested that a cyst diameter >10 mm and a bilateral location, as observed in our case, are more likely associated with a trisomic fetus. This tends to suggest that the finding of choroid plexus cysts in this case was not incidental but was linked to the abnormal karyotype. Interestingly, we observed a 50% decrease in cyst diameter within a 3-week period of follow-up. Therefore diminishing cyst size alone should not be considered sufficient reassurance about the normality of the fetal karyotype. Furthermore, this finding emphasizes that in spite of improved ultrasonographic visualization of anatomy with advancing gestational age early scans can occasionally contribute exclusive information.

Radical hysterectomy in the elderly patient: Analysis of morbidity

Carlos Fuchtner, MD, Alberto Manetta, MD, Joan L. Walker, MD, Dennis Emma, PhD, Michael Berman, MD, and Philip J. DiSaia, MD

Long Beach and Orange, California

OBJECTIVE: This study compares the perioperative morbidity and mortality following radical hysterectomy of patients older than 65 years with a younger age group who underwent radical hysterectomy and pelvic lymphadenectomy for cervical carcinoma stage IB or IIA.

STUDY DESIGN: A retrospective analysis of morbidity and mortality for the first 60 postoperative days was conducted. The study population of 45 women >65 years of age with cervical cancer treated by radical hysterectomy was compared with a control population of 90 women <65 years treated similarly.

RESULTS: In the elderly group, 31 of 45 and 12 of 15 were American Society of Anesthesiologists Physical Status II and III respectively; 68/90 and 19/90 were American Society of Anesthesiologists status I and II in the younger age group ($p = 0.001$). Transfusions of >2 units were required in 14% of the elderly and 35% of younger patients ($p = 0.02$). No statistical differences were observed between groups for other parameters examined.

CONCLUSION: Age alone should not be a contraindication for radical hysterectomy in the elderly patient with American Society of Anesthesiologists Physical Status I to III. (Am J Obstet Gynecol 1992;166:593-7.)

Key words: Geriatric, radical hysterectomy, cervix carcinoma

The controversy between surgical treatment, radical hysterectomy with bilateral pelvic lymphadenectomy, and radiotherapy in the treatment of women with stage IB or IIA cervical carcinoma has existed for decades. Retrospective series of both types of treatments show no significant difference in survival for either regimen.[1] Surgical therapy is preferred in younger women because of the preservation of hormonal function and avoidance of the radiotherapy-related sexual dysfunction.[2]

The advantage of radiotherapy is its applicability to virtually all patients, whereas radical surgery excludes certain medically inoperable cases. Traditionally, operation has been considered to be contraindicated in older women because of unacceptable increases in morbidity and mortality thought to be associated with advanced age and related concomitant disease.

Over the last two decades significant advancements have been made in the medical management of patients undergoing radical surgery. The purpose of this study was to compare the intraoperative and postoperative morbidity and mortality of patients older than 65 years undergoing radical hysterectomy to younger patients undergoing similar treatment.

Material and methods

The study (elderly) population consisted of 45 patients aged ≥65 years who were diagnosed with cervical cancer, stage IB or IIA, and treated with radical hysterectomy and pelvic lymphadenectomy by the Division of Gynecologic Oncology at the University of California, Irvine Medical Center and Long Beach Memorial Medical Center from January 1980 through December 1989. The control (younger) population consisted of the next two patients younger than 65 years with a diagnosis of cancer of the cervix who were admitted for the same operation after a study case admission. Controls were matched to study cases by diagnosis, stage, and type of operation. Cases were identified by the respective institutional tumor registries. Medical records were reviewed for both groups and analyzed for morbidity and mortality for the first 60 postoperative days. Follow-up information was obtained from the tumor registry, patient records, referring physicians, and death certificates.

All patients underwent a radical hysterectomy, Meigs

type 3,[3] and pelvic lymphadenectomy as described by Taussig.[4] Prophylactic antibiotics were used in all cases. The majority of patients received cephalosporin for 24 hours. Prophylactic heparin, 5000 IU given subcutaneously every 12 hours, was used in all patients until 1984. Subsequent patients were treated with pneumatic calf compression. Drains were routinely used and were positioned on the pelvic sidewalls with the exit through stab wound incisions. We used the American Society of Anesthesiologists physical status classification system[5] in determining the potential surgical risks. Surgical infection morbidity was analyzed on the basis of clinical evaluations and cultures and classified according to a modification of the criteria used by Sevin et al.[6] Surgical site–related infection consisted of: (1) sepsis, (2) pelvic abscess or hematoma associated with fever, (3) pelvic cellulitis, (4) wound infection with purulent wound breakdown, or (5) other intraabdominal infections distant from the operative site. Non–surgical site–related infection included: (1) urinary tract infection or (2) postoperative respiratory infection. Morbidity not related to infection included: (1) fever of 38.0° to 39.4° C orally within the first 48 hours (e.g., pulmonary atelectasis), (2) fever of 38.0° C orally on two separate postoperative occasions at least 6 hours apart, >48 hours after the end of the procedure (e.g., no infection identifiable), or (3) sterile wound separation with negative cultures.

Statistical analysis was performed with Pearson χ^2, Student *t* test, and Kolmogorov-Smirnov analysis of categoric data.[7] Life-table analysis was performed with the Kaplan-Meier method[8] and survival functions were compared with the Mantel-Cox model.[9]

Results

The study group consisted of 45 patients, with ages ranging from 65 to 83 years (mean 70.1 ± 4.2), with 15 (33.3%) patients aged ≥70. The 90 patients <65 years old included in the control group ranged in age from 19 to 64 years, (mean 41.7 ± 10.9). The histologic characteristics and stages for the study population and younger control group demonstrate no statistical difference in stage, histologic type, tumor volume, frequency of lymph node metastasis, and the finding of occult parametrial disease (Table I). Poorly differentiated tumors were significantly less frequent in the elderly patient group ($p = 0.008$). A significant difference was found in the anesthetic risk of the study versus control groups. In the geriatric population 31 (68.9%) and 12 (26.7%) patients were American Society of Anesthesiologists class II and class III, respectively, whereas in the younger group 75.8% and 20.9% were class I and class II, respectively ($p = 0.001$) (Table II). Of the elderly patients, 10 had no known previous medical problems, whereas the remaining 35 patients had one or more preexisting medical illnesses. Only 19 of the 90 younger control patients presented with preexisting medical illnesses, with hypertensive ($p < 0.001$) and respiratory ($p = 0.003$) problems being the most significant (Table III).

Pelvic lymphadenectomies were performed in all cases. The number of nodes sampled ranged from 18.5 ± 8.1 in the elderly group to 21.4 ± 8.5 in the younger patients ($p > 0.1$). Paraaortic lymph nodes were sampled in 8 (17.8%) and 25 (27.5%) patients from the elderly and younger groups, respectively ($p = 0.215$).

The mean estimated blood loss during the surgery was 1150 ± 674 ml (range 300 to 3300) in the elderly group and 1513 ± 1596 ml (range 350 to 12,100) in

Table III. Preexisting illnesses in the study populations

	Elderly	*Younger*	*Significance*

Patients with no preexisting illnesses	10	71	
Total No. of illnesses per total No. of patients	57/45*	21/90*	

NS, Not significant.
*Some patients presented with more than one illness.

the younger ($p > 0.1$). The high blood loss value of 12,100 ml represents one patient with trauma and hemorrhage to the hypogastric vein. More than two units of blood was required in 6 (13.6%) of the elderly group versus 29 (32.6%) in the younger group ($p = 0.020$). The duration of the operation was 4 hours 15 minutes in the elderly group and 4 hours 32 minutes ± 52 minutes in the younger groups ($p = 0.100$).

The incidence of surgery-related complications was 5 (11.1%) in the elderly group and 9 (9.9%) in the younger group ($p = 0.825$) (Table IV). These included two intraoperative ureteral injuries necessitating repair (0 elderly, 2 younger), 2 bladder or bowel injuries (1 elderly, 1 younger), and 7 vascular injuries (3 elderly, 4 younger). Three cases required postoperative surgical correction, 1 with bowel obstruction in each group and 1 with ureterovaginal fistula in the younger group.

Early postoperative medical complications occurred more frequently in the elderly group (11.1%) than in the younger group (5.6%) ($p = 0.238$) (Table V). In the elderly group one patient with severe chronic hypoventilation required ventilation assistance and was extubated after bronchodilator treatment on the second postoperative day. In the younger group a lateral pontomedullary infarct developed after a vertebral artery thrombosis in one patient and another patient required ventilation assistance because of fluid overload.

The overall incidence of infectious morbidity was similar in the elderly and the younger groups, 37.8% and 38.5%, respectively ($p = 0.938$) (Table VI). The incidence of surgical site infection and non–surgical site–related infection was 11.1% and 15.5% in the elderly group and 10.0% and 16.5% in the younger group.

Comment

Radiotherapy was the accepted treatment for cervical cancer from the mid-1920s to 1945. Meigs[10] reintroduced the concept of radical surgery for treatment of cervical cancer in 1945. Over the following decades the perioperative morbidity and mortality decreased to very acceptable levels. Recently, because of advances in anesthesia, with improved intraoperative and postoperative monitoring, and the availability of effective broad-spectrum antibiotics, older patients are considered eligible for radical surgery that might have been previously denied.

In this study we have found the mortality and morbidity associated with radical hysterectomy to be similar in elderly and younger patient groups. The major morbidity found in the older group in our study is similar to the overall morbidity reported by others.[11-13] Kinney et al.[14] reported an 11% incidence of complications that required surgical correction in the geriatric population and an 8% incidence of pulmonary embolism. Our report compares very favorably, with only 2.2% of patients requiring reoperation and no cases of pulmonary embolism. The management of stage I cervical carcinoma with radiation therapy in the national practice has a major complication rate of 11%; this rate decreased to 5% in patients >65 years old but increased to 22% in patients <36 years old.[15]

Radical surgery is associated with a high rate of infection-related morbidity because of the extensive dead space created by the dissection, bacterial contamination from the vagina and the often lengthy duration of the operation. The surgical site–related infection rate of

11.1% is similar to the rate (15%) reported by others.[6] The total infection-related morbidity incidence of 38% is within the 23% to 52% range previously reported.[6, 16]

Radical hysterectomy is an operation that traditionally has been reserved for use in the younger population. Our study shows no difference in perioperative complications of radical hysterectomy between younger and older groups. Furthermore, it demonstrates that this is a safe operation that can be performed in elderly patients with American Society of Anesthesiologists physical status I to III.

In summary, with modern perioperative management we are now able to offer this operation to older patients. Age alone should not be considered a contraindication to radical hysterectomy.

Postpartum paravaginal hematoma and lower-extremity infection

Ashwin Chatwani, MD, Todd Shapiro, MD, Amitabh Mitra, MD, Anna LevToaff, MD, and E. Albert Reece, MD

Philadelphia, Pennsylvania

We report a case of infection of the lower extremity after a normal vaginal delivery. The infection originated in an occult obturator internus muscle hematoma, and diagnosis was based on a clinical suspicion and characteristic findings on computerized tomography scan. These findings permitted prompt surgical drainage, debridement, and antibiotic therapy and resulted in a successful outcome. (AM J OBSTET GYNECOL 1992;166:598-600.)

Key words: Paravaginal hematoma, necrotizing fascitis

Infection of the lower extremity is an extremely rare condition in obstetric patients Retropsoal and subgluteal infections and necrotizing fascitis of the lower extremity have all been reported[1, 2] in the obstetric literature. The origin of the infection is presumed to be a paravaginal hematoma. However, the actual presence of a paravaginal hematoma with subsequent abscess formation and spread through the pelvis into the lower extremity has never been previously demonstrated. Additionally, obturator internus muscle hematoma with or without infection has also not been reported previously in the absence of pudendal or paracervical block anesthesia. Hibbard et al.[2] have described the possible route of spread of a paravaginal hematoma abscess. These routes may include a spread through the lesser sciatic foramen towards the hip joint or upward through the broad ligament through the pelvic sidewall. Failure to recognize this rare complication can be associated with severe morbidity or even death.

Case report

F.J., a 27-year-old black woman, gravida 2, para 1, with no significant past medical history was seen in the

Fig. 1. A CT scan of pelvis 1 week postpartum shows hematoma *(H)* of right obturator internus muscle deviating bladder *(B)* left.

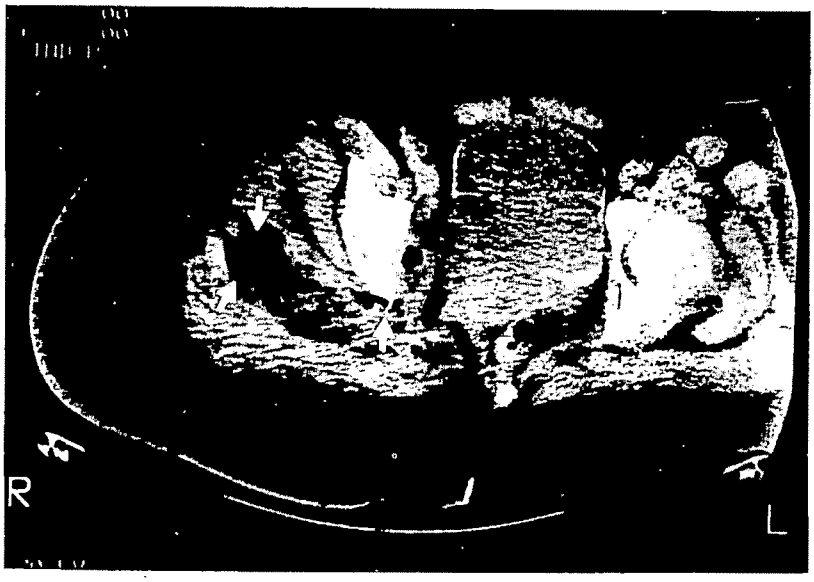

Fig. 2. A CT scan shows gas formation *(arrows)* in obturator internus muscle disseminating into subgluteal region.

labor and delivery suite at 41 weeks' gestation in spontaneous labor after an uneventful prenatal course. She was fully dilated with the vertex at +1 station on admission. She had an uncomplicated normal delivery of a 9-pound female infant after a second stage lasting 1 hour, 5 minutes. No episiotomy was required nor did she receive perineal or pudendal block anesthesia. She had no vaginal or perineal lacerations noted at delivery. The patient was discharged home in satisfactory condition on the third postpartum day.

The patient returned 1 week later complaining of shooting pains in the right buttock radiating down to the back of her thigh. The pelvic examination revealed tenderness along the right ischial spine area with fullness. A computed tomographic (CT) scan of the pelvis was done, which revealed a hematoma of the right obturator internus muscle extending towards the ischial spine (Fig. 1). Admission was recommended for evacuation of the hematoma but was refused by the patient. She returned 1 week later with severe pain in the right leg and inability to walk. Physical examination revealed a very ill patient in excruciating pain. Her temperature was 40.2° C. The right leg was swollen and tender with bullae present around the knee joint and lateral aspect of the thigh. A second CT scan was done, which showed a gas collection extending from the right obturator internus muscle into the subgluteal region (Fig. 2). The scout image from the second CT scan examination demonstrated a large amount of soft tissue gas in the subgluteal region extending into the thigh down to the upper calf (Fig. 3).

The patient was started on ampicillin, gentamicin, and clindamycin and was taken to the operating room where a fasciotomy of the right buttock, thigh, and leg was performed. Necrotic fascia and purulent material were noted to the level of the midcalf. After adequate drainage and debridement, the wound was left open.

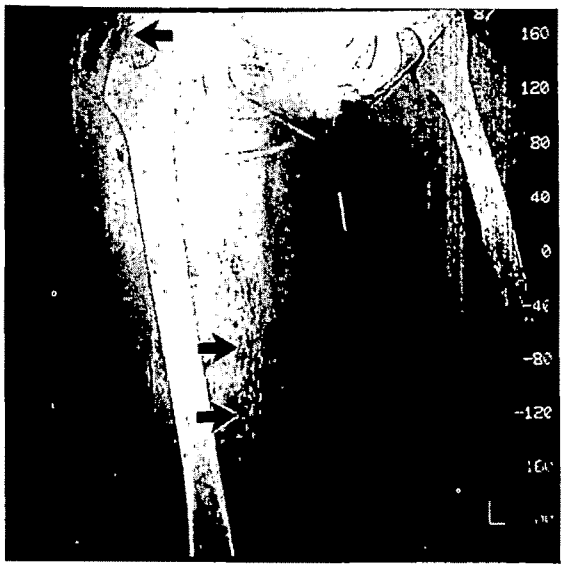

Fig. 3. Scout film for CT scan done 2 weeks postpartum shows gas formation around greater trochanter and disseminated down the leg *(arrows)*.

Cultures of the pus revealed *Escherichia coli* and enterococcus.

After multiple surgical debridements, antibiotic therapy, whirlpool treatment, and extensive physical therapy, the patient was discharged home on the sixty-first hospital day. At the time of discharge, she was fully ambulatory except for some residual discomfort and a slight limp.

Comment

Infection or necrotizing fascitis of the lower extremity after delivery is a rare occurrence. The origin of

this infection is presumed to be a paravaginal hematoma. This complication involving hematoma formation, subsequent infection, and spread to the lower extremity has only been reported with paracervical or pudendal block anesthesia. The present communication describes the first documented case of paravaginal hematoma with subsequent infection and extensions into the lower extremity after an uncomplicated delivery.

The development of a paravaginal hematoma after spontaneous delivery can conceivably occur from rupture or laceration of the pudendal vessel as it courses through the obturator internus fascia. These patients usually remain asymptomatic for a varying period. The initial symptoms are often confused with an orthopedic problem resulting from pregnancy or delivery.

In any paravaginal hematoma, infection can develop by penetrance of vaginal bacteria through small lacerations. Once the hematoma is infected, an abscess may develop. This abscess can extend along the fascia through the lesser sciatic foramen and then along the course of the sciatic nerve down the leg. Alternatively, the infection can spread along the base of the broad ligament to the pelvic sidewall and then through the greater sciatic foramen along the course of the sciatic nerve. An early infection may respond to antibiotics, but, once the destructive abscess has developed and spread has occurred, incision and drainage with debridement of the necrotic tissue along with antibiotic therapy becomes necessary. This case presents a very rare complication of normal vaginal delivery. A postpartum patient with sciatic nerve–type pain should raise the suspicion of a paravaginal hematoma. Prompt investigation with a CT scan and immediate treatment will prevent complication as described herein.

Interrelationship and clinical significance of increased resistance in the uterine arteries in patients with hypertension or preeclampsia or both

Alexander D. Kofinas, MD, Mary Penry, RN, RDMS, Nicolas V. Simon, MD, and Melissa Swain, RN

York, Pennsylvania, and Winston-Salem, North Carolina

OBJECTIVES: This study was designed to evaluate the clinical significance of the Doppler flow velocity waveform analysis of the two uterine arteries on an individual basis and in combination expressed as the mean uterine artery.

STUDY DESIGN: We evaluated uterine artery resistance by means of continuous wave Doppler ultrasonography in 123 pregnant women with chronic hypertension, preeclampsia, or both. The placental location was determined by real-time ultrasonography. Clinical outcomes were compared according to uterine artery abnormalities. The Doppler flow studies were not used in patient management.

RESULTS: In patients with unilateral placentas ($n = 67$) the placental uterine artery was found to be a better predictor of poor pregnancy outcome than the nonplacental artery and the mean of the two arteries. There was a strong degree of correlation between abnormal nonplacental uterine artery and abnormal mean of uterine artery ($r = 0.75$, $p < 0.001$), and there was a moderate degree of correlation between abnormal placental uterine artery and abnormal mean uterine artery ($r = 0.46$, $p < 0.001$). Uterine artery discordance (left − right uterine artery systolic/diastolic ratio) was mostly the result of an abnormal nonplacental uterine artery ($r = 0.74$, $p < 0.0001$) and not the result of an abnormal mean uterine artery ($r = 0.44$, $p < 0.003$); the degree of discordance dic not relate to pregnancy outcome. Unilateral placental location was associated with longer stays in neonatal intensive care units and more perinatal deaths.

CONCLUSION: Because of the differences between the two uterine arteries, we conclude that for proper interpretation of uterine artery flow velocity waveforms, the placental location should be known and each vessel analyzed individually. (Am J Obstet Gynecol 1992;166:601-6.)

Key words: Uterine arteries, hypertension, preeclampsia, Doppler ultrasonography

Intrauterine growth retardation and preeclampsia are both conditions strongly related to proper placental development and function. It has been shown that poor trophoblastic conversion of the spiral arterioles leads to development of intrauterine growth retardation, preeclampsia, or both.[1] Poor trophoblastic conversion results in a decreased uteroplacental vascular capacitance and increased uteroplacental artery resistance. This in turn can lead to decreased uteroplacental bed perfusion, because perfusion is inversely proportional to vascular resistance.

Doppler flow velocity waveform analysis in the uterine arteries performed by continuous wave Doppler ultrasonography is considered a clinically useful method for evaluation of high-risk pregnancies, especially in pregnancies complicated by impaired fetal growth and preeclampsia.[2-7] Some investigators have evaluated only the placental uterine artery and others both uterine arteries collectively. Schulman et al.[8] have shown that both uterine arteries do not respond to pregnancy with the same degree of compliance and that the difference in the resistance (change in systolic/diastolic ratio) between the two uterine arteries correlated well with poor pregnancy outcome. We have shown that placental location can influence uterine artery resistance.[9] Placental laterality is associated with elevated uterine artery resistance and the development of preeclampsia and impaired fetal growth.[10]

The present study was designed to evaluate the relationship between pregnancy outcome and increased resistance in each uterine artery individually and the interrelationship of the two uterine arteries in relation to clinical outcome in patients with hypertension and preeclampsia or both.

Material and methods

A total of 160 patients were enrolled in the study. Seventeen were excluded because of incomplete pregnancy outcome information and 20 because the interval from the last study to delivery was >10 days. The study subjects were recruited from a patient population referred to the antenatal testing unit of Forsyth Memorial Hospital for fetal evaluation because of preeclampsia or chronic hypertension. All patients were examined

after 24 weeks' gestation and no more than 10 days before delivery. Although the majority of the patients underwent more than one evaluation, only the last examination was used in the analysis, because our goal was to examine the relationship of the uterine artery condition to pregnancy outcome as close to delivery as possible. The majority of the patients were inpatients (105) and the rest were outpatients. The physicians involved in the management of the patients were unaware of the Doppler data, and all management decisions were based solely on standard obstetric care practices. The study was approved by the institution's Clinical Research Practices Committee; all patients gave written informed consent.

Diagnosis and classification of the hypertensive disorders were according to criteria established by the American College of Obstetricians and Gynecologists.[11] Patients were considered to have pathologic proteinuria if the total protein level in a 24-hour urine specimen was ≥500 mg or if a random urine specimen obtained by bladder catheterization had a dipstick value of ≥2+. Growth charts appropriate for our population were used to classify the infants as small for gestational age or appropriate for gestational age.[12]

The placental location was determined by real-time ultrasonography.[9] The flow velocity waveforms were obtained with the mother lying comfortably in a slight lateral tilt according to a previously described method.[9] A 4 MHz continuous-wave Doppler device equipped with a real-time spectrum analyzer was used to obtain the uterine artery flow velocity waveforms. The systolic/diastolic ratio was used as an index of resistance in the vasculature distal to the point of insonation. The average of two measurements on each side was classified as right and left uterine artery flow velocity waveform, respectively. When necessary for comparisons, the mean of the right and left uterine arteries was classified as the mean uterine artery flow velocity waveform. In patients with unilateral placenta the uterine artery ipsilateral to the placenta was classified as placental uterine artery and the one contralateral to the placenta as nonplacental uterine artery.

For comparison with previous reports the entire sample ($n = 123$) was analyzed according to the mean uterine artery flow velocity waveform without consideration of the placental location. Whenever we refer to placental and nonplacental uterine artery we consider only the patients with unilateral placentas ($n = 67$), excluding the patients with central placentas.

The flow velocity waveforms were classified as abnormal if there was dicrotic notching in early diastole or if the respective value of the systolic/diastolic ratio exceeded the 95th percentile of our normal values or both. In patients with unilateral placentas the established value is 2.3 for the placental and 3.7 for the nonplacental uterine artery. In patients with central placentas this value is 2.8 and represents the mean of the two uterine arteries.[13] The difference between the right and left uterine artery systolic/diastolic ratio was termed uterine artery discordance.

Statistical analysis was performed by χ^2 test for comparison of frequencies of various pregnancy outcomes. The relationship of placental, nonplacental, and mean uterine arteries was explored with Pearson's correlation coefficient. Comparisons of clinical and Doppler parameters between groups were performed by Student t test for independent samples with unequal variances.

Results

Data from 123 patients were analyzed. Of those 123 patients, 67 had unilateral placentas and 56 had central placentas. There were no differences between the two groups in regard to gravidity, parity, degree of hypertension, degree of proteinuria, gestational age at delivery, and birth weight. However, the uterine artery discordance and the length of stay in the neonatal intensive care unit were different ($p < 0.05$ and $p = 0.05$, respectively). There were seven perinatal deaths in this group of 123 patients with five (72%) occurring in patients with unilateral placentas (Table I). Comparison of patients according to abnormality in the three uterine vessel subgroups (normal vs abnormal mean uterine artery flow velocity waveform, normal vs abnormal placental uterine artery, and normal vs abnormal nonpla-

cental uterine artery revealed no differences in the degree of proteinuria or hypertension.

Tables II through IV demonstrate comparisons of clinical outcomes between normal and abnormal uterine arteries. It is evident that an abnormal placental uterine artery is the best predictor of poor outcome, the abnormal mean uterine artery is second best, and the nonplacental uterine artery was the poorest predictor of clinical outcome. Eighty patients underwent delivery by cesarean section. The majority of them (82%) did so for fetal or maternal indications directly related to the hypertensive disorders and only 18% for obstetric indications not related to the patients' hypertensive disorder. This was the case in all groups of patients. Table V lists the indications for cesarean deliveries. All patients who delivered before 37 completed weeks ($n = 62$) did so because of fetal or maternal indications related to the hypertensive disorder.

The presence of notching in the placental uterine artery regardless of systolic/diastolic value is associated with lower birth weight in neonates of similar gestational age at delivery ($p < 0.02$). In comparing the degree of discordance between right and left uterine arteries in patients with notching and those without, we found that placental uterine artery notching does not affect the degree of discordance between the two uterine arteries in the two groups ($p = 0.7$). However, the presence of notching in the nonplacental uterine artery is associated with a greater discordance between right and left uterine arteries ($p < 0.0001$). Regression analysis of the degree of discordance (change in systolic/diastolic ratio) on the systolic/diastolic ratio of the placental and nonplacental uterine artery and mean uterine artery flow velocity waveform from all patients revealed no correlation between uterine artery discordance and placental uterine artery resistance ($r = -0.09$, $p = 0.5$). To the contrary, there exists a significant correlation between uterine artery discordance and nonplacental uterine artery resistance ($r = 0.74$, $p < 0.0001$). The mean resistance correlates also with the uterine artery discordance but to a lesser degree ($r = 0.44$, $p < 0.003$). Comparisons of clinical characteristics according to the degree of discordance (change in systolic/diastolic = 1, 1.5, and 2) failed to disclose any statistically significant differences, except that the values of the mean uterine artery flow velocity waveform and nonplacental uterine artery were significantly higher in patients with higher discordance. This was true for the entire group and in the group with unilateral placenta. Uterine artery discordance became clinically discriminatory for poor pregnancy outcome only in association with an abnormal mean uterine artery flow velocity waveform.

Seventy-five percent of the patients with abnormal placental uterine artery also have abnormal mean uterine artery flow velocity waveform ($p < 0.004$), and 81% of those with abnormal nonplacental uterine artery also have abnormal mean uterine artery flow velocity waveform ($p < 0.0001$). Thirty percent of the patients with normal placental uterine artery have abnormal mean uterine artery flow velocity waveform ($p < 0.004$), in contrast to only 4% of the patients with normal nonplacental uterine artery who have abnormal mean uterine artery flow velocity waveform ($p < 0.0001$). Abnormal mean uterine artery flow velocity waveform correlates better with abnormal nonplacental uterine artery than with an abnormal placental uterine artery ($r = 0.75$, $p < 0.0001$ and $r = 0.46$, $p < 0.001$, respectively).

Comment

This is the first report to evaluate the clinical significance of abnormal uterine artery resistance for each uterine artery separately in relation to placental location. Previous reports have examined the clinical significance of the subplacental arcuate artery,[6] either one of the two ascending uterine artery branches,[14] or the average of the two uterine arteries.[5] As expected, the results were variable. In part the differences are due to different methods used by various investigators and, to a significant extent, to the differences between the two uterine arteries.

Trudinger et al.[6] limited signal sampling only in the subplacental bed where one can only identify signals from radial and arcuate arteries. Either one of these vessels individually is responsible for only a limited portion of placental bed perfusion and as such it may very well be normal in the presence of significant placental pathology in parts of the placental bed perfused by other arcuate and radial arteries. An abnormal subplacental flow velocity waveform, however, is more likely to be associated with placental pathology because the bulk of blood volume that flows through the subplacental radial and arcuate arteries is directed toward the placental spiral arteries.

Campbell et al.[14] evaluated both ascending uterine arteries with pulsed-wave Doppler and used the most abnormal vessel (highest resistance). From their description and technique it is very likely that some times

they obtained placental and other times nonplacental uterine artery signals. By this method they achieved good sensitivity in predicting problem pregnancies remote from term (18 to 20 weeks' gestation), although the positive predictive value of an abnormal outcome was low. Steel et al.[7] examined one of the two uterine arteries without prior knowledge of the placental location to screen patients at risk for preeclampsia. Abnormal uterine artery resistance at 24 weeks' gestation identified correctly 63% of the patients who subsequently developed preeclampsia. McParland et al.[15] in a subsequent study, treated patients who had abnormal uterine artery resistance with 75 mg aspirin every day in a random, double-blind fashion. The group of patients who were treated presented with a lower incidence of pregnancy-induced hypertension, proteinuric preeclampsia, and intrauterine growth retardation.

Our data suggest that an abnormal placental uterine artery is the best predictor of poor pregnancy outcome, whereas the average of both uterine arteries is the next best and the nonplacental is the least. Several previous reports have clearly demonstrated that the placental uterine artery has a significantly lower resistance than the nonplacental uterine artery.[8, 16, 17] Therefore, when the placental uterine artery is abnormal, there must be a significant degree of placental abnormality. In addition it should be kept in mind that the placental uterine artery reflects pathologic conditions of the majority of the placental bed vasculature. On the other hand, the nonplacental uterine artery is perfusing primarily nonplacental myometrial vessels to the extent that the placenta is unilaterally located.

It seems that in a group of patients with hypertensive disorders and similar risks for poor outcome the presence of a unilateral placenta increases the risk for perinatal death. Seventy-two percent of perinatal deaths occurred in the group with unilateral placentas and only 28% in the group with centrally located placentas. A unilateral placenta was also found to be associated with longer stay in the newborn intensive care unit and increased degree of discordance between the two uterine arteries. Schulman et al.[8] reported significantly increased risk for poor pregnancy outcome with increasing uterine artery discordance. They also found a significant degree of correlation between mean uterine artery flow velocity waveform systolic/diastolic ratio and change in systolic/diastolic ratio (left − right uterine artery systolic/diastolic ratio). Our findings are partially in agreement with regard to poor pregnancy outcome. However, our data demonstrate a moderate degree of correlation between mean uterine artery flow velocity waveform systolic/diastolic ratio and change in

Table IV. Comparison of clinical outcomes in patients with normal versus abnormal nonplacental uterine artery resistance

*Sixty-two of these 66 patients were delivered before 37 completed weeks' gestation.

systolic/diastolic ratio. In contrast, there exists a significant degree of correlation between the nonplacental uterine artery systolic/diastolic ratio and the change in systolic/diastolic ratio. The difference may be due to different methodology. Schulman et al.[8] considered as abnormal a systolic/diastolic ratio of ≥2.8 for both placental and nonplacental uterine arteries. We do not concur with this method, since the 95th percentile of the systolic/diastolic ratio for the placental uterine artery is 2.3 and for the nonplacental uterine artery is 3.7 in our normal population.[12] Our data suggest that the degree of abnormality of the mean uterine artery flow velocity waveform is strongly influenced by the nonplacental uterine artery in patients with unilateral placenta and thus may lose some of its sensitivity because the nonplacental uterine artery may be abnormal in the absence of significant placental pathology.

We conclude that in patients with hypertension, placental uterine artery resistance is a better predictor of poor outcome than the mean and the nonplacental uterine artery. In the same patients the presence of a unilateral placenta is a significant risk factor associated with increased perinatal morbidity and mortality. To extract the best information from uterine artery flow velocity waveform analysis, it is important that the placental location is known and each uterine artery is evaluated individually. For this purpose appropriate reference values that account for placental location should be used. Increasing use of ultrasonographic equipment with Doppler capabilities will render this more feasible and thus improve the level of information about the uteroplacental vasculature in patients with hypertensive disorders.

Direct inhibition of proteases and cervical plasminogen activator by antibiotics

Ariel Milwidsky, MD,[a] Zvezdana Finci-Yeheskel, MSc,[b] and Michael Mayer, DSc[b]
Jerusalem, Israel

OBJECTIVES: Preterm premature rupture of the fetal membranes and premature delivery are sometimes linked to genital tract infection and activation of proteolytic enzymes that degrade the extracellular matrix. The possible beneficial effect of antibiotics in prevention of preterm premature rupture of fetal membranes and retardation of the onset of labor in some patients with clinical or subclinical infection was explained via their antibacterial efficacy. The aim of this study was to determine the effect of antibiotics on proteolytic enzymes as a possible explanation for the ability of antibiotics to retard preterm labor.
STUDY DESIGN: The direct effect of four antibiotics on the proteolytic activities of purified collagenase, elastase, plasmin, trypsin, and chymotrypsin and on streptokinase and human cervical plasminogen activator was measured.
RESULTS: The macrolide antibiotic erythromycin and the beta-lactam antibiotics penicillin G, cloxacillin, and ampicillin exerted, in most of the tested combinations with the different proteases, inhibitory effects on the proteolytic activities.
CONCLUSION: The present finding that antibiotics directly inhibit proteases may offer an explanation for the beneficial response to antibiotic therapy in some cases of idiopathic preterm labor even in absence of pathogenic bacterial infection. (Am J Obstet Gynecol 1992;166:606-12.)

Key words: Preterm premature rupture of the membranes, preterm delivery, plasminogen activator, protease, antibiotics

Preterm premature rupture of the fetal membranes and idiopathic preterm labor are two important factors that provoke fetal prematurity. Although the pathogenesis of preterm premature rupture of membranes is still incompletely understood, some studies suggest that bacterial infections of the genital tract and the associated inflammatory responses are factors that either directly or by predisposition contribute to the initiation of preterm premature rupture of membranes and premature delivery.[1,2] The microorganisms and the neutrophils and macrophages that localize at sites of inflammation produce various hydrolytic enzymes, including proteases, collagenases, elastases, and phospholipases.[1-5] These enzymes can degrade chorionic membrane components and thereby reduce the membranal strength.[5] Bacterial genital infection with *Staph-*

ylococcus aureus, group B streptococci, bacterial vaginosis, and cervical infection with *Chlamydia trachomatis* during pregnancy are known risk factors for preterm premature rupture of membranes.[3, 6, 7] A possible association between infections of the lower and upper genital tract of women, inflammation, and preterm birth is also supported by other studies.[8, 9]

Normal parturition is preceded by structural changes of the cervical matrix leading to softening, dilatation, effacement, and distensibility. These changes result from enhanced hydrolytic cleavage of matrix proteins by proteolytic enzymes such as elastase and collagenase.[10] Elastase is an endopeptidase unique in its ability to cleave the elastic fibrous protein of connective tissue,[11] whereas collagenase has the capacity to cleave native collagen.[12] Increased activity of collagenase occurs concomitantly with cervical dilatation and ripening in human parturition.[10, 13] Both elastase and collagenase are produced from inactive zymogens by proteolytic cleavages that remove a small peptide from the inactive zymogens, thereby creating the active configuration of the enzymes. The endopeptidase plasmin is capable of this activation. Plasmin itself is produced from inactive plasminogen through a specific cleavage by plasminogen activator(s), often present in inflamed tissues.[14] The plasminogen activator(s) and the other proteases may originate from bacteria or leukocytic infiltration that occurs before parturition.[4, 15]

Although entry of vaginal microorganisms into the cervix and lower uterine tissues has been suggested as inducing preterm labor, treatment with antibiotics such as erythromycin was reported to prolong pregnancy in women with cervical effacement and dilatation.[9] Because even the normal cervicovaginal flora produces proteases capable of hydrolyzing the extracellular matrix, a common strategy for prevention of preterm premature rupture of membranes is treatment with antibiotics, even in absence of overt infection. Recently, McGregor et al.[16] reported that bacteria-induced weakening of the fetal membrane can be prevented by levels of antitiotics below those needed to stop bacterial growth, probably reflecting an antibiotic-mediated inhibition of bacterial protease production or release.

Because direct inhibitory effects of certain antibiotics on some proteolytic enzymes were observed earlier,[17-19] it is possible that the proteases that damage the membranes can be directly inhibited by particular antibiotics. Therefore we have determined the effect of several antibiotics on the activities of some purified proteases and on the plasminogen activator activity derived from human cervical tissue.

Material and methods

Materials. Plasminogen was obtained from outdated human plasma by the method described by Deutsch and Mertz[20] with agarose-L-lysine (Bio Yeda, Rehovot). Carbon 14–labeled globin was prepared by formation of carbaminohemoglobin with ^{14}C-labeled potassium cyanate, followed by separation of the globin from heme.[21] Hemoglobin (type III), trypsin from bovine pancreas, chymotrypsin from bovine pancreas, elastase (type IV) from porcine pancreas, and collagenase (type IV) from *Clostridium histolyticum* were purchased from Sigma Chemical Co., St. Louis. Labeled potassium cyanate was obtained from New England Nuclear, Boston; human plasmin from Kabi Diagnostica, Stockholm; streptokinase (Streptase) derived from β-hemolytic streptococci of Lancefield group C from Behringwerke Ag, Marburg; ampicillin (sodium salt) and penicillin G (benzylpenicillin sodium) from Teva, Israel; cloxacillin (sodium) from Bristol Italiana (Sud), Italy; and erythromycin lactobionate (Erythrocin; erythromycin mono (4-O-β-D-galactopyranosyl-D-gluconate) from Abbott Laboratories, North Chicago.

Cervix-conditioned media. Cervical tissue samples were obtained from uteri of women undergoing hysterectomy for various gynecologic indications. The tissue was transferred to the laboratory in ice-cold saline solution and washed with Tris buffer (0.2 mol/L, adjusted to pH 8.0 with hydrochloric acid). Conditioning of the buffer was performed by incubating sections of 1 gm of tissue with 10 ml of the Tris buffer for 2 hours at 37° C. The relative contribution of tissue-type plasminogen activator and non-tissue-type plasminogen activator activities to the total plasminogen activator activity emerging in the conditioned buffer was assessed by inhibition experiments with specific antihuman melanoma tissue-type plasminogen activator antibodies, kindly provided by Dr. Yoav Sharoni, Ben-Gurion University, Beer Sheva.

Globinolytic assay of plasminogen activator activity. Plasminogen activator activity was measured in aliquots of 0.4 ml of the conditioned buffer. Plasminogen, 10 μl of a stock solution of 10 mg/ml, was preincubated for 30 minutes at 37° C with the conditioned buffer. Subsequently, 25 μl of ^{14}C-globin, 336,000 counts/min/mg, 12.5 mg/ml, was added and incubation was continued for 30 minutes. Activity of streptokinase was similarly measured by incubation of purified streptokinase, 10 IU, in 0.4 ml of Tris hydrochloride buffer, 0.2 mol/L, pH 8.0, with globin and plasminogen at the above-stated concentrations for 30 minutes. The reactions were terminated by addition of 250 μl of 50% (wt/wt) ice-cold trichloroacetic acid, and the acid-soluble radioactivity was measured. With this assay the ability of different antibiotics to inhibit plasminogen activator activity of cervix-conditioned medium or purified streptokinase was assayed at increasing levels of antibiotics, ranging from about 0.004 to about 10 mg/ml (10^{-5} to 10^{-2} mol/L).

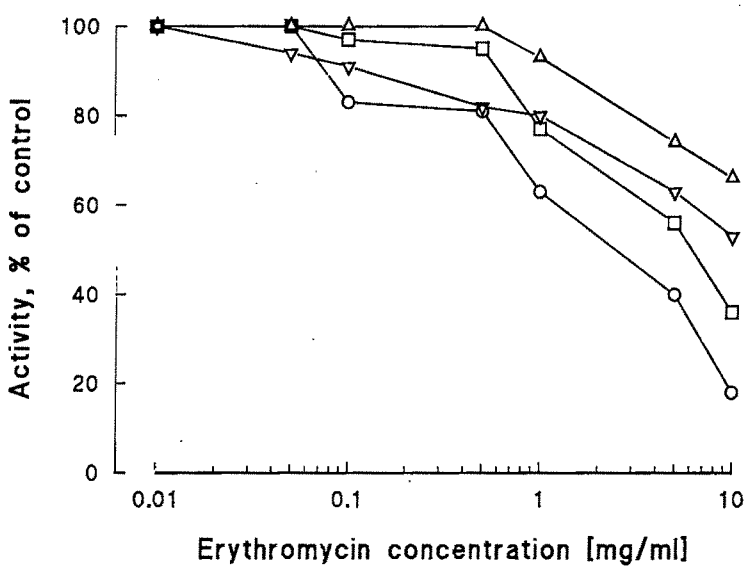

Fig. 1. Effect of increasing concentrations of erythromycin on activity of proteases. Globinolytic activity of 2.5 milli–casein units plasmin (△), 6.7 mU elastase (□), 28.5 U collagenase (○), or 10 IU streptokinase (▽) was determined during 30 minutes of incubation at 37° C. Activity in absence of erythromycin was taken as 100%.

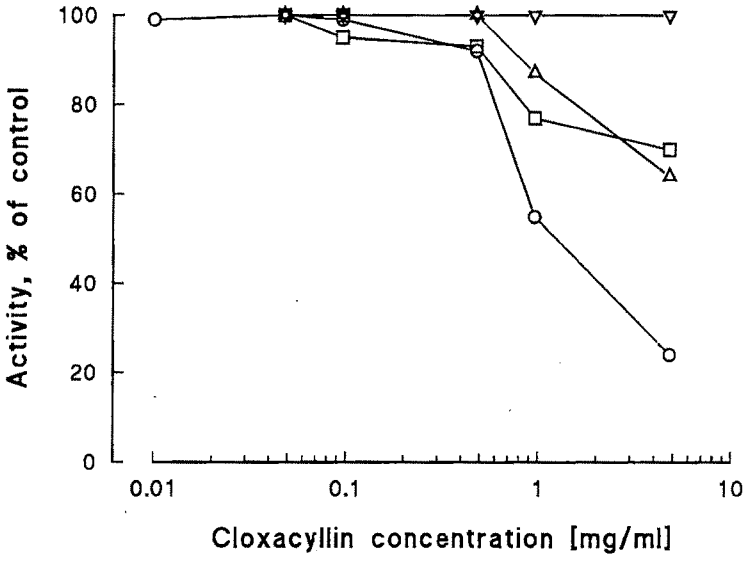

Fig. 2. Effect of increasing concentrations of cloxacillin on activity of proteases. Globinolytic activity of 2.5 milli–casein units plasmin (△), 6.7 mU elastase (□), 28.5 U collagenase (○), or 10 IU of streptokinase (▽) was determined during 30 minutes of incubation at 37° C. Activity in absence of cloxacillin was taken as 100%.

Inhibition of purified proteases by antibiotics. The inhibitory activities of penicillin G, cloxacillin, ampicillin, and erythromycin on the purified enzymes plasmin (2.5 milli–casein units), trypsin (4 IU), chymotrypsin (6.5 mU), collagenase (28.5 U), and elastase (6.7 mU) were determined. Aliquots of 0.4 ml of Tris hydrochloride buffer, 0.2 mol/L, pH 8.0, with or without antibiotic at increasing concentration from 0.005 or 0.1 mg/ml up to 10 mg/ml (i.e., from 10^{-5} up to 10^{-2} mol/L) were incubated with 25 μl of ^{14}C-labeled globin, 16 mg/ml. Incubation was at 37° C for 30 minutes. The reaction was terminated by addition of 250 μl of 50% (wt/wt) ice-cold trichloroacetic acid. The acid-soluble radioactivity was measured.

Kinetic parameters. The kinetic parameters of the different enzymes were established by the globinolytic assay. Collagenase activity was tested by incubating 28.5 U of collagenase in the presence or absence of antibiotic

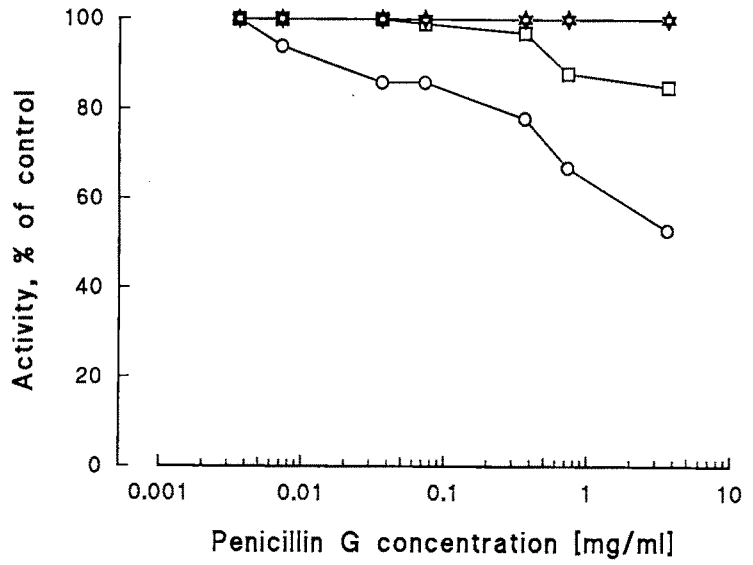

Fig. 3. Effect of increasing concentration of penicillin G on activity of proteases. Globinolytic activity of 2.5 milli–casein units plasmin (△), 6.7 mU elastase (□), 28.5 U collagenase (○), or 10 IU streptokinase (▽) was determined during 30 minutes of incubation at 37° C. Activity in absence of penicillin G was taken as 100%.

in a concentration of 1×10^{-2} mol/L. The enzyme was incubated with different concentrations of the substrate ^{14}C-globin, ranging from 3×10^{-6} to 30×10^{-6} mol/L, in a total volume of 0.4 ml. Cervical plasminogen activator in the conditioned buffer was tested by the globinolytic assay. Conditoned buffer was incubated in the absence or presence of 0.5 mg/ml erythromycin or 0.1 mg/ml cloxacillin (5×10^{-4} mol/L) or 3.6 mg/ml penicillin G (1×10^{-2} mol/L). To determine the type of inhibition, cervical plasminogen activator was incubated with increasing concentration of plasminogen, from 0.75×10^{-7} to 7.6×10^{-7} mol/L.

All experiments were performed in duplicate, and each experiment was run at least three times. Results are taken from representative experiments and are mean values of the duplicate. Variation between reruns of the same experiment never exceeded 7%.

Results

The response of several purified proteolytic enzymes and the response of human cervical plasminogen activator to antibiotic drugs was established in a series of experiments. In these experiments the tested purified enzymes were collagenase, elastase, plasmin, trypsin, and chymotrypsin. The antibiotics used were the macrolide antibiotic erythromycin and the three β-lactams penicillin G, cloxacillin, and ampicillin. All the compounds were tested in a wide concentration range, which included the levels commonly obtained in the plasma during treatment. Fig. 1 shows the effect of increasing concentrations of erythromycin on the activities of the purified proteases. Erythromycin is noted to inhibit the activity of collagenase, elastase, streptokinase, and plasmin. The greatest inhibitory effect occurs on collagenase, followed by a smaller inhibitory effect on elastase and streptokinase, and the lowest inhibition is noted on plasmin activity. The response of the same enzymes to the β-lactam antibiotics cloxacillin and penicillin G is depicted in Figs. 2 and 3, respectively. Again, collagenase and elastase responded with the largest extent of inhibition. Streptokinase activity is refractory to cloxacillin (Fig. 2) and to penicillin (Fig. 3), whereas plasmin activity is inhibited by cloxacillin (Fig. 2) but not by penicillin G (Fig. 3). Other experiments demonstrated that the β-lactam antibiotic ampicillin at concentration >0.37 mg/ml (1×10^{-3} mol/L) inhibits collagenase by 30% and elastase by 20% but has no effect on plasmin or streptokinase. Two additional enzymes, the serine proteases trypsin and chymotrypsin, are also inhibited by erythromycin and cloxacillin; 50% inhibition of trypsin and 65% inhibition of chymotrypsin are obtained with 5 mg/ml (5×10^{-3} mol/L) of erythromycin. A similar concentration of cloxacillin inhibits both enzymes by 20%. In contrast, penicillin G and ampicillin do not inhibit trypsin and cause only a slight inhibition (10%) of chymotrypsin activity, and only at the high concentration of 3.6 mg/ml (1×10^{-2} mol/L).

The results described indicated that among the four tested proteases collagenase is the most sensitive to inhibition by antibiotics. The kinetic parameters of collagenase in absence and in presence of the antibiotics are summarized in Table I. Erythromycin, penicillin G, and cloxacillin are seen to be noncompetitive inhibitors.

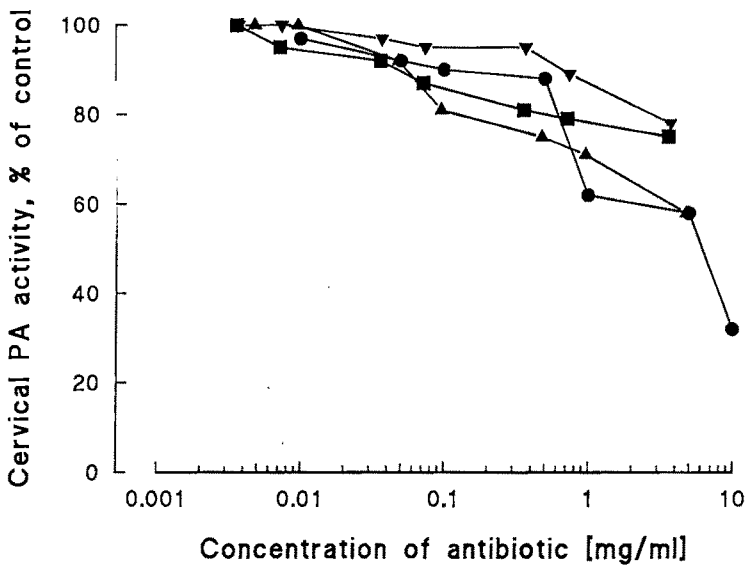

Fig. 4. Effect of different antibiotics on globinolytic activity of human cervical plasminogen activator *(PA)*. Increasing amounts of ampicillin (▼), penicillin G (■), cloxacillin (▲), or erythromycin (●) were incubated in 0.4 ml aliquots of medium conditioned with human cervix. The plasminogen activator activity of cervix-conditioned buffer was assayed by addition of 10 μl plasminogen for 30 minutes at 37° C. Subsequently, 25 μl of ^{14}C-globin was added and incubation was continued for additional 30 minutes.

Table I. Kinetic parameters for collagenase activity in presence of different antibiotics

Antibiotic	*Maximal velocity of reaction* ($pmol \cdot min^{-1} \cdot U^{-1}$)	*Michaelis-Menten constant* ($\mu mol \cdot L^{-1}$)
None	4.0	16.8
Erythromycin (10.0 mg/ml)	2.4	18.6
Penicillin G (3.6 mg/ml)	3.1	20.7
Cloxacillin (4.8 mg/ml)	2.3	20.7
Ampicillin (3.7 mg/ml)	2.7	11.4

Collagenase, 28.5 U, was incubated at 37° C for 30 minutes in absence or presence of 1×10^{-2} mol/L of different antibiotics. Total volume was 0.4 ml. Collagenase activity was assayed with ^{14}C-globin as substrate in a range of concentrations between 3×10^{-6} and 3×10^{-5} mol/L. Number in parentheses are concentrations of the tested antibiotics.

The v (initial reaction velocity) versus v/[S] plots for these three compounds intersect to the left of the v axis, suggesting that they do not affect the binding of the substrate to collagenase. In contrast, ampicillin is an uncompetitive inhibitor of collagenase, and increasing concentrations of ampicillin yield a set of parallel curves in reciprocal v versus [S] plots (not shown).

To test the effect of antibiotics on cervical plasminogen activator activity, the enzyme was tested in buffer conditioned with freshly obtained human cervical tissue. The plasminogen activator activity recovered from the cervix-conditioned buffer is composed of 80% tissue-type and 20% non-tissue-type plasminogen activator activity. This conclusion is based on measurements of the degree of inhibition of cervical plasminogen activator activity by antihuman tissue-type plasminogen activator antibodies. The effect of four antibiotics on the total plasminogen activator activity in the buffer conditioned with human cervix is shown in Fig. 4. The activity is inhibited by all tested compounds. The largest inhibitory effect is noted with erythromycin, whereas the lowest degree of inhibition is exerted by ampicillin.

Kinetic analysis of the effect of antibiotics on human cervical plasminogen activator activity showed that penicillin G, cloxacillin, and erythromycin do not affect the maximal velocity of the reaction but increase the Michaelis-Menten constant, suggesting a mechanism of competitive inhibition. These kinetic assays were performed by the dual-stage, plasminogen-dependent test, with the use of levels of erythromycin and cloxacillin that are below those that inhibit human plasmin, e.g., 0.5 and 0.1 mg/ml (5×10^{-4} mol/L), respectively. Penicillin G, which does not inhibit human plasmin, was tested at 3.6 mg/ml (1×10^{-2} mol/L). Concordantly, the increased Michaelis-Menten constant reflects an effect on plasminogen activation and not on plasmin activity.

Comment

These findings show that the activities of proteases that are considered to play a role in preterm premature

rupture of membranes and cervical ripening[1, 3, 10, 13, 15] are directly inhibited by several antibiotics. Therefore the ability of antibiotics to offer a certain protective effect against preterm premature rupture of membranes and their capacity to protract premature delivery may be partially ascribed to their ability to suppress proteases that mediate these processes. Thus, regardless of the source of the proteases, either from normal bacterial flora of the genital tract or from pathogenic bacterial infections or even from inflammatory granulocytes or monocytes-macrophages that invade the tissue, the different antibiotics can partially suppress hydrolytic activity. It has already been suggested that antibiotics extend the time from treatment to delivery in patients with idiopathic preterm labor and cervical dilatation.[9] McGregor et al.[16] noted that erythromycin at a level that is subinhibitory to bacterial growth effectively prevents bacteria-induced reduction of fetal membrane strength. This effect suggested an antibiotic-mediated inhibition of the production or secretion of bacterial proteases.[16] Likewise, the administration of ampicillin or erythromycin, even in absence of clinical signs of infection, results in delayed delivery.[22] The currently described inhibition of proteases by antibiotics may offer an additional explanation for the ability of certain antibiotics to support the integrity of fetal membranes.

We have noted earlier that urokinase activity is inhibited by penicillin G in a competitive manner, whereas ampicillin had no effect.[17] It was suggested that the hydrophobic side chain rather than the β-lactam moiety of the antibiotic is responsible for this inhibition. Tissue-type plasminogen activator demonstrated a similar inhibition by several penicillins.[18]

These findings imply that the mechanism of inhibition of collagenase by ampicillin differs from the mode of action of the other tested antibiotics. The difference is indicated by the changes produced by the various antibiotics in the kinetic parameters of collagenase, as summarized in Table I. The values are derived from sets of experiments in which the initial reaction velocity, v, is determined at increasing substrate concentrations. The maximal velocity of the reaction is obtained when the substrate concentration is so high that essentially all the enzyme is saturated. The Michaelis-Menten constant is numerically equal to the substrate concentration at which the initial reaction velocity is half-maximal. As seen in Table I, ampicillin decreases these two factors of collagenase to the same extent, suggesting its binding to the collagenase-substrate complex rather than to the free enzyme.[23] The other three antibiotics exhibit noncompetitive inhibition, suggesting their ability to form a collagenase-substrate-antibiotic complex that is catalytically inactive.[23]

Elastase and collagenase are produced and secreted from cells in latent forms that require activation within the extracellular matrix.[12, 24] This activation can be mediated by various proteases, including trypsin and plasmin. However, only plasmin activates latent collagenase without destruction and appears to be involved in the in vivo activation of latent collagenase.[12] Plasmin itself is the product of activation of the inactive proenzyme plasminogen by plasminogen activators or by traces of preformed plasmin. Finally, the plasminogen activators themselves are often produced as inactive proenzymes that depend on activation for activity.

Since the existence of collagenase and elastase in latent forms represents a mechanism to control their extracellular activity, the ability to control their conversion to active enzymes by inhibition of proteolytic activities in the cervix may be of clinical relevance. Thus direct suppression of the protease-dependent activation of matrix-degrading enzymes by antibiotics may reduce the incidence and delay the onset of cervical dilatation, preterm premature rupture of membranes, and preterm labor.

The importance of bacterial infection in the etiology of preterm birth has been recently disputed on the basis that patients undergoing preterm delivery exhibit normal vagina flora and by the failure of adjunctive antibiotic therapy to prevent preterm labor.[25] This recent observation should now be reexamined in view of the direct effect of antibiotics on the activity of proteases that are most likely involved in the etiology of preterm premature rupture of membranes and preterm labor.

The effect of fetal sepsis on umbilical cord blood gases

Bruce A. Meyer, MD, Jan E. Dickinson, MD, Charles Chambers, MD, and Valerie M. Parisi, MD, MPH

Houston, Texas

The relationship between fetal sepsis and acid-base status is unknown. We hypothesized that in utero sepsis would result in fetal metabolic acidemia. In a retrospective study during a 38-month period, the acid-base status at birth of neonates with in utero sepsis, documented by positive blood cultures, was reviewed. Compared with term neonates, preterm neonates had a 22-fold increase in the risk of bacteremia at birth. In spite of this increased risk of sepsis, there was no significant alteration in arterial pH in preterm septic neonates when compared with preterm controls. Fetal sepsis at term was accompanied by a statistically significant reduction in arterial pH (7.21 ± 0.07) compared with controls (7.26 ± 0.06, $p < 0.05$). When controlled for other variables, the decrease in arterial pH at term was correlated with an increased duration of labor (7.3 ± 0.7 in controls vs 10.8 ± 0.9 hours in neonates with sepsis, $p < 0.05$). The classic predictors of chorioamnionitis were found to be poor prognostic indicators of fetal bacteremia. Fetal sepsis at term is associated with a deterioration in the fetal acid-base status and a prolongation of labor. (Am J Obstet Gynecol 1992;166:612-7.)

Controversy exists regarding fetal infection in utero and its effect on acid-base status. In the adult, septicemia has been associated with progressive metabolic acidemia.[1] This has lead to the inference that in utero sepsis may have a similar deleterious effect on fetal acid-base balance. Fetal in utero infection has been implicated as a cause of birth asphyxia.[2,3] In contrast, in the

presence of premature rupture of the membranes, chorioamnionitis does not alter umbilical cord pH.[4] Additionally, in the presence of chorioamnionitis, immediate delivery affords no maternal[5] or neonatal[6] advantage when appropriate antibiotic therapy is provided. Thus the exact relationship between fetal sepsis and umbilical cord blood gas parameters is unknown. The purpose of this study was to establish the effect of infection acquired in utero on fetal acid-base status at birth. We hypothesized that in utero sepsis would result in a fetal metabolic acidemia.

Material and methods

The neonatal records of all infants with positive blood cultures within the first 24 hours of life who were admitted to the nursery at Hermann Hospital (Houston) from January 1986 through March 1989 were reviewed. Neonates with positive blood cultures within 24 hours of birth were considered to have acquired their infection in utero. Because of concerns with contamination, infants with cultures that revealed nonaureus staphylococcus were included only if two blood cultures were positive. When mothers with premature rupture of the membranes were treated with antepartum antibiotics, their neonates were excluded from analysis. Umbilical cord arterial and venous blood gas parameters were used to determine the fetal acid-base status at birth. Sixty-six neonates met these criteria. In five newborns with sepsis blood gases could not be determined from the umbilical cord, and these values were unavailable for analysis. Only those neonates with an arterial specimen were included in the study. The maternal obstetric records of the 61 neonates who met the study criteria were then analyzed. Controls were obtained by manually reviewing the maternal and neonatal medical record of the next consecutive delivery; they were specifically matched for maternal age and parity, socioeconomic status, gestational age, birth weight, and mode of delivery. Health care delivery service was used as a marker for socioeconomic status. Patients cared for by the University of Texas Women's Clinic, by a private health maintenance organization, or by private physicians were eligible for inclusion in the study. The following maternal criteria were evaluated: chronic medical conditions, complications of pregnancy, duration of ruptured membranes, number of vaginal examinations, duration of labor, requirement for oxytocin augmentation, fetal heart rate (FHR) abnormalities, presence of meconium-stained amniotic fluid, mode of delivery, type of analgesia, febrile morbidity, and antibiotic administration. All nulliparous women were managed by a modified active management of labor protocol, as previously described.[7] Oxytocin was administered to multiparous women at the discretion of the attending physician. Continuous electronic FHR monitoring was performed in all patients. FHR abnormalities were defined according to the criteria of Freeman and Garite.[8] The diagnosis of chorioamnionitis was based on the presence of maternal temperature $\geq 38°$ C and one or more of the following: maternal tachycardia, fetal tachycardia, uterine tenderness, or malodorous amniotic fluid. Umbilical cord arterial and venous blood gases were obtained at all births at Hermann Hospital during the study period. Immediately after delivery, a segment of umbilical cord was clamped, divided, and handed to the delivery room nurse. Preheparinized 3 ml syringes (Marquest Medical Products, Englewood, Col.) were used to obtain a consistent dose and preparation of heparin. All samples were obtained in the delivery room and placed on ice. Analysis was performed within 15 minutes of delivery by a laboratory technician on a blood gas analyzer (IL-1312, Allied Co., Lexington, Mass.) located in the satellite laboratory adjacent to the labor and delivery area. Statistical analysis was performed by paired t test, multivariate Hotelling t^2 test, χ^2, and Fisher's exact test as appropriate. This was accomplished with statistical software packages (SPSS-PC, SPSS Inc., Chicago, and Abstat, Anderson-Bell, Parker, Col.). A p value of <0.05 was chosen to represent statistical significance.

Results

There were 16,345 deliveries at Hermann Hospital during the study period. Sixty-one neonates (29 term and 32 preterm deliveries) met the inclusion criteria and were matched with controls. Statistical analysis confirmed no significant differences between control and septic groups for the matched variables of age, parity, gestational age, and birth weight, respectively (Table I). There were no significant differences in racial distribution between the control and septic groups (46% black, 36% white, 18% Hispanic vs 48%, 34%, 18%, respectively). Distribution of healthcare services was 48% private health maintenance organization, 34% University of Texas clinic, and 18% private patients for each group. The cesarean section rate in this selected population was 23%. Betamethasone for fetal pulmonary maturation was given to 24% ($n = 8$) of preterm septic neonates and 20% ($n = 7$) of preterm controls ($p > 0.20$). The preterm birth rate at our institution during the study time period was 5.0%. Thus 4.3% of preterm and 0.2% of term deliveries met the criteria for sepsis acquired in utero. The incidence of in utero–acquired infection was significantly different between these groups ($p < 0.05$, odds ratio 22.4, 95% confidence limits 15.9 and 31.7). Analysis of the arterial umbilical cord gases revealed a significant decrease in pH in the septic neonates when compared with controls ($p < 0.05$). In addition, the bicarbonate and base excess were significantly lower in the septic neonates. There

was no alteration in arterial respiratory gas values when septic and control groups were compared. These data are summarized in Table II. Venous umbilical cord blood gases analysis also showed a significant decrease in pH in the septic cases when compared with controls ($p < 0.05$). Bicarbonate and base excess were also significantly lower in the septic neonates. Venous respiratory parameters were not altered. These data are summarized in Table III. The data were divided into preterm (<37 completed weeks of gestation) and term subsets to evaluate the effect of gestational age on cord blood gases in this population. There were no differences in umbilical arterial or venous blood gas parameters when preterm septic neonates were compared with preterm controls (Tables II and III). However, within the term subset there was a significant decrease in the arterial and venous pH ($p < 0.05$). In both arterial and venous specimens, the bicarbonate and base excess were significantly lower in the septic neonates. There were no alterations in arterial P_{O_2} or P_{CO_2} when term septic neonates were compared with controls. The respiratory component of venous gases were altered, as venous P_{O_2} was significantly lower while P_{CO_2} was significantly higher in the septic group (Tables II and III). FHR tracings were evaluated by the attending physician. The occurrence of any abnormality on FHR tracing was noted in 36% ($n = 22$) of septic and 33% ($n = 20$) of control neonates ($p > 0.20$). Two thirds of these abnormalities consisted of fetal tachycardia (>160 and <180 beats/min) or mild variable decelerations in both groups. When divided into term and preterm subsets, there were no differences in the incidence of significant FHR abnormalities (poor variability, severe variable or late decelerations) when compared with controls (10% vs 8%; $p > 0.20$). There was a significant increase in the duration of labor in the overall septic versus control group ($p < 0.05$). When preterm septic and control groups were compared, there was no significant difference in the length of labor ($p > 0.20$). However, there was a significant prolongation of labor when the term septic subset was compared with term controls ($p < 0.05$). The observed difference in the duration of labor in the overall group was accounted for by the 45% increase in the length of labor among term septic neonates. We have previously defined fetal acidemia as an arterial cord pH <2 SD from the mean of our population.[7] Using this criterion, the incidence of acidemia was significantly greater in the septic neonates compared with controls (9/61 vs 1/61, $p < 0.05$). Notably, eight of the nine acidemic neonates with cord arterial pH values of <7.14 had a duration of labor >12 hours. The control neonate with an acidemic pH had a cesarean section for presumed fetal distress after 3 hours of labor. One of the nine neonates with sepsis had a significant FHR abnormality, and elimination of this case does not change the significance ($p < 0.05$). The small numbers of patients precludes analysis of the term and preterm subsets. There was a significant in-

*$p < 0.05$, versus control.

crease in febrile morbidity among the mothers of septic neonates. Intrapartum fever (>38° C) occurred more frequently in mothers of septic newborns when compared with mothers of controls (26% vs 2%, respectively; $p < 0.05$). This febrile morbidity was evident in both the term and preterm septic subgroups when compared with controls (24% vs 0% and 28% vs 3%, respectively). The clinical diagnosis of chorioamnionitis was made significantly more often in the overall term and in the preterm septic groups when compared with controls ($p < 0.05$). In addition, there was a significant increase in the incidence of postpartum endomyometritis when mothers of septic newborns were compared with controls ($p < 0.05$) (Table IV). The duration of ruptured membranes was significantly longer in the overall septic group when compared with controls ($p < 0.05$). The preterm septic subset accounted for this difference (Table IV). In the overall group, there was a significant increase in the incidence of prolonged rupture of membranes (>24 hours) when septic neonates were compared with controls ($p < 0.05$). This difference was also attributable to the preterm subset (Table IV). There was a significant increase in the incidence of meconium-stained amniotic fluid in the overall septic group when compared with controls ($p < 0.05$). There was no statistically significant difference in the requirement for oxytocin augmentation in any of the populations studied (overall, 28% (17) vs 39% (24); term, 38% (11) vs 48% (14); preterm, 19% (6) vs 31% (10); $p > 0.20$). Similarly, there were no significant differences in regional analgesia usage (overall, 31% (20) vs 39% (24); term, 59% (17) vs 69% (20); preterm, 9% (3) vs 13% (4); $p > 0.20$). There were also no significant differences in the assignment of a 5-minute Apgar score <7 when neonates with sepsis were compared with controls in the overall, term, or preterm groups (12% vs 23%, 3% vs 13%, and 20% vs 33%, respectively; $p > 0.20$). The bacterial pathogens isolated included a variety of microorganisms, two thirds of which were group B streptococcus, *Escherichia coli* and staphylococcus species. Analysis of the isolates demonstrated a significant increase in the incidence of group B streptococcal infection in term septic when compared with preterm septic neonates (19/29 vs 11/32, respectively, $p < 0.05$). There were no differences in arterial or venous umbilical cord blood gas parameters between neonates with group B streptococcal infection compared with septic neonates with

other pathogens. One neonate in each subset had more than one pathogen identified. There were eight neonatal deaths among the septic neonates (three term, five preterm), whereas there was one neonatal death in the control group, in the preterm subgroup.

Comment

Delivery of the fetus when intrauterine infection is diagnosed or strongly suspected is currently accepted obstetric practice.[9, 10] However, no maternal[5] or neonatal[6] benefit to immediate delivery has been demonstrated with intrapartum antibiotic administration. Little is known about the relationship between in utero infection and fetal acid-base status. In this study, we have demonstrated that fetal sepsis is associated with a decrease in the umbilical arterial pH, accompanied by metabolic alterations in the arterial blood gases. These metabolic changes are evidenced by decreases in pH, bicarbonate, and base excess without alterations in arterial P_{O_2}, or P_{CO_2}. Assessment of the influence of gestational age on the arterial blood gas values indicates that the differences are accounted for by the term septic subgroup. Term septic neonates display a significant decrease in arterial pH, bicarbonate, and base excess when compared with matched nonseptic controls. Similar changes are observed in the venous umbilical cord blood gases. In the term septic subgroup, both metabolic and respiratory alterations are observed, as venous P_{O_2} is significantly decreased while P_{CO_2} was significantly elevated. This may be due to an impairment in placental function due to local infection or to a reduction in maternal perfusion in the presence of sepsis. The latter speculation is unlikely to be of significance, as only four of these women had blood culture–proved sepsis and only 30% had a clinical diagnosis of chorioamnionitis. These factors may compound the metabolic changes associated with sepsis in fetal arterial blood gases.

Curiously, cord blood gases from the preterm septic newborns are not significantly different from their nonseptic controls, in spite of the greater incidence of chorioamnionitis and prolonged rupture of the membranes in the mothers of this group. We postulate that the lack of alteration in acid-base status is likely due to the significantly shorter duration of labor in this subpopulation. This suggests that fetal sepsis with a short duration of labor does not cause significant changes in fetal acid-base status. We speculate that fetal sepsis plus prolonged labor may cause accelerated deterioration in acid-base status, as demonstrated in the term septic subgroup.

To evaluate the etiology of the observed metabolic changes in the term septic neonates, several obstetric factors were assessed. There were no significant differences found in the duration of ruptured membranes, incidence of prolonged ruptured membranes, oxytocin usage for augmentation of labor, fetal meconium passage, or regional analgesia use in the term septic versus nonseptic groups. The only obstetric factor in which term septic neonates differed from controls was in the duration of labor. A significant prolongation in the mean duration of labor was present when term septic neonates were compared with their nonseptic term controls. This significant prolongation of labor held true even when term septic neonates were compared with the preterm septic and preterm control groups. In addition, the incidence of labor duration >12 hours was significantly higher only in the term septic subset. Eight of the nine neonates with an arterial pH of <7.14 had labor >12 hours. This lends further credence to the detrimental effect of prolonged labor on acid-base balance in the presence of fetal sepsis. It is unclear from this data whether the in utero sepsis per se had a direct effect on the fetus (i.e., through lactic or other fixed acids) or whether this was a physiologic response to the increased duration of labor in the face of an already stressed septic fetus. Deterioration in fetal acid-base status with increasing duration of labor has been demonstrated previously by other authors.[11] However, as there were no differences in the length of labor when preterm septic neonates were compared with preterm controls, it is unlikely that sepsis directly causes an increase in the length of labor. Thus the observed metabolic alterations in arterial blood gas parameters appears to be attributable to the combination of fetal sepsis and increased duration of labor.

To ensure that our study population was representative of true fetal infection, we chose to assess only neonates with bacteremia documented by positive blood culture within the first 24 hours of life. These selection criteria may not include all infected neonates but do provide a study population with clearly defined sepsis. The intrapartum maternal administration of antibiotics may have rendered neonatal cultures negative in a bacteremic newborn; the exclusion of these patients from our study may have confounded the interpretation of our results. The spectrum of infectious microorganisms in this study was comparable to those of previous investigators.[12, 13] Group B streptococcal infection did not disproportionately contribute to the observed differences in arterial blood gas values. The classic maternal markers of chorioamnionitis were poor prognostic indicators of fetal sepsis. Clinical chorioamnionitis was diagnosed in only 27% of mothers of septic neonates. Features often associated with maternal antenatal sepsis, such as prolonged rupture of the membranes, duration of labor >12 hours, and postpartum endomyometritis, were present significantly more often in mothers of septic neonates than in those of nonseptic

controls. Because the majority of mothers of bacteremic neonates do not have clinical findings of chorioamnionitis, the clinical diagnosis of fetal intrauterine sepsis is extremely difficult. Additionally, the occurrence of fetal sepsis may be independent of clinical maternal infection.

Previous studies[4, 6] assessing the effect of in utero sepsis on umbilical cord blood gas parameters have focused on the diagnosis of chorioamnionitis and its impact on the fetus. Laboratory investigation revealed that the majority of these neonates were not septic. Therefore the umbilical cord blood gas values do not necessarily reflect the effect of sepsis on fetal acid-base balance. The incidence of early neonatal bacterial sepsis in our study was four in 1000 live births, in keeping with previous reports of 1 to 5 in 1000 live births.[12]

Early identification of the fetus with in utero sepsis is critical for instituting appropriate antibiotic therapy. However, the diagnosis of fetal sepsis is difficult, with recognizable chorioamnionitis being present in only the minority of cases. A high index of suspicion remains the major diagnostic criterion, with prolonged rupture of membranes and increased duration of labor being major risk factors. The 22-fold increase in the risk of bacteremia at birth in preterm versus term neonates may be due to a number of factors. These include ascending infection as the cause of preterm premature rupture of the membranes and the preterm delivery and the significant increase in the duration of membrane rupture in preterm neonates.

In our study fetal sepsis at term was accompanied by a statistically significant reduction in arterial and venous pH. The metabolic alterations in the arterial blood gases are likely due to lactic acidemia secondary to the infection. Although of statistical significance, these differences remain well within the previously reported normal range at our institution[14] and may not be clinically significant. Our data suggest that acidemia at birth is a poor predictor of fetal sepsis, as >85% of septic neonates had a normal cord pH. Additionally, these data confirm the findings of Ramin et al.[15] that neither fetal nor maternal sepsis is an indication for cesarean section.

The clinical significance of these findings lies in the increased incidence of fetal acidemia in septic neonates and in the association between increased duration of labor and fetal sepsis. From our study it is unclear whether fetal sepsis can contribute to a prolongation of labor or whether prolonged labor leads to fetal sepsis. However, our findings lend support to the concepts of active management of labor, which have been demonstrated to reduce the duration of labor.[16] In our institution, application of these principles has decreased the duration of labor without altering fetal acid-base status.[7]

There are four major conclusions that can be drawn from our study: (1) Fetal sepsis with short duration of labor does not cause significant changes in acid-base status; (2) fetal sepsis alone does not cause an increase in the duration of labor; (3) there is, however, an association between the duration of labor, fetal sepsis and fetal acidemia at term; (4) preterm neonates have a significantly increased risk of fetal sepsis when compared with term neonates. Further study of the potential clinical effects of fetal sepsis is indicated.

Eradication of *Ureaplasma urealyticum* from the amniotic fluid with transplacental antibiotic treatment

Roberto Romero, MD, Zion Hagay, MD, Jose Nores, MD, Waldo Sepulveda, MD, and Moshe Mazor, MD

New Haven, Connecticut, and Detroit, Michigan

Ureaplasma urealyticum was isolated from the amniotic fluid of a patient with preterm premature rupture of membranes at 24 weeks. A second amniocentesis performed 48 hours later indicated an increase in the number of neutrophils in the amniotic fluid. Treatment with erythromycin, ampicillin, gentamicin, and clindamycin was instituted for a period of 6 days. Amniotic fluid analysis from a third amniocentesis performed 24 hours after discontinuation of antibiotic treatment revealed only a few white blood cells and was negative for microorganisms. The pregnancy continued for 22 days after admission, at which time spontaneous labor began. The neonate survived with no sequelae and had negative blood cultures. Antibiotic treatment was associated with eradication of *Ureaplasma urealyticum* from the amniotic cavity, pregnancy prolongation, and neonatal survival. (AM J OBSTET GYNECOL 1992;166:618-20.)

Key words: *Ureaplasma urealyticum*, chorioamnionitis, antibiotic treatment, prematurity, premature rupture of membranes

A growing body of evidence suggests an association between subclinical intraamniotic infection and preterm delivery. *Ureaplasma urealyticum* is one of the most frequently isolated microorganisms from the amniotic fluid of women in preterm labor with intact membranes and from women with preterm premature rupture of membranes.[1] This microorganism has been implicated in the etiology of both maternal and fetal-neonatal infections.

The current standard management of a pregnancy complicated by microbial colonization of the amniotic cavity, as detected by transabdominal amniocentesis, has been induction of labor to prevent the maternal and fetal consequences of infection. In women with preterm gestations (i.e., <26 weeks), this approach often results in significant perinatal morbidity and mortality because of extreme prematurity. There has recently been interest in alternative management schemes to this problem, including antibiotic administration, with the aim of eradicating microbial colonization and preventing the development of infection.[2]

The purpose of this article is to report the successful eradication of *U. urealyticum* colonization of the amniotic cavity by maternal treatment with erythromycin.

Case report

A 26-year-old woman, gravida 4, para 0, spontaneous abortions 2, elective abortions 1, was admitted to Yale–New Haven Hospital because of preterm premature rupture of membranes at 24 weeks' gestation. A sterile speculum examination was positive for an amniotic fluid pool in the vagina, ferning, and a Nitrazine test. The maternal temperature was 99.2° F, and the white blood cell count was 11,400/mm³. The differential count was as follows: segmented cells, 68%; bands, 13%; lymphocytes, 14%; and monocytes, 5%. A sonogram showed a single fetus in vertex presentation and a decreased amniotic fluid volume. Fetal biometry was consistent with 24 weeks of gestation, and the estimated fetal weight was 760 gm. Amniotic fluid, retrieved by transabdominal amniocentesis, showed the presence of white blood cells (+1), but no bacteria were found by Gram stain examination. Amniotic fluid was cultured for aerobic and anaerobic bacteria and for *Mycoplasma* sp. with the Mycotrim system (Mycotrim-GU, Berkeley, Calif.). Forty-eight hours later, the amniotic fluid culture was reported to be growing *U. urealyticum*. There was no clinical evidence of chorioamnionitis, and the white blood cell count was 9600/mm³. The differential count showed segment cells, 51%; bands, 32%; lymphocytes, 12%; and monocytes, 5%. An amniocentesis was repeated to confirm the diagnosis and for evaluation of amniotic fluid. The number of white blood cells observed increased dramatically (+4), but still no microorganisms were visualized by Gram stain examination.

The patient was started on a regimen of erythromycin (1 gm, every 6 hours, intravenously), clindamycin (900 mg, every 8 hours, intravenously), gentamicin (80 mg, every 8 hours, intravenously), and ampicillin (2 gm, every 4 hours, intravenously).

Erythromycin was chosen to cover *U. urealyticum,* and the other antibiotics were added to broaden the spectrum of coverage for other microorganisms that might not have been identified because of their fastidious nature. Four days after the second amniocentesis, the laboratory confirmed that the culture of amniotic fluid grew *U. urealyticum.* Antibiotic treatment was continued for 6 days. Twenty-four hours after discontinuation of antibiotic treatment, a third amniocentesis was performed. There were only a few white blood cells, and the Gram stain examination revealed no microorganisms. Amniotic fluid culture was negative for bacteria and *Mycoplasma* sp.

The patient remained asymptomatic for two additional weeks. At that time she complained of vaginal bleeding and went into labor. A repeat amniocentesis was declined. A 1090 gm male neonate was born spontaneously at 27 weeks 3 days of gestation with Apgar scores of 1 at 1 minute and 5 at 5 minutes. The cord pH was 7.28. The neonate required intubation and mechanical ventilation. All neonatal cultures were negative. Four days after birth, the newborn was extubated. Two weeks later, the infant was transferred to another nursery. Follow-up 1 year later shows that the infant has experienced normal neurologic and intellectual development. Histopathologic examination of the placenta demonstrated severe inflammation, suggesting that chorioamnionitis had occurred. There was no evidence of puerperal endometritis.

Comment

This case represents the first report of eradication of *U. urealyticum* colonization of the amniotic fluid with maternal antibiotic therapy. This management approach was associated with continuation of pregnancy for 22 days after the amniocentesis and the birth of a more mature preterm infant.

U. urealyticum is present in the genital tract in as many as 80% of women with normal pregnancy. The mere presence of this microorganism in the genital tract is not a risk factor for preterm delivery. However, *U. urealyticum* is frequently isolated from the amniotic fluid of women in preterm labor, with or without intact membranes.[1]

Once microbial invasion of the amniotic cavity has been established by analysis of fluid retrieved by transabdominal amniocentesis, the standard management approach has been expeditious delivery. This approach has evolved to prevent maternal and fetal infection. The implicit premise is that the natural history of microbial colonization of amniotic fluid is to progress toward infection. Data obtained from patients with preterm premature rupture of membranes who underwent serial amniocenteses indicate that the inoculum size increases with time in patients with a positive amniotic fluid culture, and this is eventually associated with the onset of labor.[1] More data are required to establish whether the natural history of *U. urealyticum* colonization of the amniotic fluid is similar to that described for bacteria.

In this patient's case we were faced with three alternative management schemes: (1) to adopt the traditional approach and induce labor, (2) to observe the patient and await the spontaneous onset of parturition or the development of clinical chorioamnionitis, or (3) to attempt to eradicate colonization of the amniotic cavity. Because of the extreme prematurity of the fetus, we believed that induction of labor would have significant risk for the fetus. Although expectant management could be defended as a reasonable approach, our experience with microbial colonization in the setting of premature rupture of membranes has been that spontaneous onset of labor, and often infection, develops in a relatively short period of time.[1] Since our group had previously successfully eradicated amniotic fluid colonization and prolonged pregnancy in a case of preterm premature rupture of membranes with a mixed bacterial infection, this approach had considerable appeal.[2]

Our choice of antimicrobial therapy deserves comment. In vitro studies of the antimicrobial sensitivity of *U. urealyticum* have shown that up to 90% of strains are sensitive to erythromycin. However, in vivo studies indicate that this antibiotic is ineffective in eradicating *U. urealyticum* from the lower genital tract. This discrepancy between in vitro and in vivo data has been attributed to the effect of the vaginal pH, since erythromycin is a less effective antimicrobial agent at low pH. Because erythromycin crosses the placenta and reaches the amniotic cavity and the amniotic fluid had a neutral pH, we believed that this antimicrobial agent would be the best choice. We chose to add the other antibiotics to cover fastidious microorganisms that may not have been recovered before initiation of this therapy.

Although the amniotic cavity was sterile after discontinuation of antibiotic therapy, it is unknown if microbial colonization recurred before delivery because the patient declined an amniocentesis at the time of onset of preterm labor. In this case neonatal cultures were negative, indicating that if colonization of the amniotic cavity had recurred, it had not caused a systemic neonatal infection. Histopathologic examination of the placenta suggested acute chorioamnionitis; therefore it is tempting to postulate that the failure of host-defense mechanisms that led to the original colonization of the amniotic cavity allowed recolonization once antibiotic treatment was discontinued. A small separation of the placenta may have been responsible for the vaginal bleeding and may also have contributed to the initiation of preterm labor.[3]

This case demonstrates that antibiotic administration to the mother is a reasonable option for the management of colonization of the amniotic cavity in cases of

extremely preterm gestations. In our case prolongation of pregnancy was accomplished without mishap to the mother or the fetus.

Vaginal Po_2 in healthy women and in women infected with *Trichomonas vaginalis*: Potential implications for metronidazole therapy

Abdel L. Rashad, MD, PhD,[a] William L. Toffler, MD,[b] Nina Wolf, RN,[b] Kent Thornburg, PhD,[c] E. Paul Kirk, MD,[d] Gene Ellis, AAS, RRT,[e] and W.E. Whitehead, BS[a]

Portland, Oregon

We measured the Po_2, pH, and temperature in the vaginal canals of nine patients with symptomatic *Trichomonas* vaginitis and those of 10 healthy women. The patients included eight women with primary infections caused by metronidazole-susceptible strains and one refractory case that resulted from infection with a metronidazole-resistant *Trichomonas vaginalis*. The median vaginal Po_2, pH, and temperature in the patient group were 1 mm Hg, 6, and 37.3° C respectively; these medians were 1 mm Hg, ≤4.5, and 37.2° C in the healthy group. These data show that vaginal environment is anaerobic or microaerophilic (it has reduced oxygen tension). Because the activity of metronidazole is reduced under aerobiosis, the vaginal environment should enhance the biologic activity of the drug. (AM J OBSTET GYNECOL 1992;166: 620-4.)

Key words: Vaginal Po_2, metronidazole, trichomoniasis

The activity of antimicrobial agents is influenced by local factors that reside at the infected site.[1, 2, 3] This is relevant to the vaginal canal, in which the in vitro activity of metronidazole against *Trichomonas vaginalis* is shown to be enhanced when tests are performed under anaerobic conditions.[4, 5] Increased activity of metronidazole under anaerobiosis is most noticeable when metronidazole-resistant isolates are examined.[6, 7] This report defines the physiologic parameters of the vaginal environment with particular emphasis on Po_2 in two groups of women: patients with vaginal infection caused by *T. vaginalis* and healthy women not infected with *T. vaginalis*. Vaginal Po_2 was measured with a transcutaneous O_2 monitor that uses a miniature Clark electrode (Novametrix Medical Systems, Inc., Wallingford, Conn.)

Material and methods

Subjects studied included nine patients suffering from symptomatic *Trichomonas* vaginitis documented by positive wet mount and culture and 10 healthy women without vaginitis in whom wet mount and culture were negative for *T. vaginalis*. Research protocol was ap-

proved by the institution's Committee on Human Research, and each participant signed a consent form before the investigation was conducted. Wet mounts of vaginal secretions were examined for *T. vaginalis*, clue cells, and yeast or hyphae. In addition, fungal cultures for *Candida* were performed. Cultures for *Trichomonas* were performed with modified Diamond's medium (which incorporates vancomycin, 20 μg/ml; gentamicin, 20 μg/ml, and amphotericin B, 10 μg/ml instead of the penicillin G and streptomycin used in the original formula) and Feinberg-Whittington medium. The vaginal pH was measured by exposing a nitrazine paper strip (E.R. Squibb and Sons, Inc., Princeton, NJ) to the vaginal secretions. The scale on the paper strip ranged from pH 4.5 to pH 7.5. The vaginal Po_2 was measured with a transcutaneous O_2 monitor 811 (Novametrix Medical Systems, Inc., Wallingford, CT), which uses a miniature Clark electrode. The instrument was calibrated according to the manufacturer specifications. The high Po_2 was set at the calculated partial pressure of atmospheric oxygen (corrected for water vapor pressure) and zero Po_2 was set at zero during the application of the manufacturer's zero Po_2 solution. The electrode was further checked against solutions gassed with different mixtures of oxygen and was measured with a Radiometer BMS3 Mk2 (Radiometer, Copenhagen, Denmark) blood gas analyzer that is calibrated with commercial gas mixtures. In test solutions, the electrode was always within 2 mm Hg of the blood gas electrode, even at high Po_2 (about 150 torr). Thereafter, the probe was inserted into the vagina without the introduction of ambient air and was left in place until a constant reading was obtained for at least 2 minutes. Vaginal Po_2 was measured first; this was followed by the collection of specimens for wet mount examination, culture, and pH measurement. None of the women in the healthy or *Trichomonas* groups were menstruating when Po_2 was measured. Metronidazole in vitro susceptibility tests were performed by means of microdilution and macrodilution broth methods on *T. vaginalis* isolates from eight patients. The procedure used was a modification of that described by Meingassner and Thurner.[4] Susceptibility tests were performed at 37° C under aerobic and anaerobic conditions of incubation. Minimal inhibitory concentration (MIC) was recorded as the lowest drug concentration that resulted in complete inhibition of motility of trichomonad cells. Each variable was summarized by calculating the median and range for each group. The two groups (patients with trichomoniasis and healthy controls) were compared on each variable with the Mann-Whitney test.

Results

Table I summarizes the data from nine trichomoniasis patients and 10 healthy women. Two of the patients (one of whom represented a primary infection and the second, a refractory infection) had had hysterectomies. Eight of the nine patients had primary infections. Seven were cured by the standard metronidazole therapeutic regimen (either single-dose or multidose). The eighth patient could not be treated because of severe allergy to metronidazole. Isolates from seven of these eight patients were available for in vitro susceptibility testing. The median (range) aerobic and anaerobic MICs were 2.5 μg/ml (1.25 to 10 μg/ml) and 1.25 μg/ml (0.6 to 2.5 μg/ml), respectively. The refractory patient was a 34-year-old woman who had had persistent infection for the previous 15 months in spite of attempts on two occasions to achieve a cure with the multidose oral metronidazole regimen. Factors

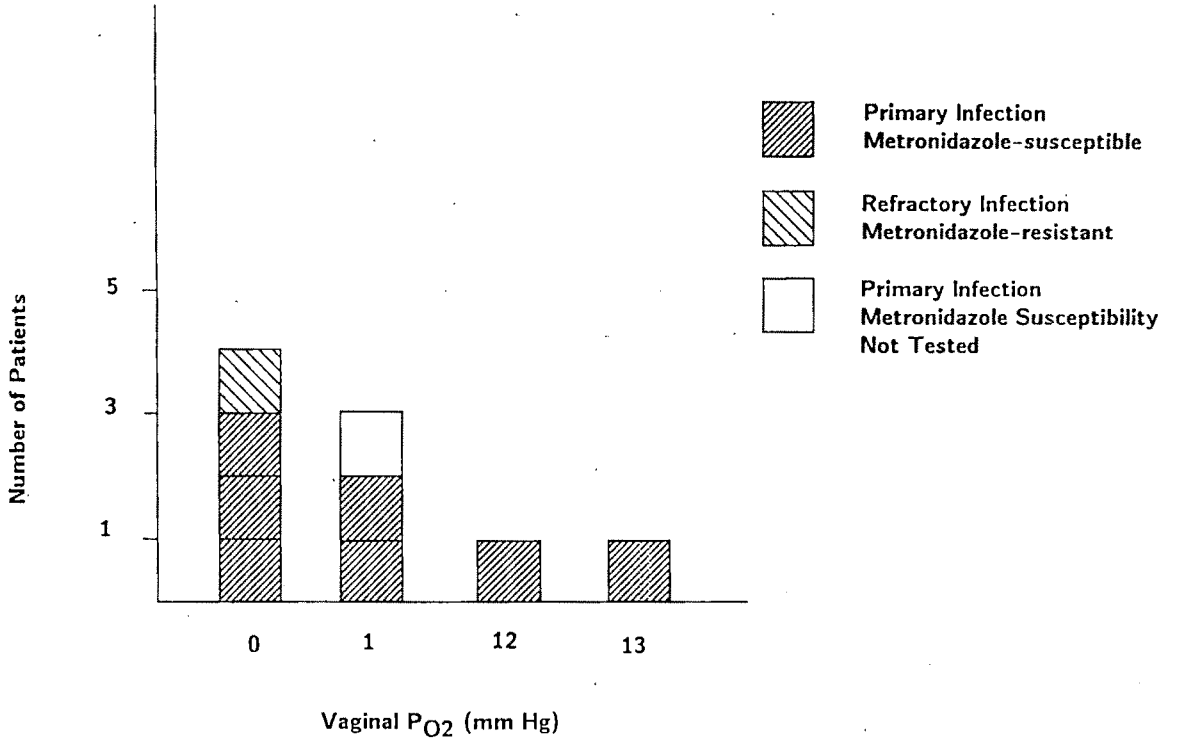

Fig. 1. Vaginal P_{O_2} in nine patients infected with *Trichomonas vaginalis*.

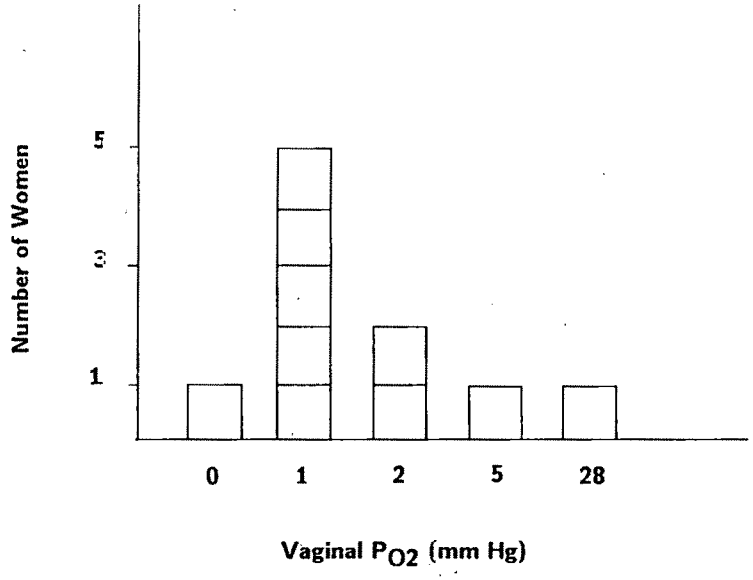

Fig. 2. Vaginal P_{O_2} in 10 healthy women.

such as reinfection and poor compliance (ruled out by measuring metronidazole blood levels) were excluded as contributions to therapeutic failure. The median aerobic and anaerobic MICs for the isolate recovered from this patient were ≥160 μg/ml and 2.5 μg/ml, respectively. The vaginal P_{O_2} was measured on two different occasions in this refractory patient, and the results were 0 mm Hg and 1 mm Hg. The median number of days between P_{O_2} measurement and onset of last menstruation was 16 days in the patient group (range 8 to 28 days) and 12 in the healthy control group (range 7 to 30 days). There was no difference in the median vaginal P_{O_2} values in the patient or control groups ($p = 0.23$). There also was no difference in the vaginal

temperatures of women in both groups ($p = 0.21$) or in the number of days between Po_2 measurement and the onset of last menstruation ($p = 0.22$). There was a tendency for the vaginal pH values to be higher in the patients compared with those of the controls; the respective median values were 6.0 and ≤4.5 ($p = 0.07$). Figures 1 and 2 illustrate the distribution of vaginal Po_2 measurements in the patient group and the healthy women groups.

Comment

Local factors residing at the infected site are known to affect the activity of antimicrobial agents.[1, 2, 3] Conditions in vitro, such as medium composition and atmospheric condition of incubation, influence the MIC and minimal lethal concentrations of antimicrobial agents.[8, 9] Activity of metronidazole against *T. vaginalis* is enhanced by anaerobiosis. Aerobic MICs tend to be higher than do anaerobic MICs. This is most noticeable in metronidazole-resistant strains recovered from refractory cases.[10, 11, 12] In 1979 Meingassner and Thurner[4] were first to isolate a metronidazole-resistant *T. vaginalis* strain from a patient afflicted with recurrent symptomatic trichomoniasis. The aerobic and anaerobic minimal lethal concentrations were 100 and 0.4 μg/ml, respectively. Before that time, refractory cases of trichomoniasis that failed to respond to metronidazole therapy were usually attributed to factors such as reinfection from male consorts, poor compliance, or inadequate drug levels that were due to poor absorption and/or inactivation or competition for drug by vaginal microbial flora.

Currently, no standardized test is available for determining in vitro susceptibility of *T. vaginalis* to metronidazole. Nevertheless, the test described by Meingassner and Thurner[4] or one of its modifications[5] has been successfully used to identify metronidazole resistance. To discriminate between metronidazole-susceptible and metronidazole-resistant strains, the test must be performed under aerobic conditions of incubation. Our study shows that the vaginal environment is anaerobic or microaerophilic (it has reduced oxygen tension). The vaginal Po_2 was ≤2 mm Hg in all but four of the 19 women (two healthy women and two patients) evaluated. Studies by Holmes et al.[13] demonstrated a reduced vaginal redox potential in bacterial vaginosis. The redox system was in a more reduced state in women with bacterial vaginosis than in controls. Successful treatment with metronidazole resulted in a decrease in vaginal pH that was accompanied by an increase in reduced vaginal redox potential. Wagner and Ottesen,[14] in their study of vaginal physiology during menstruation measured the Po_2 in a group of young healthy women. Mean Po_2 in the menstrual fluid on day 2 (in four women studied) and on day 4 (in three women) after the onset of menstruation were 52 and 46 mm Hg, respectively. These investigators also measured the vaginal Po_2 and demonstrated a wide range of values from 0 to 77 mm Hg. They attributed the variation in Po_2 to differences in the release of menstrual blood from the cervical canal into the vagina. It is also possible that the high Po_2 values observed in some of the women in that study may have resulted from obtaining the measurements after the menstrual fluid had been collected and a speculum had been inserted to obtain samples for culture. None of the women who participated in our study was menstruating when measurements were obtained. Furthermore, special care was taken to avoid introduction of air into the vagina before Po_2 was measured. Samples for cultures were collected after Po_2 was measured.

The factors responsible for maintaining a low Po_2 in the vaginal canal are not known, but this may be due to activity of the vaginal microbial flora. The microbicidal effect of metronidazole on *Trichomonas* results from reductive activation of the drug, which yields cytotoxic short-lived reduced intermediates.[15] An anaerobic environment or an environment of reduced oxygen tension within the vaginal canal should enhance the biologic activity of metronidazole. A low Po_2 in the vagina should raise the question of whether in vitro testing in aerobic conditions reflects the degree of in vivo resistance. Lossick et al.[6] have recently recognized that MIC and minimal lethal concentration measurements derived from tests performed in air tend to overestimate the degree of in vivo resistance. These authors and others cured more than 85% of refractory trichomoniasis cases that resulted from infection with metronidazole-resistant strains by administering metronidazole in doses much larger than those of the standard regimen; this suggests that resistance is relative.[6, 16, 17]

We thank Dr. Gary Sexton for help with statistical analysis.

Immunoreactive circulating endothelin-1 in normal and hypertensive pregnancies

Eyal Schiff, MD,[a] Gilad Ben-Baruch, MD,[a] Edna Peleg, PhD,[b] Talma Rosenthal, MD,[b] Menachem Alcalay, MD,[a] Michal Devir, MD,[a] and Shlomo Mashiach, MD[a]

Tel-Hashomer, Israel

OBJECTIVE: The purpose of this study was to measure the circulatory levels of endothelin-1 in the serum of pregnant women with hypertension.
STUDY DESIGN: Endothelin-1 levels were measured by means of radioimmunoassay in the serum of 26 pregnant women with hypertension (14 with pregnancy-induced preeclamptic toxemia, 12 with chronic hypertension) and in the serum of 17 control pregnant women and 18 control nonpregnant women. The mean levels in the different groups were subject to statistical analysis with the analysis of variance.
RESULTS: The mean level among the women with preeclampsia (29.9 ± 13.2 fmol/ml) was significantly higher than those of the chronically hypertensive women (16.1 ± 7.3 fmol/ml, $p = 0.002$) and of the control pregnant women (19.7 ± 9.2 fmol/ml, $p = 0.011$). The mean level of the control nonpregnant women (26.9 ± 9.3) was significantly higher than that of the control pregnant women ($p = 0.029$). Among the patients with preeclampsia there was no correlation between endothelin-1 levels and the mean arterial blood pressure. Six to 10 weeks after delivery the mean levels of 15 studied patients (7 with preeclampsia, 8 with chronic hypertension) were similar to the levels of the nonpregnant control women.
CONCLUSION: We conclude that increased endothelin-1 production may play a role in the pathogenesis of preeclampsia. (AM J OBSTET GYNECOL 1992;166:624-8.)

Key words: Endothelin-1, preeclampsia

Endothelin-1, a 21-amino-acid peptide recently discovered by Yanagisawa et al.,[1] is the most potent natural pressor substance known. The messenger ribonucleic acid for endothelin-1 has so far been detected only in endothelial cells. Certain substances, including thrombin and epinephrine, reportedly cause the in vitro release of endothelin-1 from endothelial tissue.[2] Al-

6/1/32399

though endothelin-1 is rapidly eliminated from the bloodstream,[3,4] its intravenous injection in animals produces diffuse vasoconstriction and relatively prolonged arterial hypertension.[5,6] High levels of endothelin-1 have been detected in the sera of patients with essential hypertension[7] and acute renal disorders,[8,9] whereas endothelin-1 activity was recently shown to interact with vasoactive prostaglandins.[10-12] Therefore one might expect endothelin-1 to play a role in the pathophysiologic composition of preeclamptic toxemia, a disorder characterized by hypertension in pregnancy, impaired renal function, systemic vasospasm, and altered production of vasoactive prostaglandin in platelets and endothelial tissue. The purpose of this study was to compare the activity of endothelin-1 in hypertensive pregnant women in general with those in normal pregnant and nonpregnant women. Because it is assumed that chronic hypertension in pregnancy and preeclampsia are distinct entities, we compared particularly the activity of endothelin-1 among these two groups of pregnant women.

Patients and methods

Patients. The study group consisted of 26 women, between 20 and 39 years old, in the third trimester of pregnancy, who were admitted to our department over a 3-month period because of pregnancy-induced hypertension, i.e., systolic blood pressure >140 mm Hg or diastolic pressure >95 mm Hg at least twice within 6 hours. The disappearance (phase V) Korotkoff sound was used to define diastolic blood pressure. Twelve of the patients had a history of hypertension before the twentieth week of the current pregnancy and were accordingly designated as chronically hypertensive. None of these patients had proteinuria of >0.5 gm/24 hours on admission. The other 14, all of them nulliparous with no history of hypertension before the third trimester, were conisdered to have preeclampsia. Nine of these patients had proteinuria of >0.5 gm/24 hours on admission. We also classified the women, whether chronically hypertensive or preeclamptic, according to the severity of the hypertensive disorder; in those with systolic blood pressure <160 mm Hg, diastolic blood pressure <110 mm Hg, and proteinuria of ≤+1, the disorder was considered to be mild to moderate, whereas in those with higher systolic or diastolic blood pressure or proteinuria of ≥+2 it was classified as severe. Within 24 hours of admission, brachial venous blood (10 ml) was withdrawn from each patient, none of whom was yet in spontaneous or induced active labor.

Two control groups consisted of 35 women aged between 20 and 39 years who were randomly chosen over the same period. The first consisted of 17 pregnant women in the third trimester of pregnancy, all of whom had normal blood pressure and no previous history of hypertension. The second consisted of 18 healthy, nonpregnant women with no history of essential hypertension or previous hypertension in pregnancy. Venous blood samples were withdrawn from all the women in the control groups.

The women in the study group and in the first and second control groups were similar with respect to both mean age (27.4 ± 5.5, 28.8 ± 3.8, and 27.9 ± 4.1 years, respectively) and parity (1.9 ± 0.7, 1.5 ± 0.6 and 1.9 ± 0.9, respectively). Six to 10 weeks (median 57 days) after delivery we reexamined 15 of the patients in the study group. After determining that the preeclamptic women were no longer hypertensive and had no proteinuria and that the chronically hypertensive women had blood pressure values similar to those before being pregnant, we remeasured the venous blood endothelin-1 levels.

Methods. Blood was collected in tubes containing 7.5 mmol/L ethylenediaminetetraacetic acid and aprotinin (500,000 IU/ml), centrifuged immediately at 4° C, and stored at −20° C until assayed. After acidification and passage through Amprep 500 mg C_2 columns (Amersham Int., England), endothelin-1 levels in the serum were determined by means of the iodine 125–labeled endothelin-1,2 assay system (Amersham), with a sensitivity of 1.03 fmol per tube, an intrassay coefficient of variation of 4.1%, and an interassay coefficient of variation of 13%. Cross-reactivity with endothelin-3 was 0.0024%.

The results and data regarding patients characteristics are reported as the mean ± SD. Statistical comparisons between the groups were carried out by means of the analysis of variance test. Comparisons between patients' endothelin-1 levels before and after delivery were carried out by means of the adjusted paired Student t test. Differences were considered significant if the p value was <0.05. The correlation between mean arterial pressure (Mean arterial pressure = ⅔ Diastolic pressure + ⅓ Systolic pressure) and endothelin-1 levels was determined according to univariate linear regression and the Pearson coefficient of correlation.

Results

The serum endothelin-1 levels of the women in the different groups are shown in Fig. 1. The mean level in the preeclamptic study subgroup (29.9 ± 13.2 fmol/ml) was significantly higher than that of both the chronically hypertensive study subgroup (16.1 ± 7.3 fmol/ml, $p = 0.002$) and the normal pregnant control group (19.7 ± 9.2 fmol/ml, $p = 0.011$) and similar to the mean level in the nonpregnant control group (26.9 ± 9.3 fmol/ml). The mean level in the nonhypertensive pregnant control group was significantly lower than that of the nonpregnant control group ($p = 0.029$) and similar to that of the chronically hy-

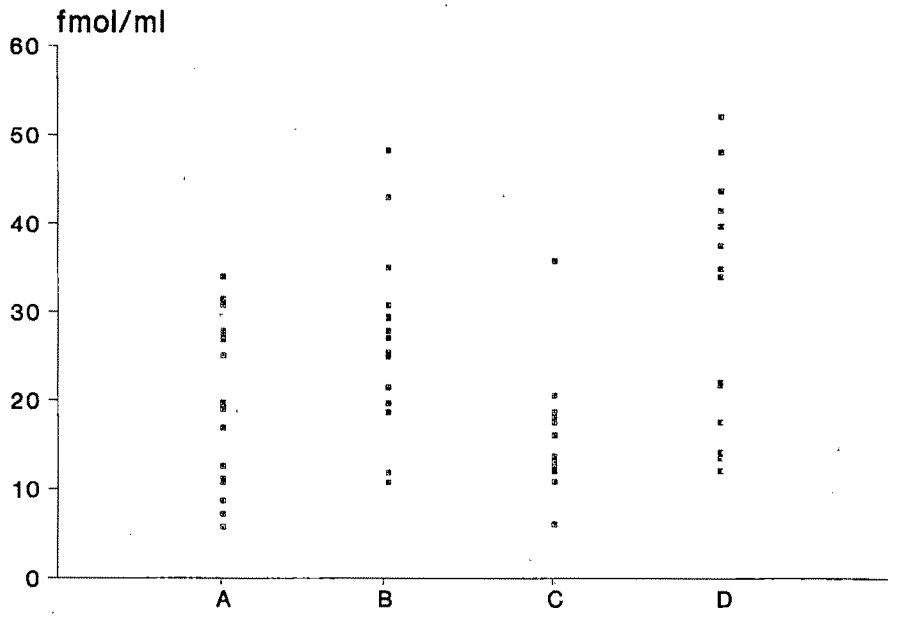

Fig. 1. Serum endothelin-1 levels of women in different groups. **A,** Normal pregnant controls; **B,** nonpregnant controls; **C,** chronic hypertensive; **D,** preeclamptic.

pertensive study subgroup. Within the two study subgroups we found no significant differences between mean serum endothelin-1 levels of patients with severe hypertensive disorder compared with those with a mild to moderate one; five patients with severe chronic hypertension (average blood pressure >160 mm Hg systolic or 110 mm Hg diastolic) had a mean endothelin-1 level similar to that of the other seven mild to moderate chronically hypertensive patients (14.9 ± 11.8 and 14.9 ± 4.7 fmol/ml, respectively). Eight severely preeclamptic patients who had average blood pressure >160 mm Hg systolic or 110 mm Hg diastolic ($n = 6$) or proteinuria of ≥+2 ($n = 7$) had a slightly but not significantly higher mean endothelin-1 level compared with that of the other patients with mild to moderate preeclampsia (32.3 ± 13.3 and 28.9 ± 15.2 fmol/ml, respectively).

The mean arterial pressure (when blood samples for endothelin-1 measurements were withdrawn) was 117.7 ± 11.1 mm Hg for the chronically hypertensive patients and 116.2 ± 11.9 mm Hg for the preeclamptic patients. No correlation between circulatory endothelin-1 levels and mean arterial blood pressure was found for all the study group ($n = 26$, $r^2 = 0.09$) and when the correlation test was restricted to the preclamptic patients only ($n = 14$, $r^2 = 0.19$).

Fig. 2 compares the serum endothelin-1 levels of 15 study group patients measured 6 to 10 weeks after delivery, when the patients were normotensive, with their levels during the acute hypertensive phase before delivery. The mean endothelin-1 level of the eight chronically hypertensive women of the study group (study subgroup 1) had significantly increased from 13.2 ± 3.7 to 21.6 ± 8.7 fmol/ml ($p = 0.05$), whereas that of the seven preeclamptic women of the study group (study subgroup 2) had slightly but not significantly increased from 21.2 ± 4.6 to 27.2 ± 5.8 fmol/ml ($p = 0.07$). The new mean levels after delivery were now similar to that of the nonpregnant control patients (26.9 + 9.3 fmol/ml).

Comment

Preeclamptic toxemia of pregnancy is a major cause of obstetric and perinatal morbidity.[13] Its pathophysiologic composition, however, is not well understood. Some authors have suggested that the primary abnormality of this disorder is an aberrant platelet metabolism,[14] with overproduction of vasoactive prostaglandins[15] and consequent endothelial damage and increased peripheral vascular resistance. The resulting symptoms are increased systemic blood pressure, alterations in renal function, and activated coagulation state.

Because the recently discovered endothelium-derived peptide endothelin-1 is a highly potent vasoconstrictor and because elevated levels have already been implicated as a possible factor in essential hypertension,[7] acute renal failure,[8, 9] and platelet hyperreactivity,[16] we were interested in investigating the possible role of endothelin-1 in the etiology of preeclampsia. Two recent reports by Kamoi et al.[17] and Taylor et al.[18] demonstrated relatively high levels of endothelin-1 in a small group of women with pregnancy-induced hypertension, as determined by means of sandwich-type

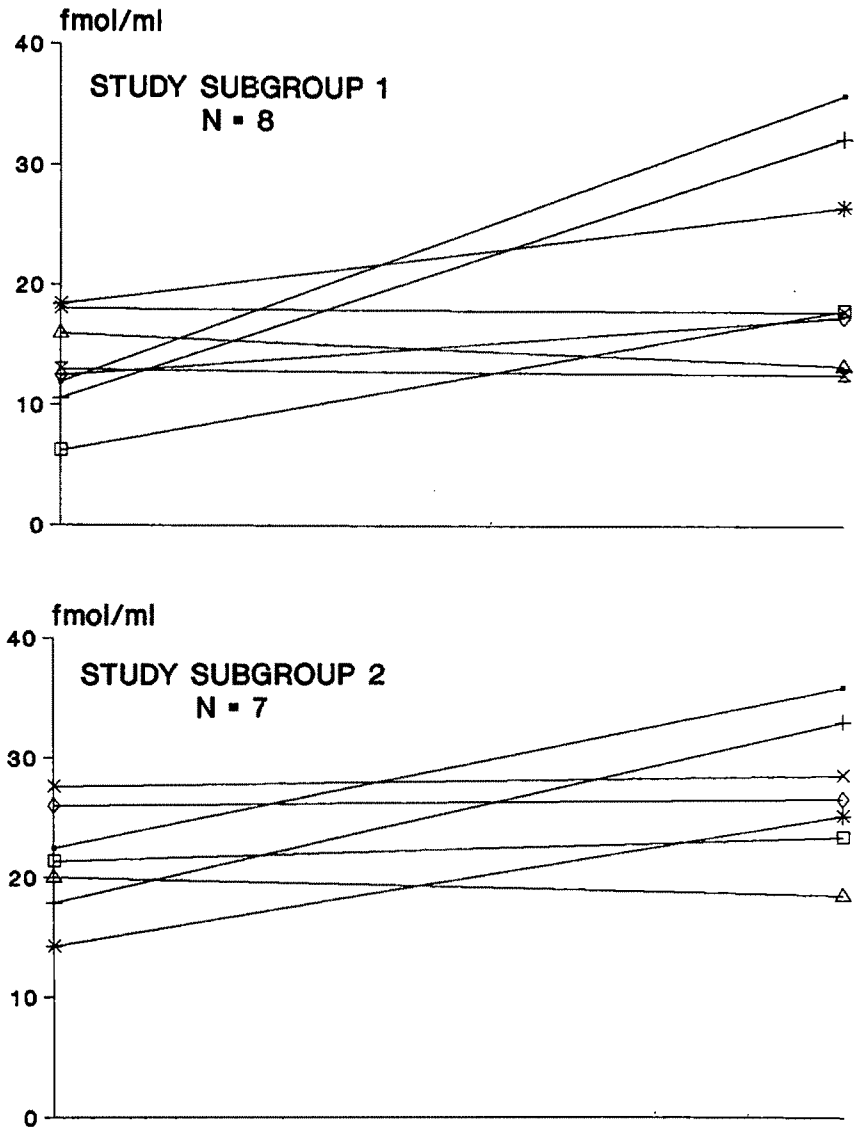

Fig. 2. Serum endothelin-1 levels of 15 study group patients measured 6 to 10 weeks after delivery compared with their levels during acute hypertensive phase before delivery. *Study Subgroup 1*, Chronically hypertensive women. *Study Subgroup 2*, Preeclamptic women.

enzyme immunoassay and radioimmunoassay kit, respectively. Our findings are in accordance with these recently reported results and suggest that serum levels of endothelin-1 are significantly decreased during normal pregnancy and that preeclamptic toxemia of pregnancy is associated with serum levels that are significantly higher than those in a normal pregnancy. However, we could not demonstrate, in our group of preeclamptic patients, a correlation of the circulating endothelin-1 levels to the severity of the disorder.

High levels of circulating endothelin-1 may reflect increased synthesis or reduced elimination of the peptide. An increase in endothelial production in patients with preeclamptic toxemia might be a feedback-related outcome of interaction with prostacyclin and endothelium-derived relaxing factor synthesis.[10-12, 19, 20] Thus the more disturbed the prostaglandin and platelet metabolism, the more increased the synthesis and release of endothelin-1 by endothelial cells. Such a feedback mechanism might be regulated by signals derived from intracellular calcium stores and protein kinase C activation, a recently proposed cellular action site of endothelin-1.[21] Because endothelin-1 is produced from preproendothelin, the activity of the converting enzyme that controls the release of the immunoreactive endothelin-1 peptide and the expression of the preproendothelin-1 messenger ribonucleic acid may be targets for the proposed feedback mechanism. Alternatively, the differences in levels of circulating endoth-

elin-1 might be explained by a structural or functional alteration in the vascular receptors for this peptide, which has already been identified in the human placenta.[22]

The basic pathophysiologic characteristics of chronic hypertension in pregnancy are obviously different from those of preeclamptic toxemia and probably more closely resemble those of essential hypertension. Our findings regarding the low endothelin-1 levels of the chronically hypertensive pregnant patients are not in accordance with the relatively high circulatory endothelin-1 levels reported by others in nonpregnant patients with essential hypertension. We thus assume that the pregnancy-reducing effect on the endothelin-1 synthesis contradict and conceal the hypertensive effect in cases of chronic hypertension in pregnancy. It should be noted that although the patients designated here as chronically hypertensive were admitted because of an aggravated hypertensive state during pregnancy, their low endothelin-1 levels resemble those of the normal pregnant patients and not those of the patients designated as preeclamptic. These results accentuate the differences between chronic hypertension and preeclamptic hypertension in pregnancy and may reflect the possible role of endothelin-1 in the pathogenesis of the systemic vascular abnormality of the preeclamptic syndrome.

The results of this preliminary study show that circulatory immunoreactive endothelin-1 levels decline during normal pregnancy relative to their levels in nonpregnant women but increase significantly during preeclamptic illness. Enhanced endothelin-1 production may be associated with the etiology of preeclampsia or rather may be the result of local hormonal feedback mechanisms involving the endothelium.

We thank Mr. Efraim Kriel for his generous assistance with this study.

Platelet activation and vascular damage in gestational hypertension

Veronique C. Ballegeer, MD,[a] Bernard Spitz, MD, PhD,[b] Luc A. De Baene, MD,[a] Andre F. Van Assche, MD, PhD,[b] Melanie Hidajat, MD,[c] and Arnold M. Criel, MD[c]

Brugge and Leuven, Belgium

Increased plasma fibronectin levels are a highly sensitive and specific predictor of gestational hypertension. Of a total of 105 apparently healthy normotensive primigravid women seen at the outpatient clinic, 10 with increased plasma levels of fibronectin (mean ± 2 SD), were compared with 14 controls. Parameters of early vascular damage (laminin, preprocollagen III), platelet activation (β-thromboglobulin, platelet factor 4), and coagulation (thrombin–antithrombin III complexes, fibrinopeptide A) were measured at regular (weekly or monthly) intervals. Abnormal values of laminin ($p < 0.005$) and fibronectin ($p < 0.0001$) were found up to 4 weeks before the onset of clinical disease. Levels of β-thromboglobulin ($p < 0.0001$) were also elevated at least 4 weeks before the appearance of clinical symptoms. Our results show that increased levels of laminin, fibronectin, and platelet activation, as indicated by β-thromboglobulin levels, are preclinical features of gestational hypertension and indicate that vascular damage has occurred. Fibrin formation would appear to occur later. (Am J Obstet Gynecol 1992;166:629-33.)

Key words: Fibronectin, laminin, β-thromboglobulin, preeclampsia

The etiology of hypertensive disease in pregnancy remains enigmatic. A variety of different pathogenic pathways may lead to hypertension, which in some cases is associated with chronic consumptive coagulopathy. Endothelial and subendothelial cell damage may induce platelet activation or may directly liberate tissue factor,[1] a cofactor initiating the extrinsic coagulation pathway. The inability to limit the extent of platelet activation, as a result of a reduction of the prostacyclin-to-thromboxane A_2 ratio[2] and a reduction of the fibrinolytic capacity, may aggravate the continuing coagulopathy.[3] Another blood platelet containing vasoactive substances such as serotonin have a dramatic influence on blood pressure.[4]

Fibronectin, laminin, and preprocollagen III are parameters related to endothelial cell damage. Fibronectin, an adhesive glycoprotein, is produced by fibroblasts, endothelial cells, macrophages, and thrombocytes[5] and is a widespread component of connective tissue and basement membranes. It is involved in many functions, such as cell adhesion, cell motility, tissue repair, opsonization, and coagulation.[6] Increased plasma fibronectin levels in pregnant women predict the development of gestational hypertension with a sensitivity and specificity of 95% and precede the onset of clinical symptoms, on average, by 4 weeks.[7, 8] Laminin is synthesized by endothelial cells and is a major intrinsic component of the basement membrane. Preprocollagen III is a marker for both synthesis and mobilization of type III collagen, a constituent of the extracellular matrix.[9-11]

Measurement of plasma levels of β-thromboglobulin and platelet factor 4, two secreted platelet proteins, allows the detection of in vivo platelet activation and the distinction with artifactual in vitro release.[12, 13]

Elevated plasma levels of fibrinopeptide A, a cleavage product of the α-chain of fibrinogen and of thrombin–antithrombin III complexes, are indices of thrombin and fibrin generation.[14]

In the current study, with increased plasma fibronectin used as an early predictor of the development of gestational hypertension, we investigated the time course of changes in plasma levels of the above-mentioned proteins, in an attempt to define the sequence of pathologic events leading to the clinical picture.

Material and methods

A total of 105 apparently healthy normotensive primigravid women, seen at the outpatient clinic of the Department of Obstetrics between September 1988 and June 1989, were prospectively included in the study after giving informed consent. The nature of the study was explained in detail and none of the subjects who were requested to participate declined.

Blood pressure was measured in the sitting position. Diastolic pressure was defined as the pressure at which a Korotkoff phase V was obtained. Blood pressure was

measured before 20 weeks of pregnancy, monthly between 20 and 32 weeks, every 2 weeks between 32 and 36 weeks, and then weekly until delivery. Gestational hypertension was defined as a diastolic blood pressure of >90 mm Hg on at least two occasions during the second half of pregnancy in a previously normotensive woman. Preeclampsia was defined as increased diastolic blood pressure and a proteinuria of 0.3 gm/day (International Society for the Study of Hypertension in Pregnancy).[15]

Management of the subjects was determined on the basis of clinical signs and was not altered on the basis of the results of blood analyses. Blood samples for fibronectin were taken three times during pregnancy at 28, 32, and 36 weeks. In 10 patients, where the level of fibronectin was >450 μg/ml (mean ± 2 SD), additional blood samples for laminin, preprocollagen III, β-thromboglobulin, platelet factor 4, thrombin–antithrombin III complexes, and fibrinopeptide A were taken 2 weeks later and then weekly until development of clinical symptoms of gestational hypertension. Fourteen patients, selected at random, without any rise of plasma fibronectin level and who remained normotensive during pregnancy were taken as controls. The subjects were asked to refrain from aspirin intake during the study.

All blood samples were drawn from fasting subjects without stasis before 10 AM, by venipuncture, after a rest period of at least 10 minutes. For β-thromboglobulin and platelet factor 4, blood was mixed 9:1 in special tubes (Diatubes-H, Stago, France) containing a mixture of theophylline, adenosine, and dipyridamole. Samples were immediately mixed and kept on ice until centrifugation for 30 minutes, at 2500g at 4° C. The supernatant was transferred in plastic tubes with a plastic pipette and stored at −20° C. All tests were performed within 30 days after sampling with enzyme-linked immunosorbent assay (ELISA, Stago). For fibronectin, laminin, preprocollagen III, and thrombin–antithrombin III complexes, the blood was anticoagulated with buffered citrate (nine parts of blood were mixed with one part of sodium citrate, 38 mg/ml) and centrifuged for 10 minutes at 2500g at 4° C.

Fibronectin was measured by the Mancini immunodiffusion technique with commercial plates from Behringwerke (Marburg Lahn, West Germany). The level of plasma fibronectin throughout normal pregnancy was 330 μg/ml or 100%, the cutoff point is taken at 450 μg/ml or 140% (mean ± 2 SD).[8] Laminin and preprocollagen III were determined by commercial radioimmunoassay kits and thrombin–antithrombin III complexes with an enzyme-linked immunosorbent assay test also purchased from Behringwerke. If not analyzed immediately, the samples were stored at −20° C. For measurement of fibrinopeptide A an enzyme-linked immunsorbent assay test from Stago was used. Blood for fibrinopeptide A was quickly collected in a special anticoagulation solution containing citrate, heparin, and a protein-specific inhibitor, rapidly centrifuged for 10 minutes at 2500g and treated with ben-

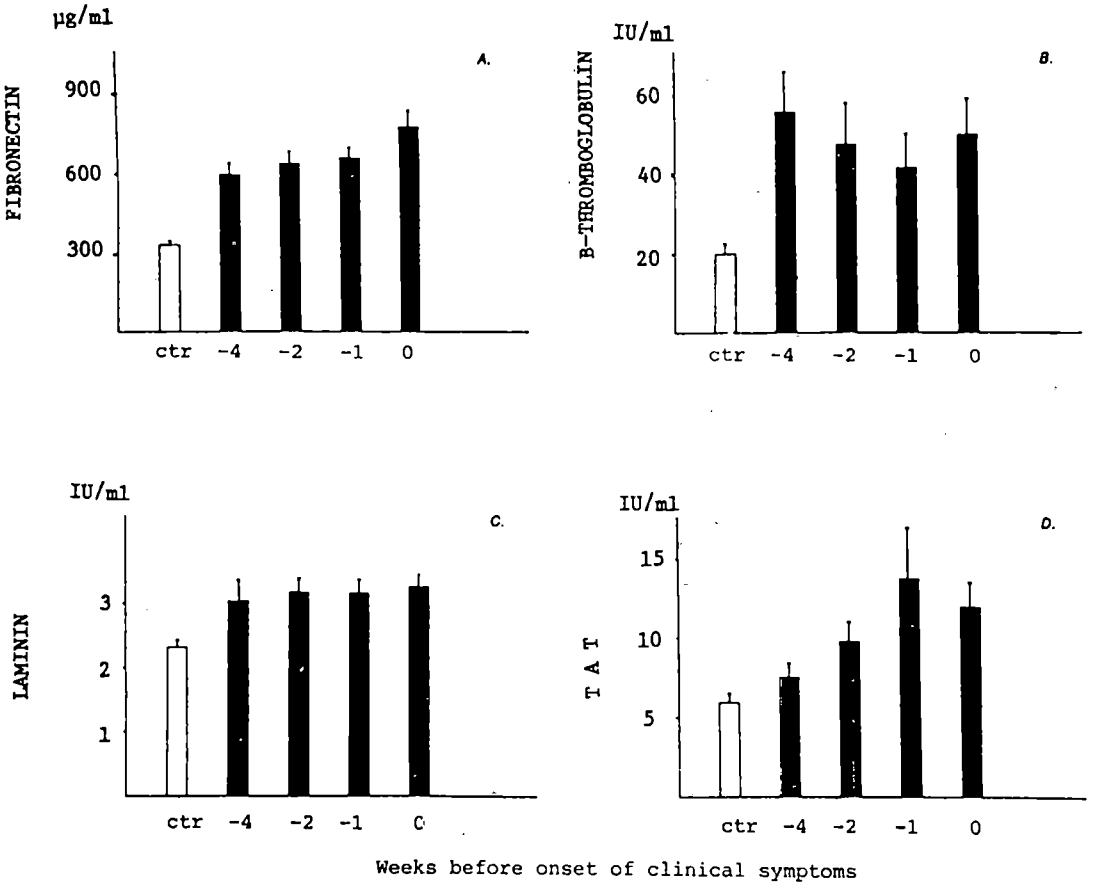

Fig. 1. Plasma levels of fibronectin **(A)**, β-thromboglobulin **(B)**, laminin **(C)**, and thrombin–antithrombin III complex *(TAT)* **(D)** during 30 to 40 weeks of pregnancy in 14 normotensive women (control group) and in 10 women in whom gestational hypertension developed at weeks −4, −2, and −1 before clinical symptoms and at diagnosis *(0)* of gestational hypertension. Results in columns represent means; *bars*, SEM.

tonite (1 ml plasma with 0.5 ml bentonite centrifuged at 1400*g* for 10 minutes and stored −20° C). The Mann-Whitney rank-sum test was used to determine the differences between the groups. Correlation between different parameters were measured with the Spearman test.

Results

Ten of the 105 initially normotensive primigravid women had elevated fibronectin plasma levels, >450 µg/ml, which is two standard deviations above the mean. Seven of the 10 patients had a significant fibronectin rise later than 32 weeks. Of those 10 patients, eight had severe preeclampsia with proteinuria, two had gestational hypertension, and none had eclampsia or severe coagulation defects. The 95 with normal fibronectin levels remained normotensive.

Table I summarizes the results of blood pressure, plasma levels of fibronectin, laminin, and preprocollagen III, plasma levels of β-thromboglobulin and platelet factor 4, plasma levels of fibrinopeptide A, thrombin–antithrombin III complexes, and platelet count and hematocrit at regular intervals in the third trimester of the women in whom gestational hypertension developed, compared with the normotensive controls. At the moment of clinical disease (time = 0) all the studied parameters of endothelial damage, platelet activation, and coagulation were significantly different compared with the control group. The hematocrit was also higher, but we did not find a significant difference in platelet count. When diagnostic category was subdivided, levels of fibronectin (565 ± 7 vs 848 ± 182 µg/ml) and laminin (2.9 ± 0.18 vs 3.39 ± 0.68 IU/ml) were higher in the preeclampsia with proteinuria ($n = 8$) versus the nonproteinuria group ($n = 2$).

Four weeks before clinical symptoms (compared with the control group), significant increases in plasma levels of fibronectin ($p < 0.0001$) and laminin ($p < 0.05$), which are parameters of early vascular damage, and β-thromboglobulin and platelet factor 4 ($p < 0.005$), which are indices of platelet activation, were found (Fig. 1). Of the parameters of coagulation, thrombin–

antithrombin III complexes were significantly raised 2 weeks later ($p < 0.005$), whereas a steady but not significant increase was found for fibrinopeptide A. Preprocollagen III was significantly increased only 1 week before symptoms ($p < 0.01$). In the group who finally became hypertensive, we found a significant correlation ($p < 0.01$) between fibronectin and diastolic blood pressure ($r = 0.994$), laminin ($r = 0.974$), fibrinopeptide A ($r = 0.994$), and preprocollagen III ($r = 0.970$). No such correlations were found in the control group.

Comment

Gestational hypertension is a rather common complication of pregnancy, peculiar to humans and affecting both maternal and fetal health. Its cause and pathogenesis remain enigmatic and controversial. In established preeclampsia, platelet activation and chronic coagulopathy, which enhance the gravity of the symptoms, have been well characterized.[16]

Recently, however, the role of endothelial cell damage in the development of the clinical and biochemical features of the disease has been stressed.[17] Although the mechanism is not fully understood, it would be interesting to find early ways of measuring this damage. A predictive marker would indeed be of clinical value particularly for the timely start of a prophylactic treatment and for the evaluation of the progress of the disorder.

In the current study we prospectively analyzed women in whom hypertension ultimately developed. They showed an early rise, at least 4 weeks before the onset of clinical symptoms, of fibronectin, laminin, and later preprocollagen type III. An increase in plasma fibronectin levels correlates well with the increase of other basement membrane proteins, such as laminin and preprocollagen III, indicating a continuous process. These changes are compatible with endothelial cell damage, causing exposure of the basement membrane and the subendothelium. In response to this injury platelets are activated and adhere to subendothelial structures, such as collagen III and laminin. The simultaneous significant rise of β-thromboglobulin and, to a lesser degree, of platelet factor 4 found in the study indicates platelet activation and release of the contents of the α-granules. The release of the vasoconstrictor thromboxane A_2 by the damaged endothelial cells, together with the release of vasoactive substances such as serotonin and others, by the α-granules of platelets could be responsible for the onset of hypertension. Higher levels of urinary metabolites of thromboxane A_2 have also been described in a preclinical stage.[18] These activated platelets may cause vasoconstriction and activate coagulation. Finally, signs of fibrin formation occurred somewhat later; there was a significant rise of the thrombin–antithrombin III complexes from week −2. There was a steady but nonsignificant rise of fibrinopeptide A, however, with a significant correlation of fibrinopeptide A with the fibronectin level. This discrepancy may be explained partly by the high standard deviation. The absence of correlation between thrombin–antithrombin III complexes and fibronectin and the nonsignificant rise of fibrinopeptide A might be the result of the low degree of severity of the disease in most patients, as other authors have clearly found a positive correlation between plasma antithrombin III activity and the degree of severity of preeclampsia and eclampsia.[19] This secondary activation of the coagulation, combined with a decrease of fibrinolysis and impaired fibrin clearance, will obviously interfere with the microcirculation of the placenta, liver, central nervous system, and kidneys.

Our study indicates that indices of endothelial damage and platelet activation antedate parameters of coagulation and the clinical onset of symptoms in gestational hypertension. They offer possibilities of early diagnosis and assessment of therapeutic approaches aimed at limiting vascular damage and platelet activation.

We thank Rita Ghevaert and Ria Matton, who performed the tests, and the medical staff and midwives of the obstetric department at A.Z. Sint-Jan.

Human monoclonal antibody recognizing an antigen associated with ovarian and other adenocarcinomas

Lloyd H. Smith, MD, PhD,[a]* Amy Yin, MD,[b] Michelle S. Glasky, PhD,[b] Nancy Tyler, PhD,[c] Mariana Robles, MS,[c] Chris A. Foster, BS,[a] Marcia Bieber, MD,[b] and Nelson N.H. Teng, MD, PhD[b]

Davis and Stanford, California

MS2B6, a human monoclonal antibody derived from a patient with advanced ovarian cancer, has been used to study the distribution and characteristics of its target antigen. The MS2B6 antigen was detected by immunoperoxidase studies in 41 of 41 epithelial ovarian cancers and in the majority of nonovarian adenocarcinomas. Among normal tissues the MS2B6 antigen was found in the adult epithelia of the fallopian tube, endometrium, endocervix, colon, bronchus, breast, sweat duct, and large renal ducts. No detectable antigen was found in peritoneal epithelia, tissue stromal cells, spleen, thymus, or blood-borne cells. Immunoblotting analysis showed that the MS2B6 epitope resides on polypeptides of 38, 44, and 60 kd. The cellular location of the MS2B6 antigen was studied with immunoperoxidase and immunofluorescent staining and immunoelectronmicroscopy of ovarian cancer ascites tumor cells. The results suggest that in ascites tumor cells the MS2B6 antigen is located in a layer of the peripheral cytoplasm beginning just below the cell membrane. MS2B6 may be useful as an imaging or therapeutic agent. (AM J OBSTET GYNECOL 1992;166:634-45.)

Key words: Human monoclonal antibodies, ovarian cancer, immunoperoxidase

The advent of mouse monoclonal antibody (MAb) technology has provided a long list of potentially useful reagents for diagnosis, treatment, and management of clinical problems in obstetrics and gynecology.[1] For example, CA 125 is an ovarian cancer–associated antigen detected by mouse MAb OC 125, which has been extensively studied.[2] Although the usefulness of OC 125 in screening for asymptomatic ovarian cancer remains uncertain,[3] it has an established role in several areas of gynecology, including triage of patients with pelvic masses[4] and management of most patients with nonmucinous epithelial malignancies of the ovary.[5] OC 125 has emerged as one of the best examples of the potential utility of monoclonal antibody reagents in clinical medicine. However, limitations are recognized; when mouse MAbs are administered in vivo to patients, the result is often a human antimouse antibody (HAMA) response. The HAMA response occurs more frequently after multiple administrations of mouse MAbs[6]; it may occur in spite of immunosuppressive therapy[7] and may cause adverse clinical sequelae or an abrogation of the intended diagnostic or therapeutic effect.[8,9] In the case of mouse MAb OC 125, a HAMA response was detected in three of seven patients given intravenous injection of radiolabeled OC 125 for imaging and six of eight patients given radiolabeled OC 125 for therapy.[10] Furthermore, patients once exposed to mouse MAb may be ineligible for subsequent clinical trials with other mouse MAbs because the presence of HAMA can affect mouse MAb metabolism. The presence of HAMA can also interfere with certain laboratory tests based on mouse MAb technology.

Because of the HAMA phenomenon interest has increased in the development of genetically engineered chimeric human-mouse MAbs[11] and the generation of human MAbs to cancer-associated antigens.[12] The study of human MAbs directed toward antigens associated with cancer cells may not only provide potentially useful MAbs reagents that are presumably less immunogenic for humans than mouse MAbs, they may also allow an improved understanding of the human immune response to malignancy. In fact, the humoral immune response to cancer-associated antigens can be directly studied in detail with human MAbs and can only be indirectly approached with cancer-associated antigens detected by mouse MAbs.

We have previously described an efficient method of screening human MAbs produced by Epstein-Barr vi-

rus–transformed patient lymphocytes for binding to purified ovarian cancer ascites tumor cells.[13] MS2B6 is a human monoclonal immunoglobulin M (IgM) (μ, λ) derived from lymphocytes from a patient with serous papillary ovarian carcinoma. Here we describe the preliminary characterization of the MS2B6 antigen, including its tissue distribution, molecular characteristics, and cellular location.

Material and methods

Purification and labeling of MS2B6 IgM. Derivation of human hybridoma MS2B6 has been described previously.[13] In brief, splenocytes from a patient with stage III ovarian cancer were obtained from splenic tissue removed at tumor debulking. These lymphocytes were Epstein-Barr virus transformed and grown at 1000 cells per well; after 3 weeks supernatants were screened for binding to ovarian cancer ascites tumor cells. Lymphocytes from a positive well were fused with heteromyeloma SHM-D33, and hybrid cells were selected. A hybridoma line that secreted the MS2B6 IgM was identified. The cell line was easily adapted for growth in serum-free medium (Iscoves with 1% Nutridoma-NS, Boehringer-Mannheim, Indianapolis) and continued to produce IgM at a rate of 32 μg per 10^6 cells per day. Supernatant fluids containing approximately 60 μg/ml IgM were concentrated 100-fold by ultrafiltration with a membrane with 300,000 d molecular weight cut-off

(Amicon, Beverly, Mass.). The MS2B6 IgM was purified by high-pressure ion exchange chromatography with a liquid chromatograph (model 1084B, Hewlett Packard, Palo Alto, Calif.) and a 0.75 × 7.5 cm TSK-DEAE-5PW column (Bio Rad, Hercules, Calif.). In brief, buffer A consisted of 0.02 mol/L Tris, 0.1 mol/L sodium chloride, pH 8.5; buffer B consisted of 0.02 mol/L Tris, 0.6 mol/L sodium chloride, pH 7.0. Samples were applied to the column, which had been equilibrated with 10% buffer B in buffer A; the IgM was eluted by changing to 25% buffer B. The column was washed with 100% buffer B and finally 10% buffer B for regeneration. The eluted IgM was concentrated and stored frozen in liquid nitrogen. The purity of the final product was approximately 95% IgM by sodium dodecyl sulfate–polyacrylamide gel electrophoresis (SDS-PAGE).

Biotin labeling was by the method of Haspel et al.[14] with modifications. High-pressure ion exchange chromatography–purified MS2B6 IgM or control IgM (purified human serum IgM, Cappel, Durham, N.C.) at 1 mg/ml was dialyzed versus 0.01 mol/L potassium phosphate and 0.15 mol/L potassium chloride, pH 7.8. Biotin: *N*-hydroxysuccinimide (Sigma Chemical Co., St. Louis) dissolved at 2 mg/ml in dimethylsulfoxide was added to give a molar ratio of biotin to IgM of 30:1 (with a molecular weight for monomer IgM of 180,000 d). After 15 minutes at room temperature with agitation, 0.1 vol 1 mol/L ammonium chloride was added and the solution dialyzed versus phosphate-buffered saline solution with 0.02% sodium azide.

Immunoperoxidase studies. Procurement of human tissues had the approval of the Human Subjects Committee at Stanford University and University of California–Davis School of Medicine and was obtained after surgery or autopsy through the Departments of Surgical Pathology. Pathology reports on each malignant tissue were reviewed. The fresh tissues were cut into small pieces, wrapped in foil, and stored in liquid nitrogen until immediately before transfer to embedding medium. Six-micron cryostat sections were air dried and stored at 4° C, then fixed immediately before use with PLP fixative[15] (0.5% paraformaldehyde, 0.075 mol/L L-lysine, and 0.01 mol/L sodium periodate) for 10 minutes at 4° C followed by washing in phosphate-buffered saline solution. Some tissues required blocking of endogenous biotin as described elsewhere.[16] Suppression of endogenous peroxidase activity was performed as described elsewhere.[17] Immunoperoxidase staining with biotin-labeled MS2B6 IgM or control IgM was performed in the standard manner,[18] in brief as follows: The sections were sequentially incubated (with phosphate-buffered saline solution washing between incubations) with 10% fetal calf serum to block, biotin-labeled antibody at 25 μg/ml, streptavidin-HRP (Sigma) at 0.5 μg/ml, then diaminobenzidine (DAB, Sigma) at 1 mg/ml in 0.1 mol/L Tris pH 7.2 with 0.03% hydrogen peroxide. After 15 minutes slides were washed with water, counterstained with hematoxylin, and covered with coverslips. Microscopically, positive staining by biotin-labeled MS2B6 IgM was visualized as deposition of brown stain on cells not stained by biotin-labeled control IgM.

Electrophoresis and immunoblotting. SDS-PAGE was performed with the discontinuous buffer system of Laemmli,[19] with 4% stacking and 10% running gels. Samples consisted of purified ovarian cancer ascites tumor cells or ovarian cancer cell line 2774. Preparation of the ascites tumor cells is described below. The ovarian cancer cell line 2774 was grown to confluence in Dulbecco's modified Eagle's medium with 10% fetal calf serum, scraped off the flasks, and washed in phosphate-buffered saline solution. Sodium dodecyl sulfate sample buffer containing 2-mercaptoethanol was added (20 μl/10^6 cells) and the samples heated to 100° C for 3 minutes. Human IgM (2 μg) was run in control lanes to confirm transfer after immunoblotting.

Blotting onto nitrocellulose paper was as described by Towbin et al.[20] The blots were blocked by incubation in 4% nonfat milk in phosphate-buffered saline solution for 1 hour at room temperature. Indirect immu-

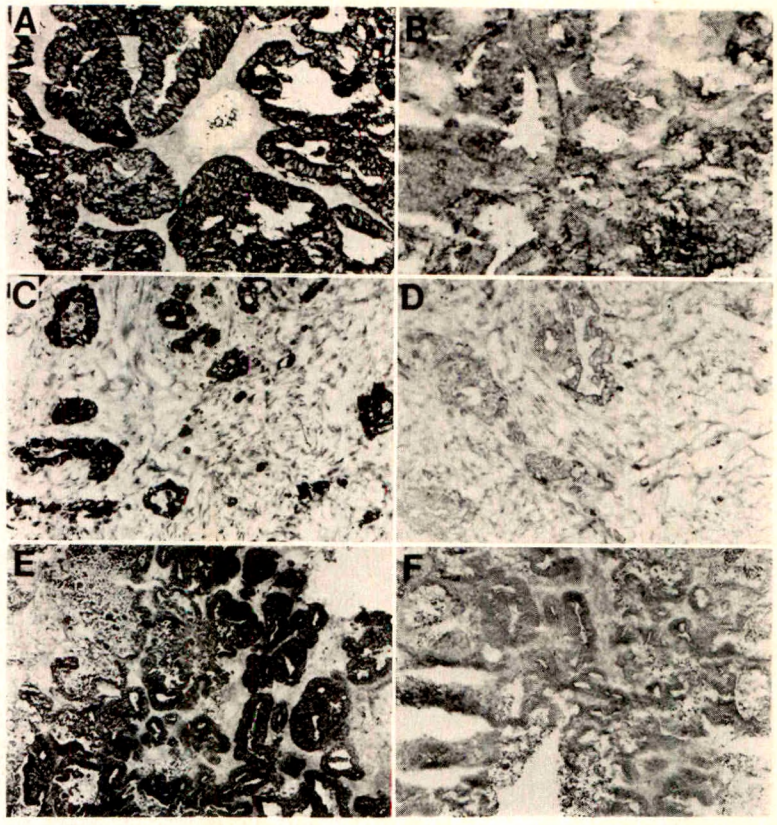

Fig. 2. Distribution of MS2B6 target antigen in nonovarian adenocarcinoma tissues. **A,** Moderately differentiated endometrial carcinoma (Biotin-labeled MS2B6 stain; ×200); **B,** Same tissue as **A** (Biotin-labeled negative control IgM stain); **C,** Metastatic pancreatic carcinoma (Biotin-labeled MS2B6 stain; ×200); **D,** Same tissue as **C** (Biotin-labeled negative control IgM stain); **E,** Colon carcinoma (Biotin-labeled MS2B6 stain; ×200); **F,** Same tissue as **E** (Biotin-labeled negative control IgM stain).

nostaining was performed by the alkaline phosphatase method[21] as modified by Sidberry et al.[22] Unlabeled MS2B6 or control IgM (human serum IgM, Cappel) were incubated with the blot at 5 to 10 μg/ml for 4 hours followed by PBS washing. Next the blots were incubated with alkaline phosphatase–labeled goat antihuman IgM (1:200, Sigma) for 2 hours, washed in phosphate-buffered saline solution, then placed in 50 mmol/L Tris, pH 8.3. Freshly prepared chromagen solution (Naphthol AS-MX phosphate 1 mg/ml, Fast Red TR salt 2 mg/ml, both from Sigma, in 50 mmol/L Tris, pH 8.3) was added and incubation continued until color development was achieved. The blots were then washed with water and air dried.

Immunolocalization experiments. Three ovarian cancer ascites tumor cell preparations purified by Percoll buoyant centrifugation[13] were used for the immunoperoxidase studies. Tumor cells were either fixed in the PLP fixative (as described above) or in methanol-acetone (1:1) for 10 minutes at 4° C. Fixed cells were reacted with biotin-labeled MS2B6 or biotin-labeled control IgM, washed, reacted with streptavidin-peroxidase, and developed with DAB as described in the immunoperoxidase tissue studies. After washing, the cells were fixed with 2% glutaraldehyde in phosphate-buffered saline solution for 30 minutes at room temperature to stabilize the DAB-stained cells. The cells were subsequently stained with 2% osmium tetroxide for 30 minutes, dehydrated in alcohol, equilibrated with propylene oxide, infiltrated with epoxy (Polybed 812, Polysciences, Warrington, Pa.), and polymerized at 60° C. Two-micron sections were obtained for microscopy without further counterstaining. For immunoelectronmicroscopy, the methanol-acetone–fixed, epoxy-embedded cell blocks were sectioned at 80 to 100 nm with an ultramicrotome (Reichert, model OMU3, American Optical, Southbridge, Mass.) mounted on 200 mesh copper/palladium grids. To maximize the contrast of the DAB deposits, these sections were not counterstained further. The grids were viewed with a Philips electron microscope. Photographs were printed from negatives to give identical contrast levels.

Immunofluorescence studies were performed with ovarian cancer ascites tumor cell preparations that had

been cryopreserved. After the cells were thawed and washed, they were reacted with biotin-labeled MS2B6 or biotin-labeled control IgM. Subsequently the cells were washed and reacted with streptavidin-fluorescein isothiocyanate (Sigma) in phosphate-buffered saline solution and washed and viewed by ultraviolet microscopy. Where indicated, propidium iodide (Sigma) 1 μg/ml was included in the final wash buffer.

CA 125 immunoassay. An enzyme-linked immunoassay for ovarian cancer–associated antigen CA 125 was performed according to the insert in the test kit (Abbott Laboratories, Abbott Park, Ill.). To 100 μl of CA 125 standard (168 U/ml) were added aliquots of OC 125 (gift of R. Knapp) or MS2B6. After subsequent incubation with OC 125–beads and OC 125–peroxidase conjugate, the beads were washed and developed and optical density measurements were obtained (495 nm).

Results

Tissue distribution of MS2B6 antigen. To maximally preserve native antigen structures for immunoperoxidase studies, frozen sections were used. Fixation of the sections with PLP allowed adequate tissue preservation and antigen staining. Forty-one different ovarian epithelial cancer tissue samples were stained for biotin-labeled MS2B6 binding. As shown in Table I, 41 of 41 specimens stained positively, including 30 serous papillary, 4 mucinous, 6 endometrioid, and 1 clear-cell tumor. The single example of a borderline mucinous tumor from a patient with pseudomyxoma peritonei demonstrated marked heterogeneity of expression of MS2B6 antigen with weak, patchy staining. Heterogeneous expression of the antigen was absent or minimal in the other tissues examined, which showed remarkable uniformity in staining. Fig. 1 demonstrates the pattern of staining for ovarian carcinoma tissues. Among the serous carcinomas, positive staining was independent of tumor grade.

Forty-five different nonovarian or nonepithelial ovarian malignant tissues were examined for MS2B6 antigen staining (Table II). Eight examples of squamous cell carcinoma, 5 sarcomas, and 2 of 3 ovarian germ cell cancers were negative for MS2B6 antigen expression. One ovarian immature teratoma did have positive staining, but only in areas of mature, benign epithelium. The majority of 20 nonovarian adenocarcinomas, including 5 of 10 endometrial adenocarcinomas and five of five colon adenocarcinomas stained positively for MS2B6 antigen (Fig. 2). In addition, one of three undifferentiated carcinomas (unknown primary), a mesothelioma (peritoneum), and a transitional cell carcinoma (kidney) stained positively. Examples of malignant melanoma and lymphoma stained negatively.

Seventy-three different normal adult- and fetal-tissue specimens were examined for MS2B6 antigen staining (Table III). Positive staining was found among certain normal nonsquamous epithelia, including fallopian tube, endocervix, endometrium, bronchus, colon, mammary ducts, large renal ducts, salivary glands, sweat ducts, and bladder. Weak, patchy staining among normal tissues was noted in single examples of liver, thyroid, and small bowel epithelium. The strongest and most uniform staining was of fallopian tube, endometrial, and bronchial epithelia (Fig. 3).

Several tissues, including kidney, liver, and colon, demonstrated significant staining of epithelia when the biotin-labeled negative control IgM preparation was used to stain the tissues. In the case of liver the vast majority of this background binding was removed by blocking for endogenous biotin activity. Even after the blocking of endogenous biotin, several specimens of colon epithelium demonstrated significant binding of negative control biotin-labeled IgM, although binding of biotin-labeled MS2B6 was always more intense. Most of this background control IgM staining of colon epithelium could be removed by blocking for endogenous

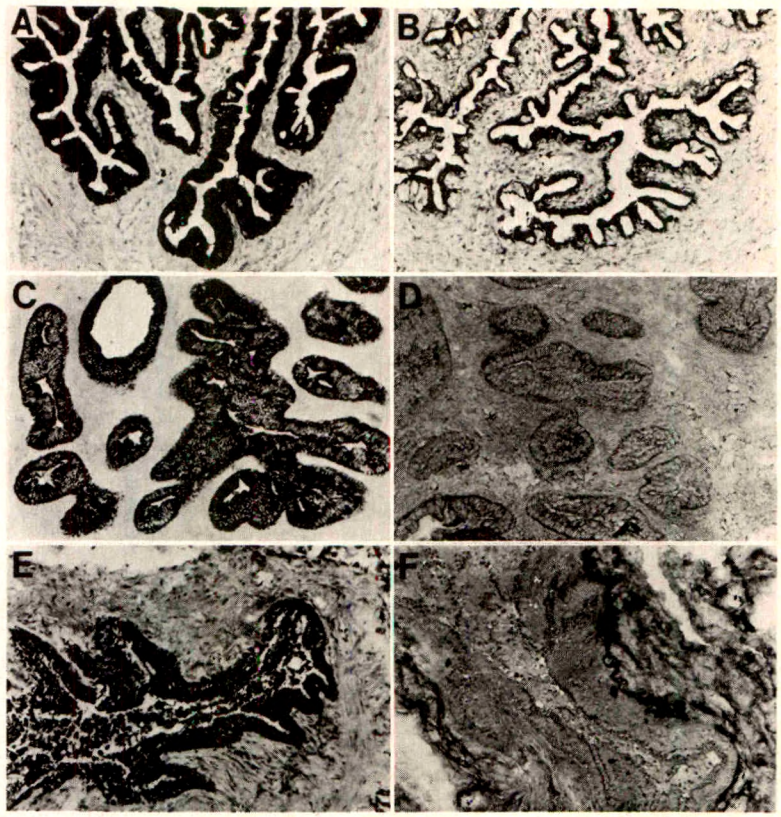

Fig. 3. Distribution of MS2B6 target antigen in normal adult epithelia. **A,** Fallopian tube (Biotin-labeled MS2B6 stain; ×200); **B,** Same tissue as **A** (Biotin-labeled negative control IgM stain); **C,** Endometrium (Biotin-labeled MS2B6 stain; ×200); **D,** Same tissue as **C** (Biotin-labeled negative control IgM stain); **E,** Bronchus (Biotin-labeled MS2B6 stain; ×200); **F,** Same tissue as **E** (Biotin-labeled negative control IgM stain).

peroxidase. A similar phenomenon was observed for several specimens of kidney epithelium. Here, MS2B6 staining was weak and generally confined to the epithelium of large ducts, with glomeruli being totally negative. Control IgM staining of kidney specimens resulted in a similar but even less intense pattern, even after blocking the endogenous biotin.

The absence of the MS2B6 antigen from peritoneal and ovarian epithelia deserves note. In addition, the antigen was not detected among epidermoid epithelia except in the sweat gland ducts in the skin. Among fetal tissues the antigen was intensely expressed in examples of syncytiotrophoblast epithelium and in fetal intestinal, hepatic, and renal epithelia. Six specimens of benign lesions were negative for MS2B6 antigen, including 2 benign ovarian cysts, 2 uterine leiomyomas, 1 ovarian fibroma, and 1 hydatidiform mole. Two of three cases of endometriosis stained positively.

In addition to the absence of MS2B6 staining of normal spleen and thymus, other lymphoid collections such as those located in intestinal submucosa stained negatively. Among all tissues examined, intravascular elements always stained negatively for MS2B6 staining. To independently test for MS2B6 binding to elements of the blood (e.g., red blood cells, lymphocytes, granulocytes, platelets), further tests were performed. MS2B6 at 50 μg/ml was tested by the Stanford Transfusion Service with standard hemaagglutination techniques. MS2B6 failed to react with a panel of red blood cells expressing the following antigens: blood group antigens A and B; Rh antigens D, C, c, E, and e; Kell antigens K, k, Kp^b, and Js^b; Duffy antigens Fy^a and Fy^b; Kidd antigens Jk^a and Jk^b; Lewis antigens Le^a and Le^b; P antigen; MN antigens M, N, S, and s; Lutheran antigens Lu^a and Lu^b; and $X^a{}_g$ antigen. MS2B6 (at 50 μg/ml) was also tested for granulocyte agglutination and for cytotoxicity to granulocytes, lymphocytes, and platelets based on a carboxyfluorescein diacetate uptake technique.[23] Four different granulocyte specimens were negative for MS2B6-induced aggregation or cytotoxicity. Four different lymphocyte specimens and six different platelet preparations showed no MS2B6-induced cytotoxicity.

Western blot analysis. Western blot analysis of whole cell extracts of both purified ascites cells and ovarian

cancer cell line 2774 consistently revealed several MS2B6-staining bands not observed in blots stained with negative control IgM (human serum IgM) (Fig. 4). The major components consisted of bands of approximately 38 and 44 kd. Although some heterogeneity was apparent, the 38 kd species was the prominent band among ascites tumor cell preparations. In some preparations a 60 kd band was present, but this band was less intense than the 38 or 44 kd bands and was seen inconsistently. None of these bands appeared after staining identical blots for control IgM binding.

Cellular localization of MS2B6 antigen. Ovarian cancer ascites tumor cells were chosen for these studies to achieve improved resolution over that obtained in the tissue frozen-section studies. Previous immunofiltration studies with cryopreserved ascites tumor cells suggested the possibility that MS2B6 was reacting to an antigen on the tumor cell surface. Two methods of fixation were chosen. The PLP fixative was chosen to preserve the integrity of the cell membranes, and the methanol-acetone fixative was used to permeabilize the cells, allowing cell entry of the MS2B6 IgM molecule. MS2B6-stained tumor cells had a dark ring around the cell periphery (Fig. 5). The pattern suggested the possibility of surface staining, but many more cells stained after methanol-acetone fixation (91%) than after PLP fixation (31%), a finding more consistent with an intracellular location of the MS2B6 antigen.

Immunofluorescence studies on unfixed ascites tumor cells were performed to assess the possibility of surface staining. Fig. 6 shows that MS2B6-stained cells had fluorescence at the cell periphery. The control IgM–stained cells had no fluorescence (not shown). However, the number of MS2B6-stained cells with such peripheral ring fluorescence was proportional to the number of nonviable cells (as judged by trypan blue exclusion) present in the three ascites specimens examined. When these experiments (including a propidium iodide counterstain to reveal nonviable cells) were repeated, almost all cells with MS2B6 ring fluorescence also had red propidium iodide nuclear staining (not shown). Ascites tumors cells that were judged viable by the lack of propidium iodide nuclear staining but that did show MS2B6 staining were rare, representing less

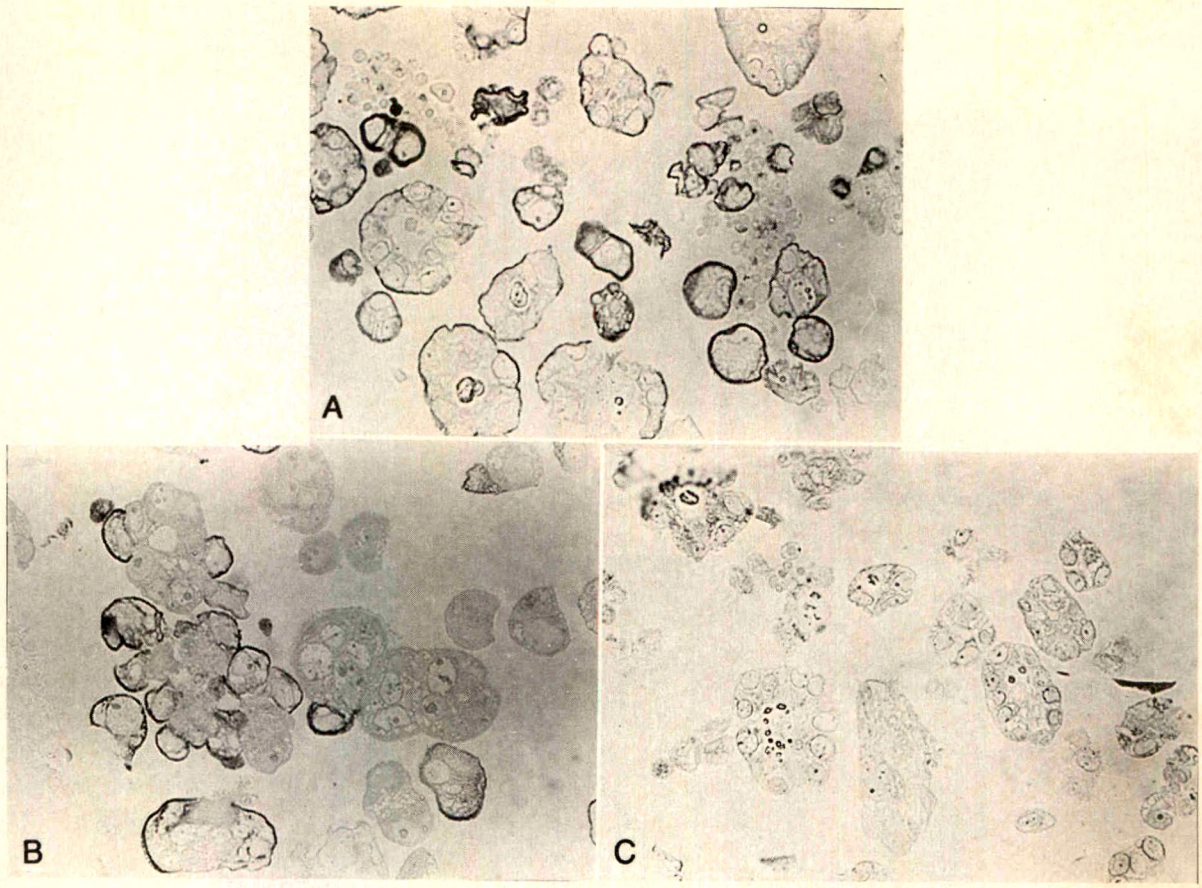

Fig. 5. Cellular localization of MS2B6 antigen. **A,** Methanol-acetone fixed ovarian cancer ascites cells (Bioton-labeled MS2B6 stain epoxy embedded; ×200); **B,** PLP-fixed ovarian cancer ascites cells (Biotin-labeled MS2B6 epoxy-embedded stain; ×200); **C,** Methanol-acetone fixed ovarian cancer ascites cells (Biotin-labeled negative control IgM epoxy-embedded stain; ×200).

than a few percent of the MS2B6 staining cells from any of the preparations studied. Although we cannot exclude the possibility that a rare viable cell does display the MS2B6 antigen on the cell surface, these results suggest that MS2B6 staining of fresh, unfixed cells is almost always restricted to damaged, nonviable cells and is not the result of surface staining of intact viable cells.

The immunoelectronmicroscopy experiments were performed to reveal the subcellular location of the bandlike staining deposits seen in the immunoperoxidase studies. Ascites tumor cells that had been methanol-acetone fixed and MS2B6 stained were chosen because in the light microscope nearly all of these cells demonstrated this ringlike deposit of DAB (Fig. 5, *A*). Fig. 7 shows electron micrographs of MS2B6-stained cells compared with control IgM-stained cells. Once again, a ringlike distribution of MS2B6 antigen is suggested. However, the layer of deposited DAB is clearly intracellular, beginning below the outer limits of the cell periphery and interdigitating with the peripheral cytoplasmic structures. Although the lipid bilayer structure of the plasma membrane is not consistently seen (presumably the result of the methanol-acetone fixation step), microvilli that serve as markers of the cell surface can be identified. The MS2B6 staining begins immediately beneath the level of these microvilli and extends into the peripheral cytoplasm in a bandlike layer.

CA 125 competition assay. MS2B6 was also tested for its ability to interfere with OC 125 in an enzyme-linked immunosorbent assay for CA 125. Although as little as 50 ng of unlabeled OC 125 inhibited the CA 125 enzyme-linked immunosorbent assay, MS2B6 in amounts up to 5 μg had no effect (data not shown). It is concluded that MS2B6 does not recognize the CA 125 epitope.

Comment

The human IgM MAb MS2B6 recognizes an antigen present in all ovarian carcinomas tested and in the majority of nonovarian adenocarcinomas. The antigen is present in trophoblastic tissue and in some fetal epi-

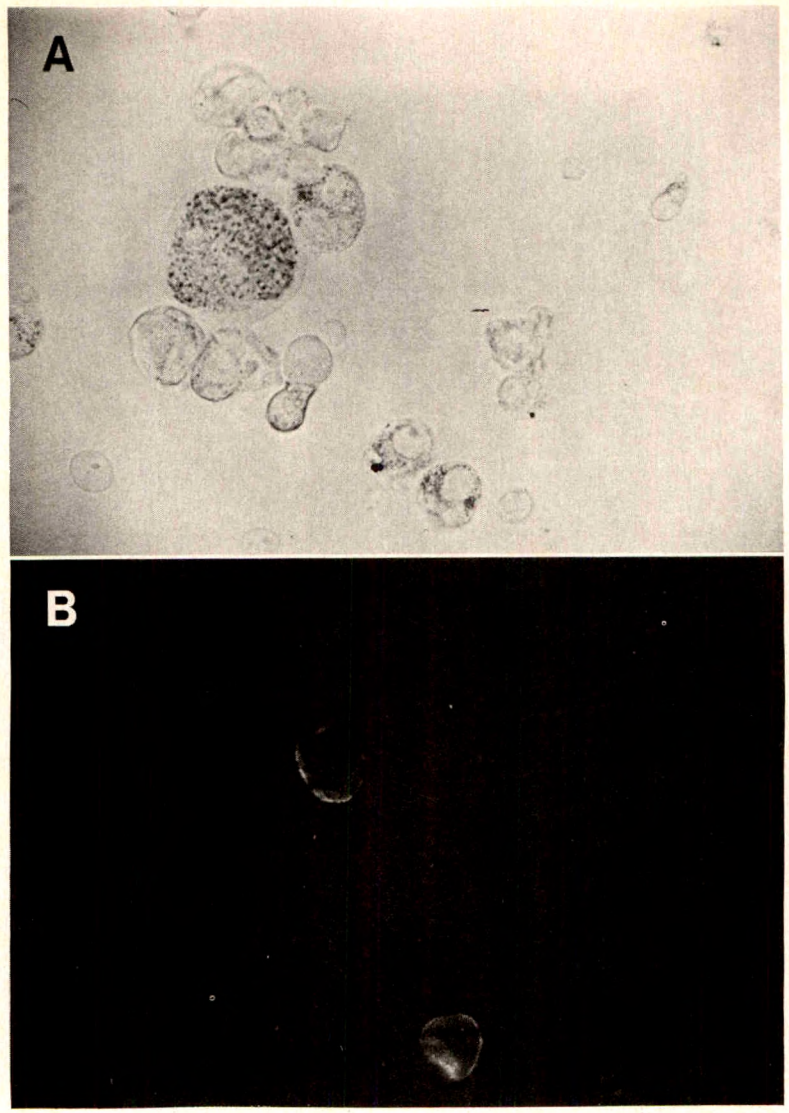

Fig. 6. MS2B6 antigen in unfixed ovarian cancer ascites tumor cells (Immunofluorescent stain). **A,** Light microscopy; **B,** Ultraviolet illumination (both same field, ×400).

thelia, but in the adult is restricted to normal, simple (nonsquamous) epithelia such as the fallopian tube, endometrium, endocervix, colon, bronchus, breast, sweat duct, and large renal ducts. The antigen was absent in normal peritoneum, stromal, or blood tissues, squamous epithelia, squamous cancers, sarcoma, melanoma, lymphoma, or malignant germ-cell tumors. The MS2B6 epitope was found to reside on polypeptides of approximately 38 and 44 kd, although some size heterogeneity was observed. A 60 kd band was observed but was not consistently present.

The MS2B6 MAb was originally detected by its ability to bind unfixed cryopreserved ovarian cancer ascites tumor cells with an immunofiltration technique.[13] This technique was selected to detect MAbs that recognized antigens on the tumor cell surface. However, the frozen-section immunoperoxidase results did not supply sufficient resolution to determine the cellular localization of MS2B6 antigen. The immunoperoxidase studies with ovarian cancer ascites tumor cells suggest that the MS2B6 antigen has a ringlike distribution near the cell periphery. However, many more cells were stained after permeabilization with methanol-acetone, suggesting that disruption of the cell membrane is required for staining by MS2B6. The initial immunofluorescence experiments also suggested a ring distribution of the MS2B6 antigen, but the propidium iodide counterstaining experiments clearly established that the MS2B6 staining pattern is rarely observed on intact viable cells, suggesting a cytoplasmic location for the MS2B6 antigen. The immunoelectronmicroscopic observations are consistent with those findings. The

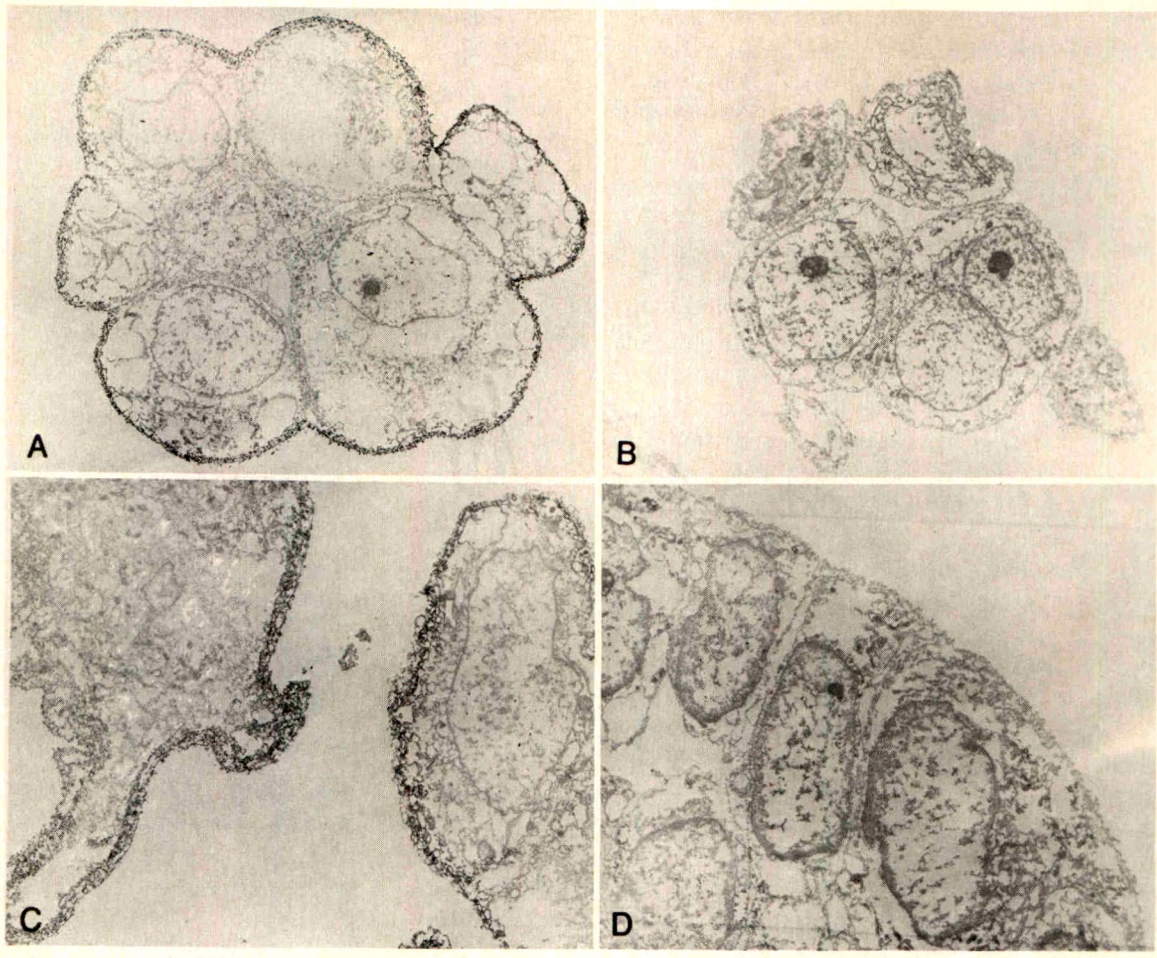

Fig. 7. Immunoelectronmicroscopy of MS2B6-stained ovarian cancer ascites cells. **A,** MS2B6-stained cells, ×1700; **B,** Control IgM-stained cells, ×1700; **C,** MS2B6-stained cells, ×2800; **D,** Control IgM stained cells, ×2800.

MS2B6 antigen is distributed in a bandlike layer of the peripheral cytoplasm in ascites tumor cells. Whether this distribution is the same for ovarian cancer tissues or normal epithelia that express the MS2B6 antigen is unknown at present.

The molecular size of the MS2B6 antigen, its tissue distribution, and its presence in the cytoplasm of ovarian cancer ascites tumor cells suggest that it could be a cytokeratin-type molecule. Human MAbs to cytokeratin-like antigens, described previously,[14, 24-26] are derived from lymphocytes of patients with adenocarcinomas of the breast, colon, and stomach. For example, human MAbs 16.88 and 28A32 were originally detected by surface staining of colon cancer cell cytospin preparations,[14] but subsequent immunofluorescence analysis with propidium iodide counterstaining suggested that the target antigens were actually cytoplasmic.[27] To our knowledge the bandlike distribution of the MS2B6 antigen in the peripheral cytoplasm of ovarian cancer ascites tumor cells has not been previously described for any of the cytokeratins, which typically display a filamentous structure throughout the entire cytoplasm of neoplastic cells.[28] The relationship between the MS2B6 antigen and the cytokeratin family is a subject of active investigation in our laboratories (Glasky MS, Yin A, Smith LH, et al., unpublished data).

The MS2B6 antigen does not appear to be identical to other cancer-associated antigens previously reported. A human IgM MAb to ovarian cancer that recognizes a predominantly nuclear antigen in ovarian cancer cells has recently been reported[29]; this pattern is quite distinct from the MS2B6 antigen distribution. A large number of ovarian cancer–associated antigens have been detected with mouse MAbs; many of these antigens possess some characteristics similar to the MS2B6 antigen, but distinct differences are recognized. For example, Miotti et al.[30] used mouse MAbs to detect ovarian cancer–associated antigens that have size characteristics similar to the MS2B6 antigen; however, unlike the MS2B6 antigen, they were not detectable after boiling in SDS. Mattes et al.[31-33] also used mouse MAbs to detect a series of ovarian cancer–associated antigens

that have size characteristics similar to the MS2B6 antigen but that are different in their behavior under reducing conditions. The competition-binding experiment presented here clearly demonstrates that MS2B6 failed to cross-react with the CA 125 epitope.

Our intention has been to use human hybridoma technology to study the human antibody response to gynecologic malignancy and to derive human MAbs of potential clinical utility. Human MAbs recognizing surface molecules on cancer cells are logical candidates for the development of imaging and therapeutic reagents and could be valuable alternatives to the more immunogenic mouse MAbs. The finding that the MS2B6 antigen is not a cell surface structure does not, however, completely eliminate the potential for clinical application of the human MAb MS2B6. In fact, monoclonal antibodies directed to intracellular antigens have been successfully used to image human tumor xenografts[34, 35] and have been shown to accumulate in damaged or necrotic tumor cells. The human MAbs 16.88 and 28A32 recognize intracellular antigens[27] and have been used successfully for localization of human colon cancer xenografts[36] and detection of metastatic disease in patients with colon cancer patients.[37] Uptake into tumor tissue of MAbs directed to intracellular antigens likely depends on the ubiquitous presence of some nonviable tumor cells. Normal healthy tissues that might express the same intracellular antigen avoid MAb uptake and thus potentially undesirable effects on imaging or therapy. We have used radioiodine-labeled MS2B6 given intraperitoneally for biodistribution studies in nude mice bearing human ovarian cancer cell line xenografts finding significant accumulation of labeled MS2B6 into intraperitoneal tumor deposits when compared with normal tissues.[38] These preliminary findings and the lack of significant toxicity or immune response to human MAbs administered to human subjects[37, 39-41] encourage further preclinical investigation of MS2B6 as an imaging or therapeutic agent.

We thank Drs. Craig Wright and Charles Birdwell for timely technical consultations and Drs. S. Avalos, N. Spirtos, S. Ballon, and W. Kinney for providing tissues and cells.

Bound volumes available to subscribers

Bound volumes of the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY are available to subscribers (only) for the 1992 issues from the Publisher, at a cost of $68.00 for domestic, $95.76 for Canada, and $91.00 for international for Vol. 166 (January-June) and Vol. 167 (July-December). Shipping charges are included. Each bound volume contains a subject and author index and all advertising is removed. Copies are shipped within 60 days after publication of the last issue in the volume. The binding is durable buckram with the JOURNAL name, volume number, and year stamped in gold on the spine. *Payment must accompany all orders.* Contact Mosby–Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318, USA; phone (800) 325-4177, ext. 4351, or (314) 453-4351.

Subscriptions must be in force to qualify. Bound volumes are not available in place of a regular JOURNAL subscription.

A randomized, placebo-controlled trial of betamethasone for the prevention of respiratory distress syndrome at 24 to 28 weeks' gestation

Thomas J. Garite, MD, Pamela J. Rumney, RNC, Gerald G. Briggs, BPharm, James A. Harding, MD, Michael P. Nageotte, MD, Craig V. Towers, MD, and Roger K. Freeman, MD

Long Beach and Orange, California

Previous randomized controlled studies of corticosteroids for the reduction of respiratory distress syndrome have failed to demonstrate benefit in very early premature gestational age groups. A randomized, double-blind, placebo-controlled clinical trial of betamethasone given to mothers with intact membranes and threatened premature delivery between 24 and 28 weeks of pregnancy was conducted. Thirty-six patients were randomized to receive betamethasone, two doses of 12 mg, 24 hours apart, and 41 received placebo. No difference was found in the overall incidence of respiratory distress syndrome between the two groups (betamethasone vs placebo 0.55 vs 0.66) or in the incidence of respiratory distress syndrome in babies delivered between 1 and 7 days after the first dose of drug (betamethasone vs placebo 0.78 vs 0.88). Nor were there any differences observed in any measure of severity of respiratory distress syndrome between the groups. The neonatal death rates were also similar (betamethasone vs placebo 0.25 vs 0.24).The only difference seen was an unexpected reduction in the betamethasone group in the incidence of grades 3 and 4 intraventricular hemorrhage (betamethasone vs placebo 1/31 vs 9/36, $p = 0.01$). Therefore this study was unable to demonstrate any beneficial effect of corticosteroids in reducing respiratory distress syndrome at <28 weeks' gestation in spite of a sample size that had an 80% likelihood of detecting a 50% reduction in the incidence of respiratory distress syndrome with $p = 0.05$, which is the minimum reduction seen in virtually all randomized trials in other gestational age groups. (AM J OBSTET GYNECOL 1992;166:646-51.)

Key words: Corticosteroids, respiratory distress syndrome, prematurity

Liggins and Howie[1] first described the administration of maternally administered corticosteroids for the acceleration of fetal pulmonary maturity in 1972. Since that time numerous randomized controlled trials have confirmed the benefit of dexamethasone or betamethasone, which, when administered to patients with threatened premature delivery, substantially decreases the risk of surfactant-deficiency respiratory distress syndrome (RDS) in the preterm newborn. Nearly all trials have confirmed this benefit but certain subgroups of patients do not seem to benefit as much or apparently at all from this therapy. One such group is those who are delivered at <28 weeks of gestation. While there may be some theoretical reasons why corticosteroids might not benefit these very premature newborns, virtually all trials of such therapy have not included sufficient numbers of patients in this gestational age range to determine benefits. Therefore we undertook this randomized controlled trial of betamethasone in patients with threatened premature delivery (between 24 and 28 weeks' gestation).

Material and methods

All patients admitted to the perinatal service of Long Beach Memorial Women's Hospital with intact membranes between 24 weeks and 27 weeks 6 days of gestation who were in premature labor or otherwise judged likely to be delivered within the ensuing week, but not within 24 hours, were eligible for inclusion in the study. All patients were managed by the same group of physicians, which included perinatal attending physicians and fellows. The study was approved by the Human Subjects Review Committee, and all patients signed informed consent forms before randomization. Estimated gestational age was determined by a reliable date of last menstrual period with ultrasonographic

*Some patients with more than one admitting diagnosis.

confirmation. When the estimated gestational age by sonogram differed by >14 days from the menstrual dates, the dates were revised to match the ultrasonography-estimated gestational age. Patients were randomized by members of the pharmacy section using a random number–generated, consecutive, sealed envelope system. Patients randomized to the study group received two doses of intramuscular Celestone (6 mg betamethasone acetate and 6 mg betamethasone phosphate) 24 hours apart. Patients randomized to the control (placebo) group received two doses of normal saline solution in the same quantity at 24-hour intervals. Both drug and placebo were prepared in the hospital pharmacy. Management was otherwise unaffected by inclusion in this study. Patients who received tocolytic therapy were given magnesium sulfate in 4 or 6 gm loading doses and maintained initially at 2 gm/hr adjusted to maintain contraction frequency at six or fewer per hour with serum levels not to exceed 7 mg/dl. Patients with ruptured membranes and clinical and/or laboratory evidence of infection, who had previously received any corticosteroids or had medical conditions contraindicating steroids, including diabetes, were excluded from this study.

Patients who had not been delivered 1 week after receiving the first dose, and who were judged still likely to be delivered in the next week, were given the same drug or placebo if the gestational age was still within the study inclusion range. Patients who had not been delivered after 28 weeks and were 1 week from their

last dose were allowed treatment with corticosteroids at the discretion of their attending physicians. Newborns were managed by attending neonatologists, and care was not altered by study participation. No neonate received surfactant therapy during the study period.

Outcome end points for the study included incidence and severity of RDS and neonatal survival. The diagnosis of RDS required clinical signs and tachypnea and retractions, supplemental oxygen therapy for at least 24 hours, and a chest x-ray film consistent with hyaline membrane disease. Secondary end points considered included maternal and neonatal infectious complications and other neonatal morbidity associated with prematurity, as well as length of neonatal hospitalization.

Statistical comparisons were made with t tests, χ^2 analysis, and Fisher's exact tests where appropriate.

Results

The study was conducted between December 1984 and May 1990. During this time 76 patients were successfully randomized, 37 to the betamethasone group and 39 to the placebo group. Of the 37 randomized to betamethasone, four were delivered elsewhere and were lost to follow-up; similarly, one patient was lost from the placebo group. Thus 33 received betamethasone and 38 placebo. All patients lost to follow-up had progressed beyond 29 weeks and would not have affected the analysis of outcome within 1 week of the last drug administered. Each group included three sets of twins. There were three stillbirths in the betamethasone group and one stillbirth in the placebo group. When twins were included and stillbirths were excluded, there were 33 neonates in the betamethasone group and 40 in the placebo group for the final neonatal analysis. Demographic and matching comparisons for the two groups are shown in Table I. As shown, there were no statistically significant differences between the two groups at the time of randomization in the interval to delivery, route of delivery, birth weight, or Apgar scores.

Of the 33 mothers in the betamethasone group, six were delivered <24 hours from the last dose of betamethasone, 13 at 2 to 7 days, and 24 after 7 days. Of the 40 randomized to placebo, eight were delivered in <24 hours, 17 between 2 and 7 days, and 12 after 1 week. Six of the betamethasone group and four of the placebo group received multiple courses of study drug or placebo (for betamethasone: two courses, four; three and four courses, one each; for placebo: two courses, one).

The incidence of maternal infections was not significantly different between the two groups. Chorioamnionitis occurred once in the betamethasone group and twice in the placebo group. Endometritis developed in 10 of 33 (30%) in the betamethasone group and five of 38 (13%) in the placebo group ($p = 0.07$). Correcting endometritis for route of delivery did not achieve statistical significance because this complication developed in seven of 16 cesarean sections in the betamethasone group and four of 20 in the placebo group ($p = 0.12$).

The incidence of RDS in the two groups is shown in Table II, including overall incidence, incidence after the exclusion of neonatal deaths within 1 hour of birth, and incidence divided by interval to delivery. As seen, in none of these analyses was a difference in the incidence of RDS observed between the two groups. In Table III the duration of intubation and the maximum inspiratory pressures, as indicators of severity of RDS, are compared between the two groups and analyzed, similarly to the incidence. Again no statistical differences in severity of RDS was noted between the betamethasone and placebo groups. There was no apparent difference between the two groups in the incidence of prolonged oxygen dependence (>30 days), either among all neonates (betamethasone vs placebo 9/33 vs 9/40) or among those with RDS (betamethasone vs placebo 9/20 vs 9/27).

Neonatal outcome is shown in Table IV, and as shown, no differences can be seen in the rates of stillbirths or neonatal deaths. Other major neonatal morbidities compared included the incidences of patent ductus arteriosus, intraventricular hemorrhage, and documented neonatal sepsis. There were no differences between the two groups in the incidence of patent ductus arteriosus, either in drug-treated or surgically treated groups or in the combined group (betamethasone vs placebo 23/33 vs 18/40) or in documented cases of neonatal-treated sepsis (betamethasone vs placebo 1 vs 3). There was, however, a substantial difference in the incidence of grades 3 and 4 intraventricular hemorrhage, with the betamethasone-treated babies having only one such case (3%) as compared with nine in the placebo group (25%), ($p = 0.012$). The incidence of grades 1 and 2 intraventricular hemorrhage was similar (betamethasone vs placebo 26% vs 25%). The difference in mean duration of neonatal hospital stay did not reach statistical significance (betamethasone vs placebo 52.8 vs 78.8 days, $t = 1.83$, $p = 0.072$).

The sample size achieved had an 80% chance of demonstrating a 50% reduction in the incidence of RDS with $p = 0.05$.

Comment

In spite of a frequent and consistent demonstration of benefit of maternally administered corticosteroids in reducing the incidence of RDS in other premature gestational age groups, the available randomized controlled trials have not shown benefit in patients treated between 24 and 28 weeks of pregnancy. There are two

Table II. Incidence of RDS

Minus 1 outlier per group	27.8 + 16 (n = 8)	27.1 + 16 (n = 9)		

All comparisons between bethamethasone and placebo showed no statistically significant differences.

possible reasons for this apparent lack of benefit. One is that this group is physiologically different, and thus the therapeutic response differs, compared with that of older gestational age groups. There are indeed reasons to expect that this may be the case. Corticosteroids are thought to promote fetal lung maturity through a number of mechanisms. The primary one is thought to be increased production and release of lung surfactant.[2, 3] Although steroid receptors are present in the type II alveolar cells, which produce surfactant as early as 12 weeks, there may be a quantitative difference in receptors as pregnancy progresses.[4] The type of surfactant produced also seems to be critical. The more mature fetus produces a disaturated phosphatidylcholine through the choline incorporation pathway. This pathway, which includes a substantial number of different enzymes thought to be affected by corticosteroids, may not be available or quantitatively as responsive in these very early gestations where other pathways for the production of surfactant may be dominant and may not be as responsive to corticosteroids.[5] Some studies suggest that steroids may work through structural changes in alveolar architecture, producing alterations in lung collagen and elastin.[6, 7] Since the early gestation lung may be more tubular and less saclike or alveolar, the lung tissue may not be as responsive to the effects of corticosteroids.

The other possible explanation is that betamethasone does lower the incidence of RDS, albeit at possibly less effective rates, but that the numbers of subjects in published study and control groups have been insufficient to demonstrate a difference. Analysis of the literature on this question is difficult, because several studies combine gestational ages or birth weights into larger groups, such as <31 weeks.[8-10] Indeed, in the review by Crowley et al.,[11] which included a meta-analysis of 12 controlled trials of corticosteroids including >3000 participants, the authors concluded that seven trials evaluating the effects of gestational age showed "an unambiguous and important reduction in the risk of respiratory morbidity among babies born at less than 31 weeks gestation." If one limits review to those specifying <29 weeks and/or ≤1000 gm or those in which data can be extracted from tables within the article, the actual number of patients in all previous individual randomized controlled trials at <29 weeks is actually quite small, the largest being that of Doran et al.[12] with 27 total patients. Even combining available randomized controlled trials gives a total of only 109 patients, all of whom showed no benefits with corticosteroid therapy.[1, 12-15] There have been several nonrandomized studies in this very premature gestational age group, where the comparison was made with control subjects who did not receive steroids for various reasons. In these studies there did appear to be less RDS in the steroid-treated patients.[16-18] Caution must prevail in interpreting these studies because the control subjects are usually not comparable. Control subjects usually re-

Table IV. Neonatal outcome

ceived β-sympathomimetic tocolytics less often than did steroid-treated patients, which may accelerate lung maturity and often included more babies with fetal distress necessitating earlier delivery, which may predispose to more cases of RDS and other nonequivalent factors.

The current study was unable to demonstrate any beneficial effect of betamethasone in reducing the incidence or severity of neonatal respiratory distress, including other associated complications such as bronchopulmonary dysplasia. Nor were there any significant trends suggesting that a larger sample size would likely have demonstrated such a benefit. While certainly not large, the total of 76 patients randomized in this study is by far the largest sample size in any single study. In fact, the sample size achieved in this study gave an 80% chance of demonstrating a 50% reduction in the incidence of RDS, which is the reduction rate in virtually all other studies in more advanced gestational ages.

Because of the strict inclusion criteria and limited gestational ages included, this study was conducted over a relatively long time period. Consequently the results of this study may be somewhat less clinically relevant than those at the time the study was originally designed. More recent studies of the prevention of RDS often include neonatal surfactant therapy. It appears preliminarily that corticosteroids may act synergistically with surfactant therapy to achieve benefit, even in the extremely premature babies included in this study.[19, 20]

A somewhat surprising reduction in the incidence of more severe grades of intraventricular hemorrhage was seen in the betamethasone-treated neonates. This would not have been a surprise if there were other differences between the two groups in the rates of RDS, severity of RDS, or an unexpected difference in Apgar scores. Such morbidities are known to increase the risk of intraventricular hemorrhage, but, other than the betamethasone itself, there are no other differences in this study between the treated and control groups that might explain the observed difference in the rate of severe intraventricular hemorrhage. However, it should be acknowledged that the only comparison between the two groups for the possible occurrence of perinatal asphyxia is by Apgar scores and other associated neonatal morbidity. Umbilical cord blood gas levels were not routinely measured at the time this study was begun; thus valid comparisons cannot be provided. Betamethasone itself may have some stabilizing effects on the fragile germinal matrix capillaries or other unknown protective mechanisms and this observed difference may be real. Previous randomized trials of corticosteroids have not shown a reduction over controls in rates of intraventricular hemorrhage. One study evaluating obstetric factors that affect rates of intraventricular hemorrhage observed a reduction in corticosteroid-treated mothers.[21] In a study evaluating the effects of antenatal vitamin K therapy on intraventricular hemorrhage, an independent beneficial effect of maternal corticosteroids was also seen.[22] In the review and meta-analysis by Crowley et al.,[11] a moderate reduction in the incidence of intraventricular hemorrhage can be seen by combining available controlled studies. Again, is this from less RDS with a secondary reduction in intraventricular hemorrhage or from some direct effect on the fetal germinal matrix? No definitive answer can be given. From the current study we are reluctant to draw any real conclusions regarding betamethasone and intraventricular hemorrhage for two reasons. First, the effect on intraventricular hemorrhage was not one of the original hypotheses, because such a beneficial effect on intraventricular hemorrhage had not been suggested when this study was started in 1984; thus the difference may be a type I error. Furthermore, the incidence of grades 3 and 4 intraventricular hemorrhage in the institution where this study was done, during this time period and at these gestational ages, ranged from 8% to 10%. Thus the 25%

incidence seen in the placebo group appears to be unusually high, possibly explained by chance alone.

The trend toward more instances of postpartum endometritis in patients receiving betamethasone is certainly a concerning one and difficult to explain. This complication has not been described in other studies of corticosteroids in patients with intact membranes. However, occult intraamniotic bacterial infection in patients in premature labor has been shown to be more common in earlier premature gestational ages than later ones.[23]

Thus a double-blind, randomized, placebo-controlled trial was conducted in patients with threatened premature delivery (before 28 weeks of gestation). In this study we were unable to demonstrate evidence of benefit in reducing the incidence or severity of RDS in spite of a sample size likely to demonstrate the magnitude of benefit seen in older gestational age groups. This study did not evaluate the utility of corticosteroids in the presence of neonatal surfactant therapy and therefore is not relevant to this more contemporary practice. The reduction of intraventricular hemorrhage seen in this study is provocative and has been suggested by a few previous investigators; thus further studies looking at this therapy for the expressed purpose of reducing intraventricular hemorrhage in these very premature babies may be warranted.

Gonadotropin and ovarian hormone dynamics in luteal phase defects

Sam E. Alexander, MD, Sezer Aksel, MD, Richard R. Yeoman, PhD, and Julianne M. Hazelton, BS
Mobile, Alabama

Blood samples were obtained during early follicular, periovulatory, and luteal phases in four women with out-of-phase endometrial biopsy specimens and four normal controls. In the study cycle, follicular development was evaluated and a late luteal phase endometrial biopsy was performed in each subject. Area under the luteal phase progesterone curve positively correlated with degree of maturity of the endometrial biopsy. Peak serum estradiol, maximum follicular diameter, and both immunoactivity and bioactivity of the preovulatory luteinizing hormone and follicle-stimulating hormone surges were similar in the luteal phase defect cycles as compared with normal cycles. Likewise luteinizing hormone bioactivity in the luteal phase of the luteal phase defect cycles was similar to that of normals. These data show that the immunoactivity and bioactivity of periovulatory and luteal phase gonadotropins may be normal in luteal phase defect cycles. (Am J Obstet Gynecol 1992;166:652-7.)

Key words: Luteal phase defect, gonadotropin, progesterone, ovulation.

Although luteal phase defect was first described 40 years ago,[1] the precise pathophysiologic characteristics of the defect remain unclear. Luteal phase defect has been suggested to be a result of many mechanisms, such as hypothalamic-pituitary dysfunction manifested by insufficient follicle-stimulating hormone (FSH) stimulation of the developing follicle,[2-5] an inadequate luteinizing hormone (LH) or FSH surge,[6-8] an attenuation of LH immunoactivity and bioactivity during the midcycle surge,[6] or a lack of proper luteal phase LH support of the corpus luteum progesterone synthesis.[9] Because the preovulatory FSH surge may play an important role in induction of LH receptors on granulosa cells in preparation for luteal phase progesterone production,[8] inadequate bioactivity of the FSH molecule during the early follicular phase or the preovulatory surge could result in poor corpus luteum response to luteal phase LH secretion. In the present study we sought to more clearly characterize the dynamics of pituitary FSH and LH secretion during the periovulatory period in patients with luteal phase defects.

Material and methods

Eight normoprolactinemic women with infertility who had a >2-day lag in a late luteal phase endometrial biopsy were included in the study. Monitoring of hypothalamic-pituitary-ovarian dynamics was started in a following menstrual cycle when a confirmatory biopsy was planned. Venous blood samples were collected daily in the early follicular phase, twice daily in the preovulatory period, and every other day during the luteal phase. Growth of the dominant follicle was monitored with a 5 MHz convex-array vaginal ultrasonographic transducer (Corometrics Medical Systems, Inc., Wallingford, Conn.) twice daily in the periovulatory period until verification of follicular rupture. This was evidenced by disappearance or flattening of the follicle with a decrease in the mean diameter. Two to five days after the LH surge, a culdocentesis was performed to confirm ovulation by determination of peritoneal fluid progesterone concentrations. Endometrial biopsy was performed 10 to 12 days after ovulation. Samples were obtained from the anterior uterine fundus with a Novak curette.

Five controls were selected from a group of women with either proven fertility or male factor infertility, normal menstrual histories, and no previous endometrial biopsies. Monitoring of the study cycle was carried out exactly as in the luteal phase defect group. None of the subjects took hormone supplements or antiinflammatory agents during the study.

Serum and peritoneal fluids were stored at −20° C until assayed. Estradiol concentration was assayed by a commercially available radioimmunoassay kit (Direct ^{125}I Estradiol, Pantex, Santa Monica, Calif.) as was serum progesterone (Coat-a-Count Progesterone, Diagnostic Products, Los Angeles). Immunoactive LH and FSH were determined by a double-antibody radioimmunoassay with LER-907 as the reference stan-

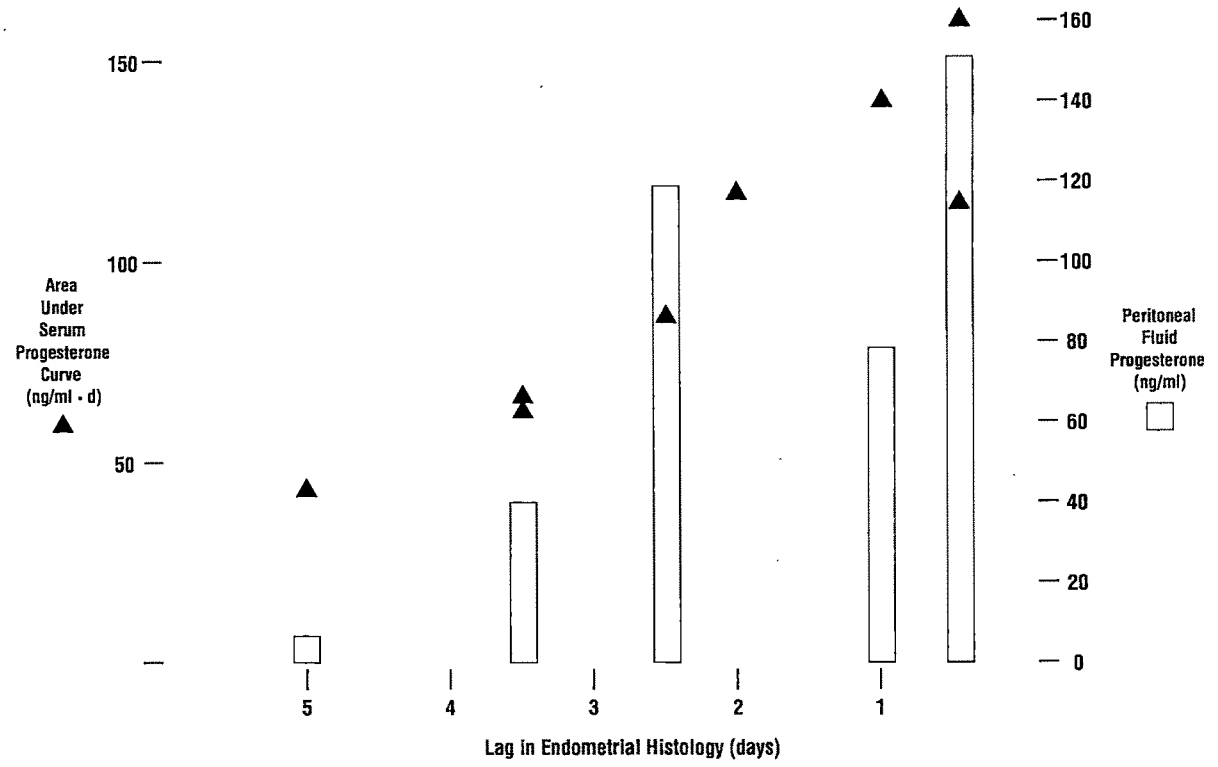

Fig. 1. Relationship of endometrial histology to peritoneal fluid progesterone concentration and area under the luteal phase progesterone curve.

dard.[10, 11] Intraassay and interassay coefficients of variation for the immunoactive LH assay were 5.3% and 11.6% and those for the immunoactive FSH assay were 5.3% and 8.8%, respectively. The sensitivity for the immunoactive LH assay was 2 ng/tube and for the immunoactive FSH assay 12 ng/tube.

Bioactive LH was determined by the mouse interstitial cell in vitro bioassay[12, 13] with LER-907 as the reference standard. The coefficients of variation were 9% and 20% within and between assay, respectively. Parallelism and potency estimates were calculated with W.E. Bridson's computer program. Bioactive FSH was measured by the rat granulosa cell aromatase in vitro bioassay with LER-907 as the reference standard.[14] This assay measures FSH-induced production of estradiol from dispersed granulosa cells obtained from diethylstilbesterol-primed rats. Each serum specimen was pretreated with polyethylene glycol to remove inhibitory substances, and duplicates were assayed in three different concentrations. The intraassay and interassay coefficients of variation were 12.5% and 14.8%, respectively. Parallelism and potency estimates were calculated with W.E. Bridson's computer program. Each endometrial biopsy was interpreted by two reproductive endocrinologists according to the criteria of Noyes et al.[15] in a blinded manner before performance of the luteal phase progesterone assays.

Areas under curves were calculated by Simpson's rule. Statistical significance was calculated by the Student t test.

Results

Repeat endometrial biopsies in five of the eight subjects in the study group were histologically in phase; therefore those subjects were excluded from further analysis. Four of the five controls had an in-phase biopsy; however, one was out of phase. Since her complete cycle was evaluated, which culminated in an out-of-phase biopsy, she was included in the luteal phase defect group. This resulted in four subjects with luteal phase defects defined as an endometrial biopsy that was >2 days out of phase, compared with a group of four controls with normal biopsies. One of the four luteal phase defect cycles had a luteinized unruptured follicle, as determined by early postovulatory peritoneal fluid progesterone concentration, which was equal to the level in the serum (Table I).

The mean area under the luteal phase progesterone curve was significantly less in the luteal phase defect group (67 ± 9 ng/ml · d) versus the normal group (132 ± 11 ng/ml · d) $p < 0.005$. This also correlated positively with peritoneal fluid progesterone levels ($p < 0.05$) and the degree of maturity of the endometrial biopsy ($p < 0.001$) (Fig. 1).

There was a trend toward lower immunoactive FSH levels on cycle days 1 to 3 in the luteal phase defect

Table II. Peak gonadotropin and estradiol values and follicular diameters in luteal phase defect and control subjects during the preovulatory gonadotropin surge and luteal phase length (mean ± SEM)

	Control (n = 4)	*Luteal phase defect (n = 4)*
Peak immunoactive LH (ng/ml)	319 ± 172	243 ± 74
Peak bioactive LH (ng/ml)	2446 ± 1035	2348 ± 157
Peak immunoactive FSH (ng/ml)	788 ± 102	776 ± 63
Peak bioactive FSH (ng/ml)	814 ± 112	766 ± 63
Serum progesterone at LH surge (ng/ml)	0.61 ± 0.13	0.78 ± 0.13
Peak serum estradiol (pg/ml)	324 ± 42	273 ± 37
Maximum follicular diameter (mm)	21 ± 2.8	17 ± 0.3
Luteal phase length (days)	14 ± 0	11.3 ± 1.5

group than in the normal subjects, but this did not reach statistical significance (307 ± 12 ng/ml vs 472 ± 140 ng/ml). Early follicular phase bioactive FSH levels were not assayed. Immunoactive LH levels were similar during the same time period (64 ± 0.5 ng/ml vs 50 ± 7.6 ng/ml). Comparison of gonadotropin levels during the preovulatory surge in the two groups showed no difference in peak immunoactive LH, bioactive LH, immunoactive FSH, or bioactive FSH (Table II). At the onset of the surge, progesterone levels were similar in the two groups, as were peak estradiol levels and maximum follicular diameter (Table II). Likewise, there were no differences in areas under the immunoactive or bioactive LH or immunoactive or bioactive FSH curves between the two groups during the surge (Fig. 2). Although the luteal phase of the subject with luteinized unruptured follicle had a 9-day luteal phase, whereas the other subjects with luteal phase defect had 12-day luteal phases, midcycle hormonal parameters were similar (Table III).

Although the subjects with normal luteal phase endometrial biopsies had similar luteal phase immunoactive and bioactive LH levels, there was marked individual variation noted among three of the subjects with luteal phase defect, resulting in no statistically significant differences between those three subjects and a group of three controls (Fig. 3).

Comment

Soules et al.[6] have shown luteal phase defects to be associated with abnormally low immunoactive LH and bioactive LH levels at the time of the midcycle surge and low bioactive LH levels in the luteal phase. This suggests that luteal phase defect is a consequence of poor gonadotropin stimulation of a corpus luteum that may otherwise have normal steroidogenic potential. Because granulosa cells develop the capacity to synthesize and secrete progesterone at the time of the LH surge but do not secrete it in response to luteal phase LH pulses,[16] a faulty LH surge could lead to deficient progesterone production by luteinized granulosa cells. Additionally, low luteal phase bioactive LH levels would be expected to result in low progesterone production by the LH-responsive luteinized theca cells.

Alternatively, others have shown that this situation may not be present in some women with luteal phase defect who develop luteal phase inadequacy in spite of normal midcycle[17] and luteal phase[5] gonadotropin secretion. This may be due to poor response at the level of the corpus luteum or inability of the endometrium

to respond to normal levels of progesterone because of a receptor defect. In spite of the small number of subjects in our study, by performing a thorough evaluation of midcycle and luteal-phase gonadotropin immunoreactivity and bioactivity by increasing the frequency of sampling, we were able to demonstrate gonadotropin values, in subjects with luteal phase defects, that did not deviate significantly from normal subjects. In fact, our data suggest heterogeneity in the etiology of luteal phase defect, suggesting that its origin may not necessarily be found at the level of the hypothalamic-pituitary axis in each case. This heterogeneity may account for the discrepancy between our findings and those of Soules et al.[6]

The finding of a correlation between luteal phase progesterone levels and endometrial secretory maturation demonstrated that the endometrium was capable of responding to progesterone in a quantitative fashion in the subjects of this study. This implies normal progesterone receptor function and suggests that the mechanism responsible for luteal phase defects in these subjects was not located at the level of the endometrium. The defect would seem to be localized to the ovary after the midfollicular phase, more specifically to the corpus luteum as women with luteal phase defects had normal periovulatory and luteal phase bioactive and immunoactive LH levels when sampled twice daily, although more frequent sampling would be helpful to confirm these findings because of the pulsatile nature of LH release throughout the menstrual cycle. The presence of a luteinized, unruptured follicle in one luteal phase defect cycle demonstrates that the two conditions can coexist but fails to demonstrate a causative relationship.

There was a trend toward lower early follicular phase immunoactive FSH values in the subjects with luteal

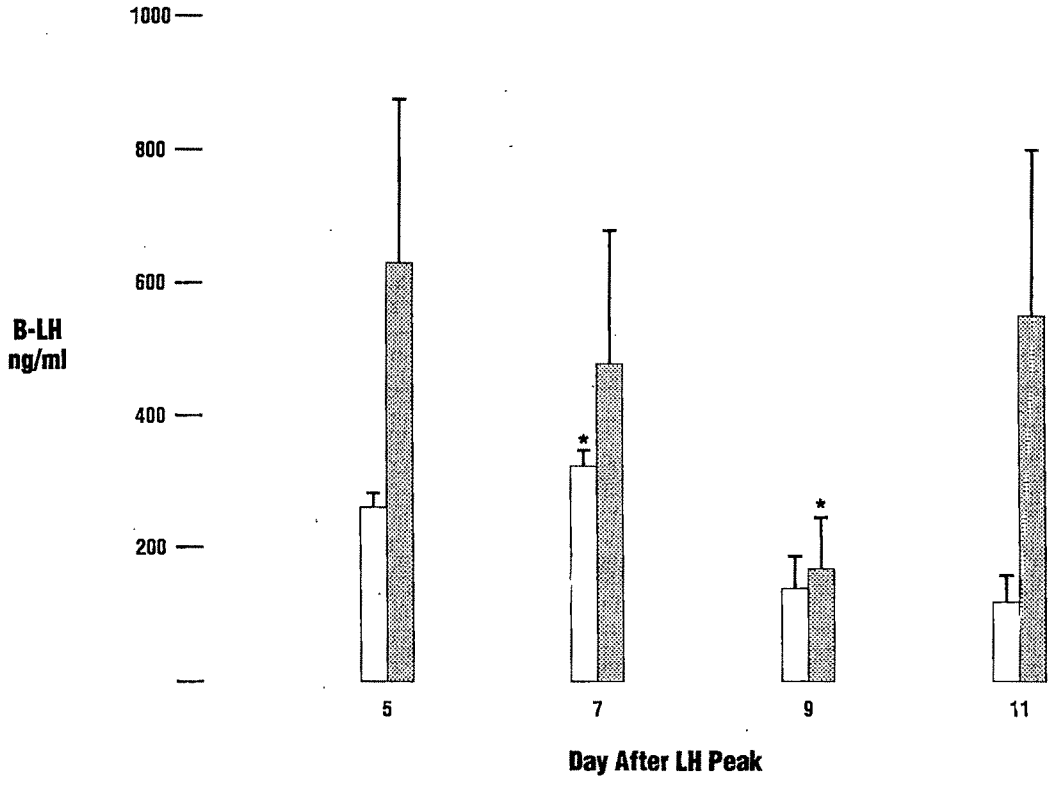

Fig. 3. Luteal phase LH values (mean ± SEM).

phase defect, but this did not reach statistical significance. Evaluation of a larger group of subjects with shorter sampling intervals would be more likely to identify any real difference. However, because of its relatively long half-life, the variation in serum immunoactive FSH concentration is less marked than that of immunoactive LH.[18] Follicular development, as measured by mean maximum follicular development and peak estradiol levels, was similar in the two groups.

The midcycle FSH surge may augment luteal phase corpus luteum responsiveness to LH by inducing its synthesis receptors on granulosa cells. Because luteinized granulosa cells synthesize and secrete progesterone during the first 10 days of the luteal phase,[16] luteal phase inadequacy in the face of normal luteal phase LH levels could be due to a poor midcycle FSH surge.[8] Our data revealed no difference in peak bioactive or immunoactive FSH levels between the normal and luteal phase defect groups, however. Likewise there was no difference in the area under the bioactive or immunoactive FSH curves between the two groups.

As previously observed and reported,[6, 8, 9] luteal-phase progesterone levels, calculated as the area under the curve, were lower in the luteal phase defect subjects in our study. These subjects also demonstrated lower progesterone concentrations in the postovulatory peritoneal fluid, suggesting that suboptimal ovarian progesterone secretion may be manifested as early as the periovulatory period. To our knowledge this is the first report of low peritoneal fluid progesterone concentrations in luteal phase defect cycles.

These data together with that from other studies[2-9, 19, 20] show that luteal phase defect may result from several conditions, including dysfunctional gonadotropin secretion, poor ovarian response to normal gonadotropin secretion, or inadequate endometrial secretory maturation in spite of normal ovarian progesterone secretion. An attempt to attribute the cause of all cases of luteal phase defect to only one of these mechanisms may be erroneous. Further investigation into early follicular phase and midcycle gonadotropin secretion and peritoneal fluid progesterone accumulation in normal and luteal phase defect cycles may enhance our understanding of this controversial condition.

Serial thoracic versus abdominal circumference ratios for the prediction of pulmonary hypoplasia in premature rupture of the membranes remote from term

M. D'Alton, MD,[a] B. Mercer, MD,[b] E. Riddick, MD,[c] and D. Dudley, MD[c]

Boston, Massachusetts, Memphis, Tennessee, and Ottawa, Ontario, Canada

OBJECTIVES: The purpose of this study was to evaluate the fetal thoracic versus abdominal circumference ratio in the prediction of pulmonary hypoplasia after preterm premature rupture of the membranes.

STUDY DESIGN: A standard curve of thoracic versus abdominal circumference ratio versus gestational age was derived from 120 uncomplicated pregnancies. Thoracic versus abdominal circumference ratio and amniotic fluid estimations were obtained serially in 16 women with premature rupture of the membranes at <26 weeks' gestation.

RESULTS: An abnormal thoracic versus abdominal circumference ratio predicted lethal pulmonary hypoplasia in six infants. A progressive decline in thoracic versus abdominal circumference ratio was identified in all of these patients. Six of eight women with persistent oligohydramnios had abnormal thoracic versus abdominal circumference ratios and lethal pulmonary hypoplasia. Two surviving infants had restriction deformities and pulmonary complications.

CONCLUSIONS: In the setting of premature rupture of the fetal membranes at <26 weeks, serial thoracic versus abdominal circumference ratio measurement is a reliable predictor of pulmonary hypoplasia. Persistent oligohydramnios is ominous because of the risk of restriction deformities and pulmonary complications in the survivors. (Am J Obstet Gynecol 1992;166:658-63.)

Key words: Pulmonary hypoplasia, prenatal diagnosis, premature rupture of fetal membranes

Pregnancy complicated by premature rupture of the fetal membranes before 26 weeks' gestation carries a significant risk of fetal and neonatal morbidity and mortality. Taylor and Garite[1] reported on the outcome of 53 cases of premature rupture of fetal membranes before fetal viability after expectant management. Beydouin and Yasin[2] identified a perinatal survival rate of 22% in infants of 70 women with premature rupture of fetal membranes before 28 weeks' gestation, 29.4% of 17 surviving infants were physically and developmentally normal at 6 months of age. Moretti and Sibai[3] demonstrated a 68% perinatal mortality, when premature rupture of fetal membranes occurred before 26 weeks' gestation, and an 87% mortality, when premature rupture of fetal membranes occurred before 23 weeks' gestation. In that study, 33% of the surviving infants had developmental abnormalities.

6/1/31809

Retrospective analysis of 50 patients treated at the University of Ottawa with premature rupture of fetal membranes that occurred between 16 and 26 weeks indicated that prolonged maternal hospitalization was common, the mean stay was 29.2 days. Chorioamnionitis developed in 42% of patients. Thirty-six percent of live-born infants died of pulmonary complications; five of these (15.2%) died of pulmonary hypoplasia. Only 16 of 55 infants, including 5 sets of twins (29.1%) survived, three of whom demonstrated serious neurologic handicaps at 1 year of age as a result of intraventricular hemorrhage.

Pulmonary hypoplasia is a major contributor to neonatal mortality in infants of women experiencing premature rupture of fetal membranes before 26 weeks' gestation. Many of these women pursue expectant management. Several clinical tests have been suggested to predict pulmonary hypoplasia, however, findings have not been consistent.

The purpose of this study was to create a standard curve for the thoracic circumference versus abdominal circumference ratio in a middle-class Caucasian population, to determine the value of serial thoracic versus abdominal circumference ratio measurements in the prediction of pulmonary hypoplasia and neonatal death in infants whose mothers experience premature

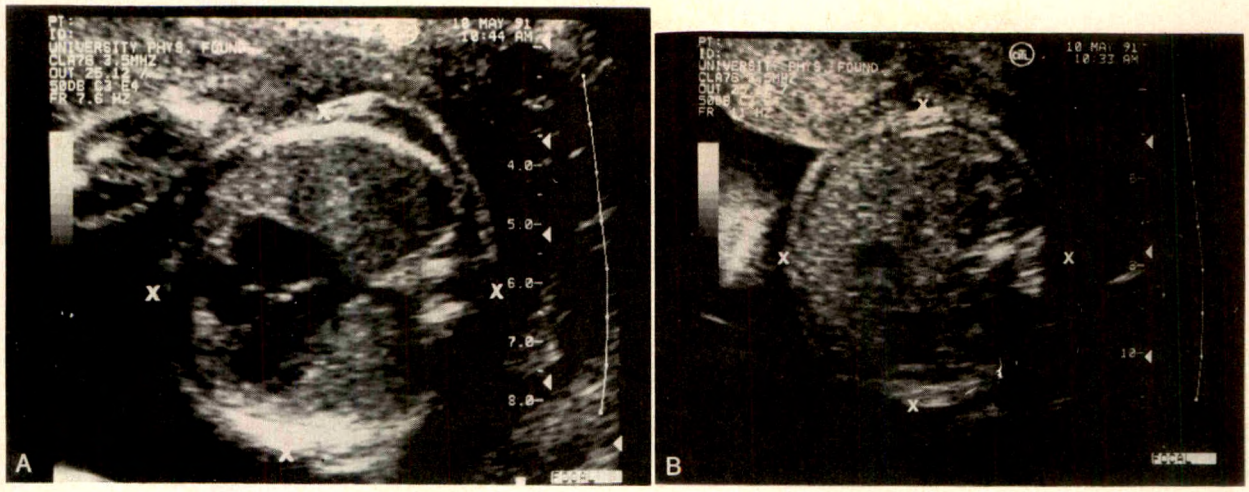

Fig. 1. A, Cross-sectional sonogram of fetal chest at level of four-chamber view of heart. **B,** Cross-sectional sonogram of fetal abdomen at level of bifurcation of umbilical vein.

rupture of fetal membranes before 26 weeks' gestation, and to determine the value of qualitative amniotic fluid volume assessment in the prediction of perinatal outcome in this population.

Material and methods

One hundred twenty women with secure dates based on menstrual history and/or early ultrasonography and appropriate growth for gestational age underwent ultrasonographic measurements of the fetal thoracic and abdominal circumferences. Measurements of the thoracic circumference were performed in the transverse plane of the fetus at the level of the four-chamber view of the heart (Fig. 1, *A*). The fetal abdominal circumference was measured in the transverse plane at the level of the insertion of the umbilical vein (Fig. 1, *B*). The thoracic versus abdominal circumference ratio was obtained for each fetus, and a scatter plot of thoracic versus abdominal circumference ratio versus gestational age was created. Simple linear regression was performed with the method of least squares. Confidence intervals that were based on ±2 SDs were applied between 14 and 40 weeks' gestation (Figs. 2, 3).

Between October 1, 1984 and December 31, 1987, 17 patients with premature rupture of fetal membranes that occurred before 26 weeks' gestation were referred to the high-risk unit at the Ottawa Civic Hospital for evaluation and management. Patients who had confirmed membrane rupture were initially evaluated 1 week after hospitalization to treat premature rupture of fetal membranes. Ultrasonographic assessment was performed to rule out associated fetal anomalies (particularly urogenital anomalies that might lead to persistent oligohydramnios and pulmonary hypoplasia). Patients were restricted to bed rest at home from the time of diagnosis to that of fetal viability and were then admitted to the hospital from 26 weeks' gestation until delivery. Fetal surveillance consisted of daily fetal movement charting, biweekly nonstress testing, and biweekly biophysical profile scoring performed weekly from 26 weeks' gestation.

Serial ultrasonographic measurements that included obtaining the thoracic versus abdominal circumference ratios were performed at 1- to 2-week intervals and were correlated to fetal outcome and autopsy data. Subjective assessment of amniotic fluid volume was performed at each scan. Amniotic fluid volume was considered normal if there was one pocket that measured at least 3 cm in the vertical axis. Neonatal outcome was reviewed with respect to perinatal pulmonary morbidity and mortality. Pulmonary hypoplasia was defined as a lung weight/body weight ratio of 0.012 or less.[4]

Results

Sixteen of 17 women studied suffered membrane rupture immediately before hospitalization. One woman who was first assessed at 23 weeks' gestation (thoracic versus abdominal circumference ratio 0.71) had prolonged membrane rupture before admission. All patients had had ultrasonography within 2 weeks before delivery.

After counseling, 16 of 17 patients elected to continue their pregnancies. Thirteen infants were delivered after 26 weeks' gestation, 8 of these 13 (62%) survived. None of the three infants who were delivered before 26 weeks survived. The mean time from premature rupture of fetal membranes to delivery was 61.8 days, the range was 31 to 152 days. The final thoracic versus abdominal circumference ratio for each infant before delivery was compared to the standard curve for our population (Fig. 2). The six infants with pulmonary hypoplasia predicted by an abnormally low tho-

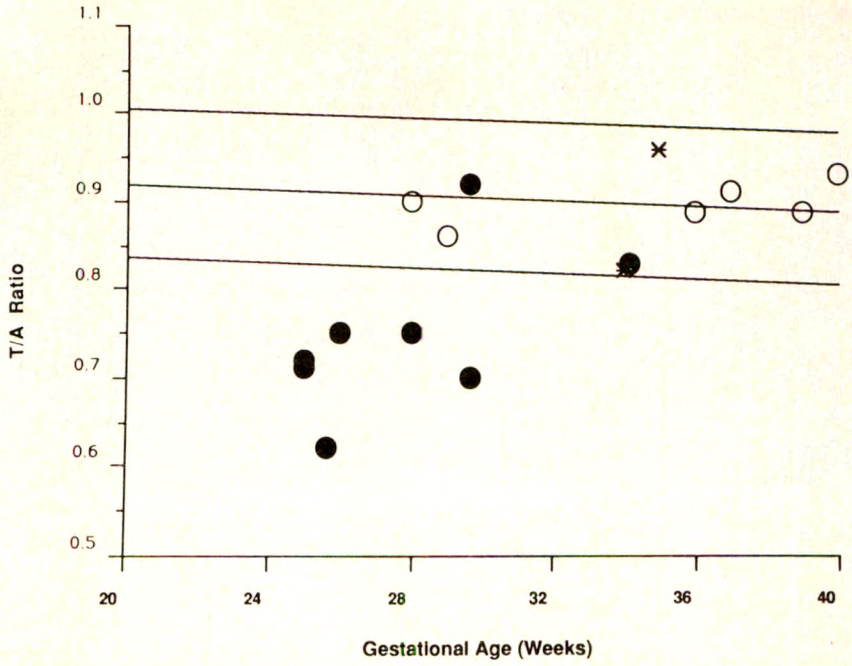

Fig. 2. Final thoracic versus abdominal circumference ratio versus gestational age before delivery for survivors *(open circles)*, survivors with restriction deformities and pulmonary complications *(asterisks)*, and neonatal deaths *(closed circles)*. *Lines* demarcate predicted values ± 2 SDs that are based on 120 women with uncomplicated pregnancies.

racic versus abdominal circumference ratio died from pulmonary hypoplasia determined by autopsy.

Two infants with normal thoracic versus abdominal circumference ratios died early in the neonatal period. The mother of the first experienced premature rupture of fetal membranes at 16.4 weeks' gestation and was delivered of her infant at 29 weeks' gestation. The thoracic versus abdominal circumference ratio on the day of her delivery was 0.92, but the infant died within 20 minutes of birth after failure of ventilation in spite of high ventilation pressures. Autopsy of this infant revealed normal lung weights with the absence of alveolar development.

The second infant, who was delivered at 34 weeks' gestation, died of pulmonary dysplasia after the mother had experienced premature rupture of fetal membranes at 23 weeks' gestation. The thoracic versus abdominal circumference ratio 4 days before delivery was 0.83. This infant died within 5 minutes of birth as a result of failure of ventilation. Lung weights were at the fifth percentile for gestational age. Lung microscopy revealed a typical pattern of pulmonary dysplasia.

Thus the thoracic versus abdominal circumference ratio had a 75% sensitivity and 100% specificity for the prediction of neonatal death from pulmonary disease. The positive and negative predictive values were 100% and 80%, respectively. The sensitivity of the thoracic versus abdominal circumference ratio in the prediction of pulmonary hypoplasia was 100%.

Serial ultrasonographic evaluation revealed appropriate growth of the abdominal circumference in all cases. Thoracic versus abdominal circumference ratios of survivors did not vary significantly among individual assessments and paralleled the predictive curve (Fig. 3, *A*). Seven of eight infants who died from pulmonary disease were followed-up within 1 week of premature rupture of fetal membranes. The eighth woman studied had ruptured membranes at 15 weeks' gestation and was first assessed at 22 weeks' gestation. All seven infants scanned within 1 week of premature rupture of fetal membranes had normal thoracic versus abdominal circumference ratios at the time of first assessment. Thoracic versus abdominal circumference ratios subsequently declined into the abnormal range in five of these fetuses (Fig. 3, *B*).

Eight women demonstrated persistent oligohydramnios to the time of delivery; six of their fetuses had abnormal thoracic versus abdominal circumference ratios. All six of these infants died as a result of pulmonary hypoplasia. Two fetuses whose mothers experienced persistent oligohydramnios had normal thoracic versus abdominal circumference ratios before delivery, and one whose mother had premature rupture of fetal membranes at 17 weeks and delivery of her infant at 35 weeks developed a pneumothorax and demonstrated significant restriction deformities of the lower extremities that required orthopedic splinting. This infant was normal at the 15-month follow-up. The second

infant whose mother had premature rupture of fetal membranes at 23 weeks' gestation and delivery at 34 weeks' gestation as a result of abruptio placentae suffered pneumomediastinum and demonstrated prominent skin folding of the neck that was indicative of intrauterine crowding.

Fetal breathing was seen at each examination in five of the six infants who died of pulmonary hypoplasia. Although fetal breathing movements were not routinely assessed in labor, regular fetal breathing was identified shortly before delivery in both infants who died of pulmonary dysplasia.

Comment

Premature rupture of fetal membranes before 26 weeks' gestation carries the risk of significant maternal morbidity; chorioamnionitis developed in 42% of reviewed mothers at our institution. With a mean latency from premature rupture of fetal membranes to delivery of 61.8 days (range, 31 to 152 days), prolonged maternal hospitalization is common. A decrease in the fetal thoracic circumference has been suggested as a predictor of subsequent neonatal pulmonary hypoplasia subsequent to oligohydramnios.[5, 6]

Callan et al.[7] reported a case of premature rupture of fetal membranes in an infant with pulmonary hypoplasia and a decreased thoracic versus abdominal circumference ratio. They suggested that the decrease in thoracic versus abdominal circumference ratio might be helpful in the antenatal prediction of pulmonary hypoplasia. A subsequent report from this group studied the use of the fetal thoracic versus abdominal circumference ratio in patients with premature rupture of fetal membranes before 28 weeks' gestation and in patients with oligohydramnios and intact membranes.[8] In a comparison of a variety of fetal measurements and ratios in fetuses at risk for pulmonary hypoplasia, Vintzileos et al.[9] found that ultrasonographic assessment was relatively insensitive (33% to 85%) and nonspecific (57% to 85%).

The fetal thoracic versus abdominal circumference ratio remains virtually constant throughout gestation.[9, 10] Chitkara et al.[10] found a mean thoracic versus abdominal circumference ratio of 0.89 with a lower limit of normal of 0.77 (mean, 2 SDs). Vintzileos et al.[9] demonstrated a lower mean thoracic versus abdominal circumference ratio of 0.85. In that study, a thoracic versus abdominal circumference ratio <0.75 was considered normal. Our cross-sectional study confirms these findings, lower limits of normal were 0.83 at 15 weeks and 0.80 at term.

In our study, only patients with premature rupture of fetal membranes before 26 weeks' gestation and without other identifiable causes of oligohydramnios were included. All six patients with pulmonary hypoplasia predicted by abnormal thoracic versus abdominal circumference ratios died of this disease. Two patients with normal thoracic versus abdominal circumference ratios died of pulmonary dysplasia. In both these cases, lung weights were within the normal range, which suggests that prenatal evaluation by thoracic versus abdominal circumference ratio could not have predicted death in these infants. This finding demonstrates that lung size and weight in the normal range do not necessarily predict normal lung function. A normal thoracic versus abdominal circumference ratio in the patient with premature rupture of fetal membranes before 26 weeks can not guarantee a good clinical outcome.

Nimrod et al.[5] have reported that thoracic circumference that is less than the fifth predicted percentile is a predictor of pulmonary hypoplasia. In our patient group, one case of pulmonary hypoplasia predicted accurately with thoracic versus abdominal circumference ratios would have been missed if the thoracic circumference estimation had been used alone, because the infant's overall size was above average. As demonstrated by Vintzileos et al.[9] the use of the abdominal circumference as an internal "control" could help to correct for variation in fetal size at a given gestational age.

The final objective of this study was to assess the use of qualitative assessment of amniotic fluid volume in the prediction of perinatal outcome. All six infants who died of pulmonary hypoplasia had both abnormal thoracic versus abdominal circumference ratios, and their mothers had persistent oligohydramnios. Two infants who died of pulmonary dysplasia and who had normal lung weights had mothers with normal amniotic fluid volumes. The mothers of two surviving infants had persistent oligohydramnios. One of these infants had significant restriction deformities of the extremities, and the other had prominent skin folds of the neck that suggested intrauterine crowding. Both these infants had respiratory complications after delivery: one suffered pneumothorax and the other developed a pneumomediastinum. Perlman et al.[11] have suggested that after 2 weeks of premature rupture of fetal membranes with persistent oligohydramnios, pregnancy should be discontinued because of the high risk of pulmonary hypoplasia. We have found that a poor perinatal outcome is associated with persistent oligohydramnios in women who experience premature rupture of fetal membranes before 26 weeks' gestation. However, two of eight infants (25%) survived and are normal at follow-up.

Ultrasonographic assessment of premature rupture of fetal membranes may be technically difficult as a result of the loss of the fluid-surface interface, juxtapositioning of soft tissue structures, and distortion of

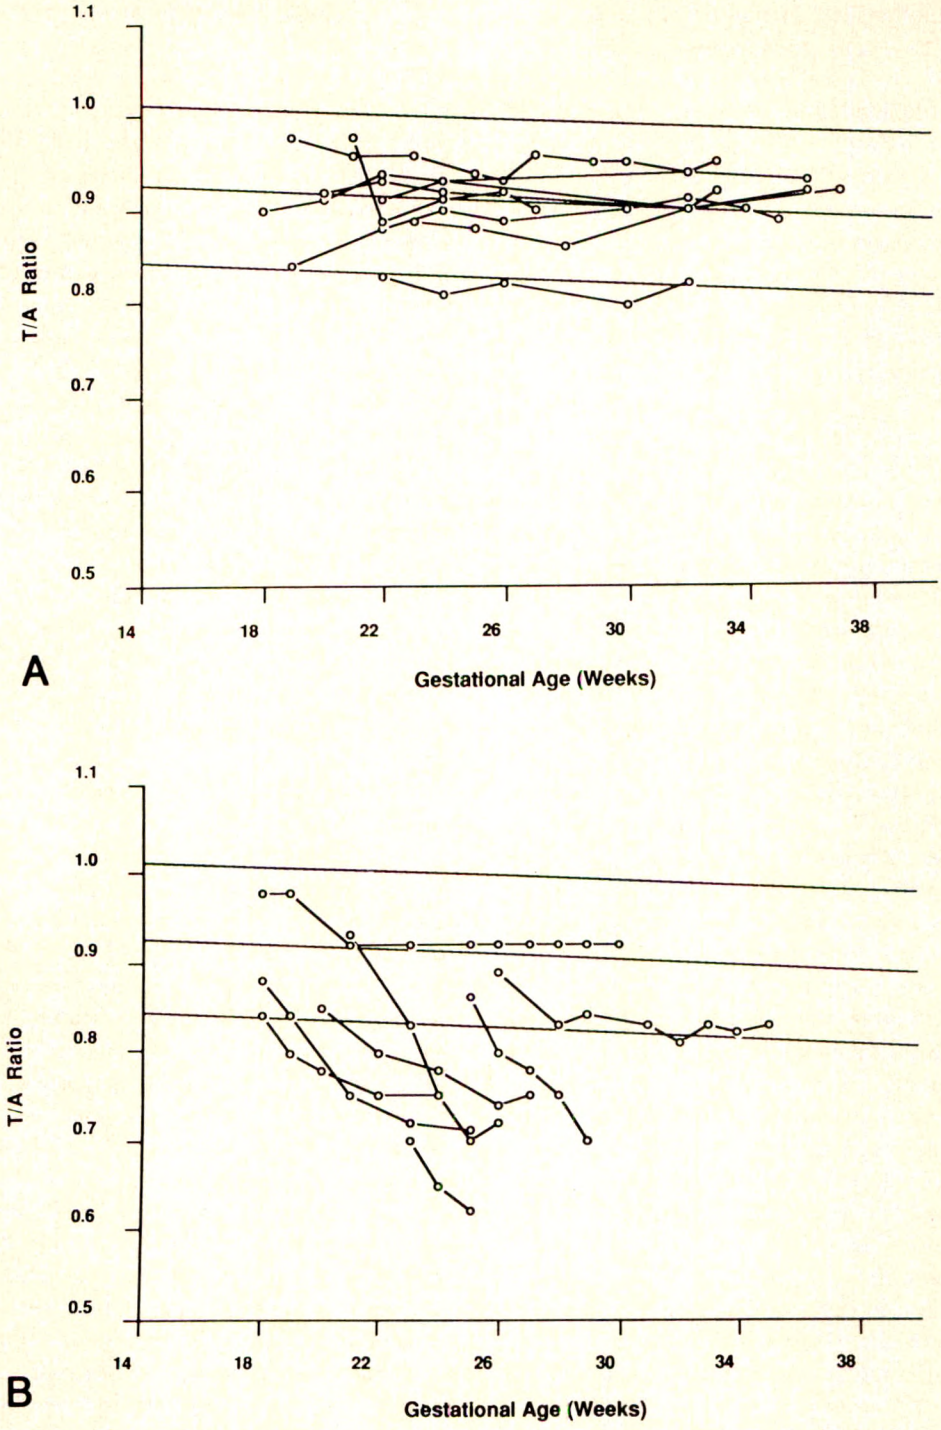

Fig. 3. A, Serial thoracic versus abdominal circumference ratios versus gestational age for surviving infants. **B,** Serial thoracic versus abdominal circumference ratios versus gestational age for nonsurviving infants.

the abdominal circumference. It might be suggested that the chest circumference should be compared with other more consistent internal fetal markers, such as the head circumference or femur length. We have found the thoracic versus abdominal circumference ratio to be reliable and without significant technical difficulty. Any ultrasonographic measurement technique requires the passage of time to identify thoracic growth failure and thus is less sensitive in patients with a short latency. We would expect approximately 5% of the normal population to have measurements smaller than the lower confidence interval for the population (2 SDs below the mean). Serial assessment may be helpful, because these patients should maintain their position on

the standard curve but those infants destined to develop pulmonary hypoplasia demonstrate progressive growth failure (Figs. 3, *A* and 3, *B*). Finally, it is important that patients be compared to a standard curve appropriate to their population. Ideally, normal curves would be constructed at each institution.

The literature contains conflicting results about fetal breathing movements as predictors of lethal pulmonary hypoplasia. In 1987, Blott et al.[12] stated that fetal breathing movements were predictive of a favorable outcome in oligohydramnios. Subsequently, Kilbride et al.[13] and Moessinger et al.[14] disputed this finding. In our evaluation, fetal breathing was consistently identified, regardless of thoracic versus abdominal circumference ratio, in seven of eight infants who subsequently died of pulmonary disease. Thus the presence of fetal breathing movements before labor does not predict good neonatal pulmonary function.

Conclusion

An abnormal thoracic versus abdominal circumference ratio is a reliable predictor of pulmonary hypoplasia. Patients with normal thoracic versus abdominal circumference ratios should be informed that there is still a risk of neonatal death from pulmonary complications. Reaccumulation of amniotic fluid indicates a more favorable prognosis. Patients with persistent oligohydramnios and fetuses with a normal thoracic versus abdominal circumference ratio should be advised of the risk of fetal restriction deformities and the potential for postpartum pulmonary complications. We recommend the use of serial thoracic versus abdominal circumference ratio testing with amniotic fluid assessment in the ongoing clinical management of patients who experience premature rupture of fetal membranes before 26 weeks' gestation.

Triplet pregnancy involving complete hydatidiform mole and two fetuses: Genetic analysis by deoxyribonucleic acid fingerprint

Chihiro Azuma, MD, DMSci,[a] Fumitaka Saji, MD, DMSci,[b] Masahiko Takemura, MD,[b] Kazutomo Ohashi, MD,[b] Tadashi Kimura, MD,[b] Akira Miyake, MD, DMSci,[b] Tetsu Takagi, MD, DMSci,[b] and Osamu Tanizawa, MD, DMSci[b]

Osaka, Japan

A case of a triplet pregnancy involving a dizygous twin pregnancy and a complete hydatidiform mole after therapy with human menopausal gonadotropin and human chorionic gonadotropin is reported. Two female fetuses, two placentas in one mass with two amnions and two chorions, and a tumor mass with a grapelike appearance were spontaneously delivered at 19 weeks of gestation. The deoxyribonucleic acid fingerprints of the two placentas and tumor tissue were compared with those of the parents. The fingerprints of the placentas showed patterns different from each other; however, all their polymorphic fragments could be traced back to either the father or mother. All polymorphic fragments of the tumor tissue were inherited only from the father (androgenesis). These results indicated that this triplet pregnancy involved a dizygous twin pregnancy and a complete hydatidiform mole. (AM J OBSTET GYNECOL 1992;166:664-7.)

Key words: Triplet pregnancy, human menopausal gonadotropin, human chorionic gonadotropin, hydatidiform mole, deoxyribonucleic acid fingerprint

Complete hydatidiform mole is the most common trophoblastic tumor deriving from the fertilization of an anuclear empty ovum by a haploid sperm that duplicates its complementary chromosomes or by two sperms. Although reports vary, it is a well-known fact that the tumor shows specific geographic distribution in its incidence. Recent reports have indicated that the incidence of complete mole is 1 per 1200 pregnancies in the United States, 1 per 500 in Japan, and 1 per 100 in Indonesia.[1-3] However, the incidence of complete hydatidiform mole with a coexisting fetus is not so frequent, being estimated to be 1 per 22,000 to 100,000 pregnancies.[4] There have been only two reports of complete hydatidiform mole in triplet pregnancy with two normal fetuses and placentas.[5, 6] Both cases were pregnancies occurring after ovulation-inducing therapy. Recently, we experienced a case of spontaneous abortion of two living female fetuses and a tumor mass with a grapelike appearance after ovulation-inducing therapy by human menopausal gonadotropin (hMG) and human chorionic gonadotropin (hCG). To investigate the zygosity of the two fetuses and the pathogenesis of the tumor, we introduced the newly developed method of deoxyribonucleic acid (DNA) fingerprint analysis, which has been reported to be a very useful tool for zygosity determination in multiple pregnancy[7] and the study of pathogenesis of trophoblastic tumors.[8, 9] Comparisons of DNA fingerprints among the fetuses, tumor, and the parents revealed that this case was a triplet pregnancy involving a dizygotic twin pregnancy and a complete androgenic hydatidiform mole. Ovulation induction therapy resulting in the production of immature ova could be one of the risk factors for hydatidiform mole.

Case report

The patient was a 24-year-old woman, gravida 0, para 0. She had received hormonal therapy for anovulation. The pregnancy described here was achieved by hMG and hCG therapy. An ultrasonographic examination at 7 weeks of gestation revealed two living fetuses and two placentas. However, at that time the multiple cystic echo typical of a hydatidiform mole was not identified. At 15 weeks of pregnancy the patient had uterine cramps with a little genital bleeding. She was diagnosed to have threatened abortion and thus was hospitalized. During hospitalization, no clinical symptoms of preeclampsia or hyperthyroidism were recognized, and ultrasonographic examination revealed two living fetuses but did not detect any multiple cystic echo. Twenty-five days later, two female infants, two placentas and a grapelike tumor were delivered. The first fetus was female, weighing 235 gm, and the second fetus was female,

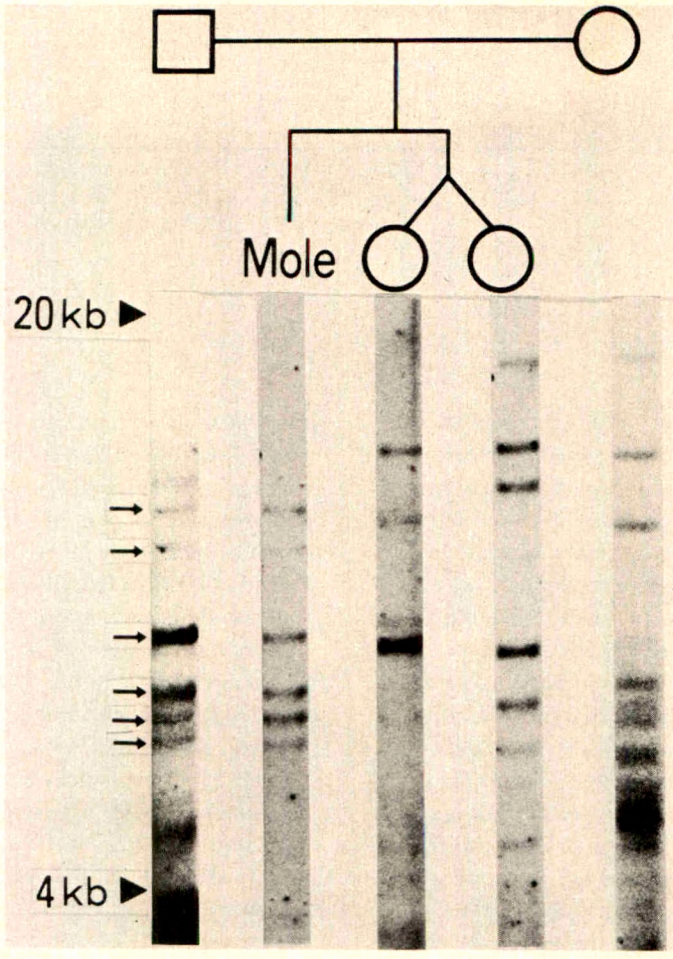

Fig. 1. DNA fingerprints presented by minisatellite DNA probe 33.15 of two placentas, tumor tissue, and parents. All polymorphic fragments of both placentas could be traced back to parents. However, all polymorphism bands in tumor tissues were identified to be of paternal origin *(arrows)*.

weighing 275 gm. They died shortly after birth, and at autopsy they appeared normal. The urinary hCG levels were 110,000 IU/L at delivery, 1100 IU/L at 1 week after spontaneous abortion, and normal at 3 weeks after spontaneous abortion. The urinary hCG level is now being monitored monthly at the clinic. The zygosity of the fetuses and pathogenesis of the aborted tumor were investigated by DNA fingerprint analysis. The high-molecular-weight DNA was extracted from placental tissues, tumor tissue, and peripheral blood of the parents. DNA fingerprint analysis was performed on the extracted DNA with a minisatellite DNA probe 33.15[10] (Fig. 1). The DNA fingerprints of the placentas showed patterns that were different from each other; however, all polymorphic fragments of both placentas could be traced back to the parents, indicating that the fetuses of this pregnancy were dizygotic. All polymorphic fragments of the tumor tissue were inherited only from the father, showing that this tumor was a complete androgenic hydatidiform mole. Histopathologic examination supported this result. These results indicate that the pregnancy described here was a triplet pregnancy involving a dizygotic twin pregnancy and a complete hydatidiform mole.

Comment

There are several possible explanations for the pregnancy containing two living fetuses and a tumor with grapelike appearance: first, the coexistence of a complete hydatidiform mole and a normal twin pregnancy; second, the coexistence of a blighted ovum with diffuse hydropic change and a normal twin pregnancy; third, the coexistence of a partial hydatidiform mole with a living fetus and a normal pregnancy. Clinically, it is very important to discern the multiple pregnancy involving a complete mole from that involving a blighted ovum or partial mole. The relative risks of choriocarcinoma associated with molar pregnancy have been estimated to be 2000 to 4000 times higher than those with normal pregnancy or aborted pregnancy.[11] On the other hand, there has been increasing evidence indicating that partial hydatidiform mole may not be associated with cho-

riocarcinoma.[12] In previous studies differential diagnosis of trophoblastic tumors has been performed by histologic examination or by karyotype analysis.[13, 14] However, it is sometimes very difficult to distinguish a blighted ovum with severe hydropic change from a complete mole by histologic examination only, and karyotype analysis requires a time-consuming tissue culture for chromosomal preparation and special techniques for analysis of chromosomal banding patterns.

In this study we used a newly developed method of DNA fingerprint. DNA fingerprints are DNA polymorphisms detected by minisatellite DNA probes that were obtained by Jeffreys et al.[10] from a human genomic DNA library by hybridization screening with a 33 bp tandem repeat probe constructed from myoglobin minisatellite. Minisatellite DNA probes, including probe 33.15, can detect highly variable regions widely dispersed in human genomes and give strictly individual specific DNA polymorphism. This method has been used in the study of the pathogenesis of trophoblastic tumors, and in this case it revealed the zygosity of two fetuses and the pathogenesis of a tumor with grapelike appearance. This method has many other advantages: (1) DNA fingerprinting is a simple and rapid method, and results of genetic analysis of trophoblastic tumors or accurate zygosity determination of multiple pregnancy can be obtained within a few days, (2) DNA fingerprint analysis can be performed not only with fresh materials but also with frozen samples; (3) <0.1 gm of tissue or 0.5 ml of peripheral blood can always provide sufficient DNA for the DNA fingerprint analysis, and the extracted DNA can be preserved at 4° C for an extended time. Therefore this method is a very useful tool for zygosity determination in multiple pregnancy and genetic analysis of trophoblastic tumors. The comparisons of DNA fingerprints among the fetuses, tumor, and their parents revealed that our case was a triplet pregnancy involving a twin pregnancy of dizygosity and a complete androgenic hydatidiform mole. A summary of the results is shown in Table I, together with those of previous studies on triplet pregnancy involving molar pregnancy. As shown in Table I, all the cases of triplet pregnancy involving a complete mole, heretofore reported, are a result of ovulation-inducing therapy by clomiphene or by hMG. It is a well-known fact that clomiphene or hMG sometimes causes ovulation of more than one ovum.

The rate of ovulation of an anuclear "empty" ovum as the underlying cause of complete mole may increase by forcing ovulation of more than one ovum by clomiphene or hMG. As the number of triplet pregnancies involving a complete mole is only three, the relationship between the risks of molar pregnancy and ovulation-inducing therapy is not clear. However, the use of clomiphene and hMG is very popular in therapy for anovulation. The classic features of molar pregnancy, such as uterine enlargement in advanced cases or severe emesis, are sometimes recognized in multiple pregnancy, especially in triplet or quadruplet pregnancy. Therefore it is very important to perform careful examinations to rule out molar pregnancy when patients with multiple pregnancy after ovulation-inducing therapy have genital bleeding. More thorough investigations are required to reveal the relationship between this ovulation-inducing therapy and ovulation of an anuclear "empty" ovum.

Influence of alcohol intake on postoperative morbidity after hysterectomy

Christine Felding, MD,[c] Lars M. Jensen, MD,[a] and Hanne Tønnesen, MD[b]
Copenhagen, Denmark

Postoperative morbidity after hysterectomy was prospectively studied in 229 consecutive patients in our departments. The incidence of alcohol abuse (>60 gm of alcohol daily) and social drinking (between 25 and 60 gm of alcohol daily) was 6.5% for each. When compared with the social drinkers and the control group, the alcohol abuse group had significantly more complications (80% vs 27% and 80% vs 13%, respectively). (Am J Obstet Gynecol 1992;166:667-70.)

Key words: Postoperative morbidity, alcohol abuse, hysterectomy

Recent studies have retrospectively shown that male alcoholics develop significantly more complications after both major and minor, elective and emergency surgery.[1-3] However, the knowledge of outcome after operation in alcoholic women is sparse. Therefore the aim of this study was to investigate the influence of alcohol intake on postoperative morbidity in women after hysterectomy.

Material and methods

This prospective study included 229 consecutive patients who underwent elective hysterectomy (from Nov. 1, 1988, to Oct. 31, 1989) at two Copenhagen centers. The indications were benign or malignant tumor or adenomyosis and endometriosis. Patients undergoing acute subtotal or vaginal hysterectomy or hysterectomy combined with colporrhaphy were not included. The patients were interviewed preoperatively on present and previous smoking habits and daily alcohol consumption. According to the actual consumption (i.e., up to the admission for hysterectomy) the patients were divided into three groups: light drinkers who drank <25 gm (fewer than two Danish drinks) of alcohol daily, moderate drinkers who consumed between 25 and 60 gm of alcohol a day, and patients who drank ≥60 gm (five or more Danish drinks) daily and were defined as heavy drinkers (one Danish drink contains 12 gm pure alcohol).

Cardiopulmonary and endocrine diseases requiring treatment were recorded, together with gynecologic symptoms and diagnoses, the surgical procedure and its duration, and blood loss and transfusion. Finally, morbidity that developed within the first 14 postoperative days was noted. Complications were defined by clinical symptoms and the need for treatment, i.e., septicemia with a generally septic condition and bacteriemia, bleeding episodes necessitating blood transfusion.

pneumonia diagnosed by stethoscope or chest roentgenogram and treated with antibiotics, and wound infection requiring intervention. Age, weight, and height were noted.

The χ^2 test and the Mann-Whitney test were used in the analysis of unpaired data. The level of significance was $p < 0.05$.

Results

The prevalences of heavy and moderate drinkers were similar, 6.5%. The three groups were comparable regarding preoperative characteristics and symptoms and diagnoses, except for fewer nonsmokers (7% vs 27% and 51%) and higher incidence of chronic bronchitis (20% vs 0% and 2%) in the heavy drinkers and more uterine fibroids in the moderate drinkers compared with the light drinkers (67% vs 39%) (Table I). There were no differences among the groups with regard to surgical procedure, duration of surgery, or perioperative blood loss and transfusion (Table I).

The heavy drinkers had significantly higher postoperative morbidity, compared with the moderate drinkers (80% vs 27%, $p \leq 0.01$, χ^2 test) and the light drinkers (80% vs 13%, $p \leq 0.01$) (Table II). There was no difference in postoperative morbidity between the moderate and light drinkers.

Regional infections were the most frequent complications seen in all three groups. Wound infection, cys-

*$p \leq 0.001$, χ^2, when compared with the control group.

titis, pneumonia, and vaginal abscess developed in 67% of the heavy drinkers, 20% of the moderate drinkers ($p \leq 0.01$), and 10% of the light drinkers ($p \leq 0.001$). However, no patient had generalized infection, and there was no perioperative mortality. The heavy drinkers had significantly prolonged hospital stays (Table II).

Finally, the light drinkers were divided according to smoking habits, but there was no difference in postoperative morbidity between smokers and nonsmokers (15% vs 11%).

Comment

Our study clearly demonstrates that the overall complication rate is heightened in female patients who are heavy drinkers (i.e., ≥60 gm of alcohol a day). Smoking may also be a part of the explanation for the increased postoperative morbidity of the alcohol-drinking group because of fewer nonsmokers in this group, corresponding to the association between smoking and alcohol abuse.[1] The heavy drinkers suffered more often from chronic bronchitis. However, the incidence of respiratory complications and cough-induced wound rupture was not significantly increased in this group. The high complication rate among the heavy drinkers is in accordance with recent studies on alcoholic men undergoing surgery.[2-4] In these retrospective materials the alcoholic groups (consuming ≥60 gm alcohol daily) were matched to control patients (drinking <25 gm alcohol daily) regarding smoking habits, thus minimizing a possible influence of tobacco on complications after surgery. Furthermore, smoking did not influence the development of complications after surgery in the control group. We therefore speculate that alcohol intake, compared with smoking, might be a dominant factor in the etiology of postoperative morbidity.

The most frequent complication was wound infection, possibly because of the fact that alcohol interferes with normal immune host defense mechanism.[5]

Alcohol also has an inhibitory effect on hemostatic function,[6] but we failed to demonstrate more bleeding episodes among the heavy drinkers.

The postoperative morbidity of our light drinkers corresponds to the incidence of complications in the control groups from other studies, except for simple pyrexia or febrile morbidity, which we did not measure as a specific complication.[7-10] Also the hospital stay after surgery in the light drinkers is in agreement with that for control patients in other investigations.[8, 11] However, in these studies a history of alcohol habits was not mentioned.

There are few reports of alcohol consumption in women with gynecologic diseases. Halliday et al.[12] found that alcohol abuse is common in women seeking gynecologic care, and Moore et al.[13] found that 12.5% of patients in gynecologic and obstetric departments were alcohol abusers, drinking >50 drinks a week. We found only a 6.5% incidence of heavy drinkers and 6.5% of moderate drinkers, but our study group was older and admitted for elective operation, which may influence the incidence of alcohol abuse.

Studies concerning alcohol intake are often defective because of underestimated self-reports of consumption. Especially among heavy drinkers there is a tendency to minimize abuse.[14] Because alcohol consumption is underestimated in self-reports, one might expect that some patients from the light drinkers, in fact, belong to the heavy drinking group, whereas the reverse situation seems unlikely. Since the study showed remarkable differences in morbidity between the light and heavy drinkers, the problem of uncertain self-reports should not change the conclusion.

The presented data call for more extensive preoperative evaluation concerning drinking habits to point out a group at special risk during surgery.

Effects of β-hydroxybutyrate infusion on hind limb metabolism in fetal sheep

Jane E. Harding, MB, ChB, DPhil,[a] Valerie E. Charlton, MD,[b] and Pandora C. Evans, MSc[a]
Auckland, New Zealand, and San Francisco, California

OBJECTIVES: This study investigated the effects of high ketone levels on fetal carcass metabolism. Specifically, we aimed to determine whether β-hydroxybutyrate was taken up by fetal muscle and whether lactate production by the fetal hind limb contributed to the raised circulating lactate levels seen in high ketone states.
STUDY DESIGN: Hind limb metabolism was studied in 10 chronically catheterized fetal sheep. Substrate/oxygen quotients were measured before and after 2 hour infusions of β-hydroxybutyrate and compared with the Wilcoxon signed-rank test.
RESULTS: β-Hydroxybutyrate was taken up by hind limb tissues in large amounts (butyrate/oxygen quotient = 1.02 ± 0.40). Lactate was produced by the hind limb (lactate/oxygen quotient = −0.96 ± 0.52) in amounts almost equivalent to glucose uptake (glucose/oxygen quotient = 1.32 ± 0.29). Hind limb oxygen consumption increased 35% and fetal arterial oxygen content fell 16%.
CONCLUSION: β-Hydroxybutyrate may be consumed by the fetal carcass in amounts sufficient to entirely substitute for glucose. Glucose may then be released as lactate for metabolism elsewhere. Ketones may be important fetal substrates during maternal starvation. (Am J Obstet Gynecol 1992;166:671-6.)

Key words: Ketones, fetal carbohydrate metabolism, lactate, fetal sheep

The ketones, β-hydroxybutyrate and acetoacetate, provide important alternatives to glucose as metabolic substrates during starvation in many mammalian species. In pregnancy, maternal ketosis occurs frequently, and ketones cross the placenta in a number of species, including human, to form potential alternative substrates for fetal metabolism.[1] Ketones are readily taken up by several fetal tissues, including muscle and liver,[1, 2] and may be an important substrate for fetal brain metabolism when glucose concentrations are low.[3]

However, in humans maternal ketosis is associated with poor fetal outcome.[4, 5] Studies in sheep have shown that direct infusion of β-hydroxybutyrate to the ewe or fetus may be associated with reduced fetal oxygenation and consistently results in a rapid and prolonged rise in circulating lactate concentrations.[3, 6-9] The reason for this rise in lactate is unknown. Lactate is an important fetal substrate under normal circumstances and is both consumed from the placenta and produced by fetal tissues in large amounts.[10-12] The magnitude of the change in fetal lactate concentrations during ketone infusion suggests that carbohydrate metabolism must be affected in major fetal organs. The most likely possibilities include inhibition of lactate uptake in the fetal liver or increased lactate production in fetal placenta or muscle. Since the carcass (mainly muscle) constitutes approximately 70% of body weight in fetal sheep,[13, 14] we chose to explore this last possibility by studying the effects of ketone infusion on hind limb metabolism in fetal sheep. We aimed to determine whether β-hydroxybutyrate was taken up by fetal muscle and whether lactate production by the fetal hind limb contributed to the raised circulating lactate levels seen during these infusions.

Material and methods

Animal preparation. Ten pregnant ewes were surgically prepared while they were under either general anesthesia (althesan induction, 2% halothane in oxygen maintenance) or spinal anesthesia (1% tetracaine hydrochloride with intravenous pentobarbital sodium and ketamine hydrochloride sedation as required). Polyvinyl catheters were placed in a maternal femoral artery and vein or carotid artery and jugular vein. Hysterotomy was performed through a midline abdominal incision, and polyvinyl catheters were placed in a fetal femoral artery and vein through the tarsal artery and vein using 1% xylocaine for local anesthesia. An ad-

ditional infusion catheter was placed in another fetal vein, usually the brachial. The uterine and maternal abdominal incisions were then closed.

Ewes were allowed to recover for at least 5 days after surgery. They were housed individually with free access to food and water. Catheters were flushed daily with heparinized saline solution. Antibiotics (penicillin and gentamicin) were given daily to the ewe and fetus for 3 to 5 days after surgery.

At the end of all studies the ewes were killed with an overdose of thiopental sodium. The position of the catheters was carefully checked to ensure that the fetal femoral catheters lay in either the femoral or internal iliac vessels. Thus the blood sampled represented that supplying and draining only the hind limb. The fetus was then weighed and dissected. The catheterized hind limb was removed by dividing the tissues at the level of the femoral head and placed in formalin.

All aspects of the experimental protocols and animal handling were approved by the Animal Ethics Committee of the institutions in which the experiments were performed.

Experimental protocols. Eleven experiments were performed in 10 animals at 121 to 139 days' gestation (130 ± 2.1 days, mean ± SEM). Each experiment consisted of a 2-hour infusion of sodium β-hydroxybutyrate, followed by a 2-hour recovery period. Sodium β-hydroxybutyrate was made up in distilled water, neutralized to pH 7.4, and infused through a 0.45 μm filter through the fetal venous catheter after an initial 1 ml bolus. The concentration was calculated to give 0.1 mmol/kg of estimated fetal weight per minute when infused at 0.1 ml/min.

Blood samples were taken immediately before and at hourly intervals during the 4-hour study period from the maternal artery and fetal femoral artery and femoral vein. In five animals, radiolabeled microspheres (15 μm, Minnesota Mining & Manufacturing, St. Paul, Minn.) were injected through the femoral venous catheter before and after the 2-hour infusion period for measurement of blood flow. The reference sample was drawn from the femoral artery.

Samples. Samples for blood gas analysis (0.4 ml) were drawn into 1-ml heparinized syringes on ice and immediately analyzed in duplicate with a Corning 158 (Corning Diagnostic, Medfield, Mass.) or Radiometer ABL 330 blood gas analyzer and a Radiometer OSM2 hemoximeter (Radiometer, Copenhagen). Blood samples for metabolite assays (1.4 ml) were drawn into heparinized syringes and immediately deproteinized on ice. Samples were then centrifuged at 4° C and the supernatant decanted and frozen at −70° C until assay.

All assays were performed in duplicate, and all samples from one experiment were assayed in the same batch. Glucose was measured with a glucose oxidase method, and lactate and pyruvate were measured with standard enzymatic spectrophotometric techniques (Sigma Chemical Co., St. Louis). β-Hydroxybutyrate was determined by the iron-chelate method.[15] The mean percentage errors between duplicate samples were glucose 3.0, lactate 2.5, pyruvate 10.7, and β-hydroxybutyrate 3.7.

For measurement of hind limb blood flow, tissues were carbonized at 325° C for at least 24 hours, powdered, and packed into vials for counting on an Ultima II Multichannel Pulse Height Analyser (Ino Tech, Co., Fort Atkinson, Wis.). Isotopes used included chromium 51, strontium 85, niobium 95, manganese 54, zinc 65, gadolinium 153, and indium 114. Blood flow to the hind limb was calculated from counts in the reference sample.[16, 17]

Calculations. Blood oxygen contents were calculated from measured P_{O_2}, hemoglobin, and oxygen saturations. Metabolite concentrations were all expressed as the mean of duplicate samples. Hind limb substrate/oxygen quotients were calculated as the arteriovenous difference for the substrate across the hind limb × K divided by the arteriovenous difference for oxygen, where K = 6 for glucose, 3 for lactate and pyruvate, and 4.5 for β-hydroxybutyrate.

All results for the two experiments performed on one of the animals were averaged, and this single average value was used in statistical analyses. Hind limb substrate uptakes were calculated as the arteriovenous substrate difference × the blood flow per 100 gm of tissue.

Preinfusion values were compared with values obtained during and after infusions using the Wilcoxon signed-rank test for paired data. All values are expressed as the mean ± standard error of the mean.

Results

Infusion of β-hydroxybutyrate into the fetus resulted in a 54-fold rise in arterial β-hydroxybutyrate concentrations (0.09 ± 0.01 at 0 hour to 5.41 ± 0.88 mmol at 2 hours, $p < 0.001$), which fell during the 2-hour recovery period (0.92 ± 0.31 mmol at 4 hours). Lactate and pyruvate concentrations both rose more than twofold during the infusion and continued to rise during the recovery period (Table I, Fig. 1). Fetal arterial concentrations of glucose and oxygen were unchanged during the infusion, but there was a 14% rise in glucose concentration and a 16% fall in oxygen content by the end of the recovery period (Table I, Fig. 1). There were no changes in fetal pH (7.35 ± 0.01) or blood gases (P_{O_2} = 20.0 ± 1.3) at any time during the studies and no change in any of the maternal blood gas and metabolite concentrations measured (maternal pH = 7.46 ± 0.01, P_{O_2} = 109.5 ± 4.3 torr, β-hydroxybutyrate = 1.08 ± 0.23 mmol/L, glucose =

†$p < 0.05$ for comparison with value before beginning infusion (0 hour).
‡$p = 0.067$ for comparison with value before beginning infusion (0 hour).

3.03 ± 0.24 mmol/L, lactate = 0.81 ± 0.09 mmol/L, pyruvate = 0.04 ± 0.01 mmol/L).

β-Hydroxybutyrate infusion resulted in a significant arteriovenous difference for β-hydroxybutyrate across the hind limb, so that by the end of the infusion β-hydroxybutyrate uptake could have accounted for all oxidative requirements of the hind limb (butyrate/oxygen quotient at 2 hours = 1.02 ± 0.40). However, this uptake was closely matched by an increased output of lactate by the hind limb (lactate/oxygen quotient at 2 hours = −0.96 ± 0.52). The glucose/oxygen quotient across the hind limb (1.32 ± 0.29) was unchanged throughout the study. There was no significant arteriovenous difference for pyruvate at any time across the hind limb, and no significant change in the arteriovenous difference for oxygen (Table I). Thus the total calculated substrate/oxygen quotient across the hind limb, the sum of the quotients for β-hydroxybutyrate, lactate, glucose and pyruvate, was unchanged throughout the study (1.52 ± 0.27 at 0 hour, 1.36 ± 0.98 at 2 hours, and 1.26 ± 0.47 at 4 hours, Fig. 2).

The mean blood flow to the hind limb for the five animals in which it was measured was 38.9 ± 5.4 ml/min/100 gm and did not change after β-hydroxybutyrate infusion (36.7 ± 6.5 ml/min/100 gm at 2 hours). β-Hydroxybutyrate uptake across the hind limb reached 7.3 ± 3.5 μmol/min/100 gm by the end of the infusion, a figure almost exactly matched by the simultaneous hind limb output of lactate (6.6 ± 2.7 μmol/min/100 gm) and greater than the simultaneous uptake of glucose (4.7 ± 0.9 μmol/min/100 gm). There was no significant uptake of pyruvate. Hind limb oxygen uptake increased by 35% by the end of the infusion (Table I).

Comment

This study has shown that β-hydroxybutyrate may be taken up in large amounts by the tissues of the fetal hind limb. In spite of this large uptake of an alternative substrate, the total hind limb substrate/oxygen quotient was unchanged. β-Hydroxybutyrate uptake was matched by a substantial production of lactate, and there was no change in hind limb glucose uptake. Because the coefficients of extraction for the measured substrates were low across the hind limb, the methodology used in this study may allow substantial errors in the calculation of metabolic balances such as are attempted here. Radiolabeled tracer turnover studies are required to confirm our observations. Nevertheless, the data are consistent with other published studies and with what is known about the metabolic pathways involved (see below).

The lactate production by the hind limb is likely to have been from carbon originating in glucose rather than β-hydroxybutyrate. β-Hydroxybutyrate is metabolized to acetyl-coenzyme A, which in mammalian tissues cannot be converted to pyruvate and hence lactate.[18] On the other hand, glucose is normally metabolized to pyruvate before entry to the citric acid cycle.

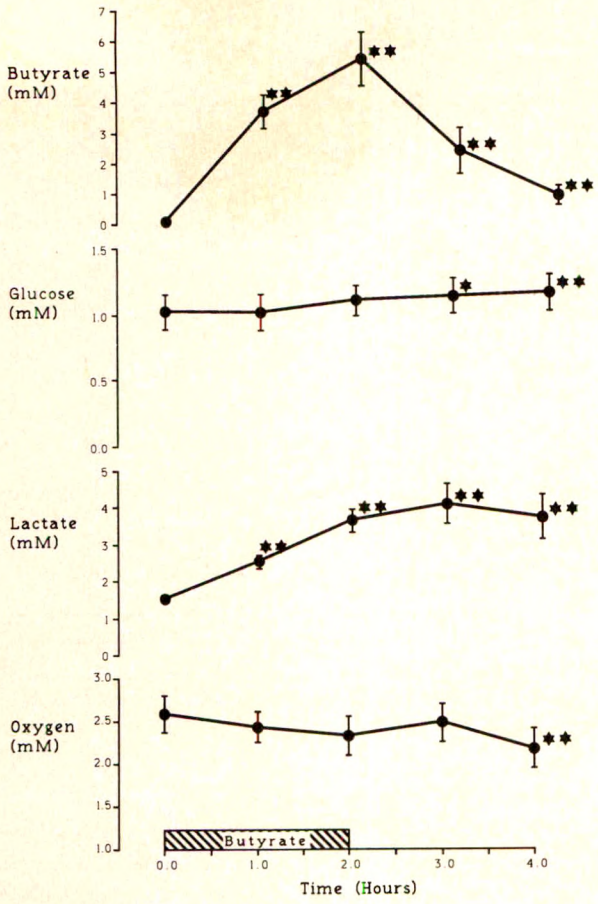

Fig. 1. Changes in fetal arterial substrate and oxygen concentrations during and after β-hydroxybutyrate infusion. Figures are mean ± SEM for 10 studies. β-Hydroxybutyrate was infused during the first 2 hours *(hatched bar)*. *Asterisk*, $p < 0.05$; *double asterisk*, $p < 0.01$ for comparison with value before beginning infusion (0 hour).

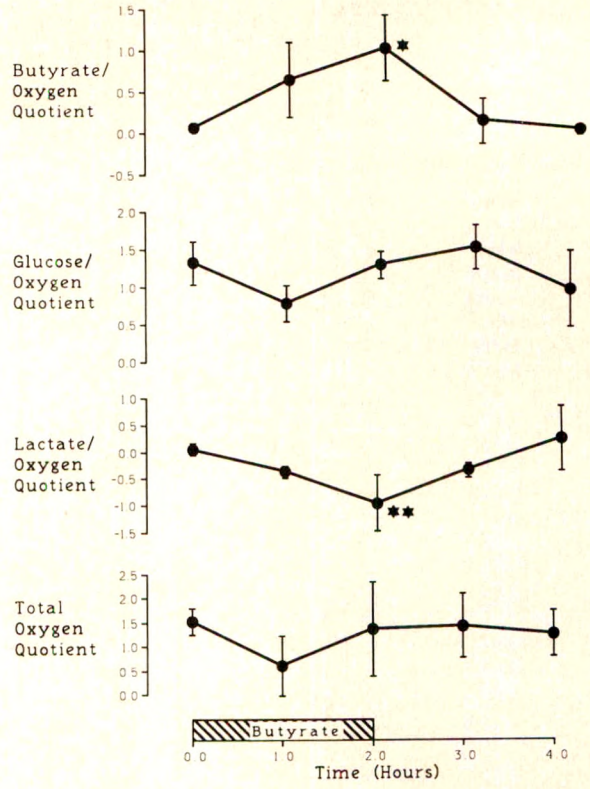

Fig. 2. Changes in fetal hind limb substrate/oxygen quotients during and after β-hydroxybutyrate infusion. Figures are mean ± SEM for 10 studies. β-Hydroxybutyrate was infused during the first 2 hours *(hatched bar)*. *Asterisk*, $p < 0.05$; *double asterisk*, $p < 0.01$ for comparison with value before beginning infusion (0 hours).

In the presence of β-hydroxybutyrate, this pyruvate may instead be converted to lactate due to inhibition of pyruvate dehydrogenase by accumulating acetyl-coenzyme A and the reduced form of α-nicotinamide adenine dinucleotide.[1, 18] Thus it is likely that during β-hydroxybutyrate infusion, glucose is metabolized to pyruvate and then to lactate by the hind limb tissues, whereas β-hydroxybutyrate, through acetyl-coenzyme A, enters the citric acid cycle, substituting for glucose in providing unchanged total substrate supplies for oxidative metabolism. This mechanism would provide an efficient pathway by which, when ketones are available, they could be used as alternative substrates by fetal muscle. Glucose carbon could then be released as lactate for uptake by other tissues, maintaining carbohydrate in the fetal circulation because lactate does not cross the placenta easily. This released lactate may substitute for glucose as a substrate in other fetal tissues, such as liver[19] or heart,[20, 21] and thus reduced tissue use of glucose may account for the observed rise in circulating fetal glucose concentrations during these studies.

An estimate of the magnitude of this substitution of substrates can be obtained from these studies. Assuming hind limb tissues are representative of whole carcass, which forms approximately 70% of body weight in fetal sheep,[13, 14] then the estimated carcass uptake of glucose in these studies (30 to 50 μmol/min/kg) is in the range of estimated whole body uptake of glucose by the fetal sheep across the placenta.[22-24] This glucose then appears to be converted by the carcass to lactate in amounts (46 μmol/min/kg) that are also similar to the total lactate uptake from the placenta.[10-12] Carcass uptake of β-hydroxybutyrate (51 μmol/min/kg) accounts for approximately half of the infused butyrate (100 μmol/min/kg), suggesting that other tissues in either the fetus or placenta may be taking up butyrate. There is also accumulation of butyrate in the circulation and probably some loss across the placenta and metabolism in maternal tissues. Thus provision of β-hydroxybutyrate to the fetus may enable the carcass to substitute butyrate for a major proportion of its glucose

uptake and allow lactate release in amounts similar to those normally acquired by the fetus from the placenta.

In this study the large lactate release from fetal tissues was not accompanied by any change in fetal pH and resulted in a modest (16%) fall in fetal arterial oxygen content. This is in contrast with previous studies in which β-hydroxybutyrate infusion into the pregnant ewe or fetus resulted in much larger falls in fetal Po_2.[7-9] There are a number of possible reasons for this difference. Miodovnik et al.[7-9] infused larger doses of β-hydroxybutyrate in their experiments and may have observed larger changes in fetal oxygenation for this reason. They also gave simultaneous infusions of antipyrine. Because both β-hydroxybutyrate[7] and antipyrine infusions[25] may be associated with reduced placental blood flow, the combination may have contributed to the observed fall in fetal Po_2. Those studies also resulted in larger rises in fetal blood glucose concentrations than we observed. It is not clear whether this higher glucose was the result of the higher β-hydroxybutyrate dose infused and may itself have contributed to the greater fall in fetal Po_2 or whether the observed greater fetal hypoxemia contributed to the greater rise in blood glucose levels.[7, 8] Whatever the mechanism, it appears that fetal β-hydroxybutyrate infusion is associated with increased hind limb oxygen consumption and impaired fetal oxygenation in what may be a dose-dependent fashion. This may contribute to the poor perinatal outcome in the diabetic pregnancy.

The mean glucose/oxygen quotient measured across the hind limb in these studies was 1.32, suggesting that glucose was taken up in excess of hind limb oxygen requirements. This is consistent with previous studies in fetal sheep, showing that the glucose/oxygen quotient across the hind limb is proportional to the fetal arterial glucose concentration.[14, 26] Indeed, our results are remarkably consistent with the regression equation calculated by Morriss et al.[26]; using their equation, the expected hind limb glucose/oxygen quotient for our data would be 1.43. The fate of the glucose which is taken up in excess of oxidative requirements is not known, but it may perhaps be stored as glycogen or fat to meet later postnatal carbohydrate needs.

In summary, we have shown that β-hydroxybutyrate is taken up in large quantities by the tissues of the fetal hind limb. It appears to almost completely substitute for glucose as an oxidative fuel, resulting in lactate release. This is associated with increased hind limb oxygen consumption and reduced fetal arterial oxygen content. Ketones may be important fetal substrates during times of inadequate glucose supply, such as during maternal starvation.

We thank M. de Carlo, M. Johengen, L. Li, and F. Powell for technical assistance.

OBJECTIVE: The purpose of this study was to study the role of transforming growth factor–β in regulation of proliferation of normal and malignant ovarian epithelial cells.
STUDY DESIGN: We examined production of and responsiveness to transforming growth factor–β in primary monolayer cultures of epithelial cells from five normal human ovaries and in five ovarian cancer cell lines.
RESULTS: In normal ovarian epithelial cells, proliferation always was inhibited by transforming growth factor–β (>40%) ($p < 0.01$). Among the cancer cell lines, proliferation of one was markedly inhibited (>95%) ($p < 0.01$), two were only modestly inhibited (15% to 20%) ($p < 0.05$), and two were unaffected. In addition, we found that all of the normal ovarian epithelial cells and four of five ovarian cancer cell lines produce transforming growth factor–β ribonucleic acid and protein.
CONCLUSIONS: These data suggest that transforming growth factor–β may act as an autocrine growth inhibitory factor for normal ovarian epithelium in vivo. Because most of the ovarian cancer cell lines are relatively resistant to the growth inhibitory effect of transforming growth factor–β and because one cell line does not produce transforming growth factor–β, it is possible that loss of the transforming growth factor–β pathway may play a role in the development of some ovarian cancers. (Am J Obstet Gynecol 1992;166:676-84.)

Key words: Ovarian cancer, growth inhibitor, transforming growth factor-β

Transforming growth factor–β (TGF-β) initially was discovered in the culture media of virally transformed cells. It was called a transforming growth factor due to its ability to act in concert with TGF-α to elicit malignant transformation of some normal nontransformed cells. Subsequently, however, it has been demonstrated that TGF-β also is produced by a wide range of normal cells. Molecular cloning of TGF-β has revealed three closely related forms (TGF-β_1, TGF-β_2, TGF-β_3), all of which are composed of two amino acid chains held together by disulfide bonds. In addition, it has been shown that TGF-β is secreted in an inactive form noncovalently bound to a portion of its precursor, from which it must be released to produce biologically active TGF-β.[2]

Although TGF-β initially was discovered due to its ability to induce the transformed phenotype in some normal cells, the predominant effect of TGF-β on most normal cells in vitro is inhibition of proliferation. It has been proposed that TGF-β may also act as a growth inhibitory factor in vivo; however, the sites of origin and physiologic role of TGF-β in various organ systems is not yet entirely clear. In addition, it has been proposed that the unrestrained proliferation of some cancers may, in part, be due to loss of normal growth

inhibitory pathways such as TGF-β.[2] This hypothesis also needs to be tested rigorously.

In the rodent ovary, it has been shown that both granulosa and theca cells produce TGF-β and that TGF-β regulates both proliferation and responsiveness to gonadotropins of granulosa cells.[3-6] Production of and responsiveness to TGF-β in ovarian epithelial cells, from which the majority of ovarian cancers in the United States arise, has not previously been studied, however. In addition, although it is appreciated that epithelial ovarian cancers spread intraperitoneally due to implantation and growth of cells exfoliated by the primary ovarian neoplasm, the factors that regulate the growth of ovarian cancers remain poorly understood. We have performed a series of experiments designed to investigate the role of TGF-β in growth regulation and transformation of human ovarian epithelium.

Material and methods

Cell culture. Five epithelial ovarian cancer cell lines previously established in our lab (OVCA 420, OVCA 429, OVCA 432, OVCA 433, DOV 13) were routinely cultured in modified Eagle's medium supplemented with 10% heat-inactivated fetal bovine serum. Primary monolayer cultures of normal human ovarian epithelial cells from five patients were established as previously described.[7, 8] Briefly, the surface of the ovary was scraped gently, and the epithelial cells were then plated in a 1:1 mixture of MCDB 105/M199 medium supplemented with 15% heat-inactivated fetal bovine serum and epidermal growth factor (10 ng/ml). Cells were cultured at 37° C in 5% carbon dioxide and 95% humidified air.

Collection of conditioned culture medium. Each of the ovarian cancer cell lines and normal ovarian epithelial cultures were grown to confluence in their respective culture media containing 10% fetal bovine serum. After washing the cells with Hank's buffered salt solution, the cells were grown for 48 hours in serum-free medium. The cancer cell lines were grown in Richter's serum-free medium,[9] and the normal epithelial cells were grown in serum-free MCDB 105/M199 medium without epidermal growth factor. After 48 hours, the conditioned medium was removed and stored at −70° C. Before testing conditioned media for the presence of TGF-β, media from each of the cells was divided into two aliquots; one of which was heated at 90° C for 10 minutes while the other was untreated. The conditioned media were then dialyzed, lyophilized, and reconstituted at a fivefold increased concentration in medium containing 2% fetal bovine serum. The reconstituted media each were added to six replicate wells of CCL-64 cells, which are known to be growth inhibited by TGF-β,[10] to test for the presence of active TGF-β. Serum-free media that had not been exposed to cells was processed in an identical manner and used as a negative control. Authentic porcine TGF-β_1 (R & D Systems, Minneapolis, Minn.) was used as a positive control.

Immunohistochemistry. Frozen sections were obtained from three normal human ovaries that were removed at the time of hysterectomy for benign gynecologic diseases. Immunohistochemical staining for TGF-β was performed with the Vectastain ABC kit (Vector Laboratories, Burlingame, Calif.) as described previously.[11] Monoclonal antibody ID11.16 (Collagen Corporation, Palo Alto, Calif.) which recognizes the mature forms of both TGF-β_1 and TGF-β_2, was used as the primary antibody (5 μg/ml).[12] Purified mouse immunoglobin G specific for nonhuman tissue (Coulter Immunology, Hialeah, Fla.) was used as a negative control (1:100 dilution). Anticytokeratin AE1/AE3 (Boehringer Mannheim Biochemicals, Indianapolis, Ind.) was used as a positive control. The slides were developed for 4 minutes with the enzyme substrate diaminobenzidine (0.5% diaminobenzidine in 0.05% Tris buffer, 0.6% hydrogen peroxide). Slides then were rinsed in water, counterstained with methyl green, dehydrated, and mounted.

[^{3}H]thymidine assay. Each of the five ovarian cancer cell lines and CCL-64 cells were grown in supplemented modified Eagle's medium containing 2% fetal bovine serum in 96-well culture plates (5×10^4 cells/well). Normal ovarian epithelial cells were grown in MCDB 105/M199 medium containing 2% FBS. Authentic porcine TGF-β_1 (0, 0.2, 2, 10, or 20 ng/ml) (R & D Systems, Minneapolis, Minn.) or antibody was added at the time of plating to six replicate wells containing CCL-64 cells. Anti-TGF-β antibodies used included a polyclonal antisera (R & D Systems) and monoclonal antibody 1D11.6 (Collagen Corporation). Both of these reagents neutralize TGF-β_1 and TGF-β_2. In several experiments, A2C6 (Centocor, Malvern, Pa.), a murine monoclonal antibody raised against a human hepatitis B virus, was used as a negative control. The cells were grown for 48 hours. During the last 4 hours of culture, 1 μCi of [^{3}H]thymidine (6.7 Ci/mmol/L) was added to each well. The culture medium was then removed. Cells were washed three times with phosphate-buffered saline solution and harvested. Incorporated radioactivity was measured in a Packard liquid scintillation counter.

Ribonuclease protection assay. Cells were grown to confluence in medium containing 10% fetal bovine serum. Ribonucleic acid (RNA) was prepared after lysis of cells in a hypotonic solution with the nonionic detergent Nonidet P-40 supplemented with 200 μg/ml heparin (Sigma Chemical Co., St. Louis, Mo.) as a ribonuclease inhibitor. RNA was quantitated by absorbance at 260 nm. Analysis of total RNA by the ribonuclease protection assay was performed according to published protocol, with some optimizing changes.[13] Briefly, 10 μg cellular RNA plus 20 μg transfer RNA

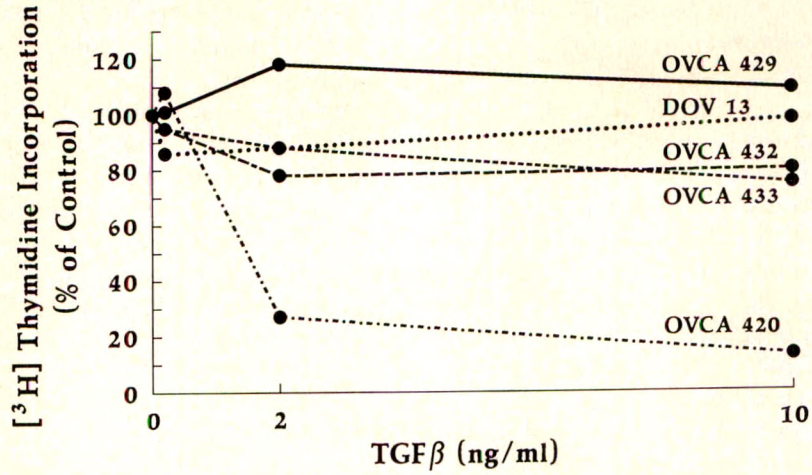

Fig. 1. Effect of TGF-β on proliferation of ovarian cancer cell lines (OVCA 420, $p < 0.01$; OVCA 432, OVCA 433, $p < 0.05$; OVCA 429, DOV 13, not significant).

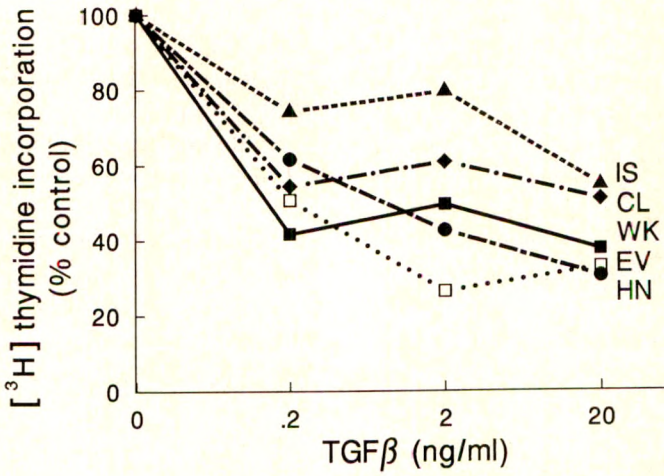

Fig. 2. Effect of TGF-β on proliferation of normal human ovarian epithelial cells ($p < 0.01$).

was combined with phosphorus 32–labeled complementary RNA (1.5 to 2 × 10^5 counts/min) in 30 μl hybridization buffer, heated to 85° C for 5 minutes, and then incubated at 53° C overnight. Ribonuclease digestion was carried out by the addition of 350 μl of ice-cold digest buffer, containing 0.24 units/ml ribonuclease A and 80 units/ml ribonuclease T_1, and proceeded for 30 minutes at 35° C. Ribonuclease A and T_1 and transfer RNA were from Boehringer Mannheim (Indianapolis, Ind.). Samples were then treated with proteinase K, extracted with phenol/chloroform, and precipitated with ethanol. Samples were dissolved in gel-loading buffer and fractionated by electrophoresis with 4.5% polyacrylamide-6 mol/L urea sequencing gels, each lane containing the equivalent of 6 μg of inital cellular RNA. Control samples, processed concurrently with authentic samples, contained transfer RNA alone (negative control) or transfer RNA plus a mixture of sense complementary RNAs prepared by in vitro transcription of complementary DNA for TGF-β_1, β_2, and β_3 positioned downstream of the SP6 promoter (positive control). The use of sense complementary RNAs containing full-length coding sequences for each of the three human TGF-βs demonstrated the lack of cross hybridization between the three TGF-β probes (data not shown). The preparation of TGF-β probes for the ribonuclease protection assay has been described previously.[14] RNA probes were stored in water at −70° C and used within 4 to 7 days of preparation. For ribonuclease protection assays, probes for TGF-β_1 and β_2 were mixed together (1.5 × 10^5 counts/min each/sample) since the diagnostic ^{32}P-labeled fragments

could be easily distinguished by size. The probe for TGF-β_3 was hybridized with samples separately (2×10^5 counts/min/sample).

Statistics. The Student *t* test was used to analyze experiments in which mean values were compared.

Results

The effect of TGF-β on [^{3}H]thymidine incorporation of the five ovarian cancer cell lines and normal ovarian epithelial cells is shown in Figs. 1 and 2. TGF-β markedly inhibited [^{3}H]thymidine incorporation (>90%) in OVCA 420 cells ($p < 0.01$), whereas OVCA 432 and OVCA 433 cells were only modestly inhibited (15% to 20%) ($p < 0.05$). Proliferation of OVCA 429 and DOV 13 cells was unaffected by TGF-β (Fig. 1). In normal ovarian epithelial cells from five patients, TGF-β inhibited incorporation of [^{3}H]thymidine by >40% in all cases ($p < 0.01$) (Fig. 2). In all experiments, TGF-β (2 to 10 ng/ml) inhibited [^{3}H]thymidine incorporation of CCL64 cells (the positive control) by >95% (data not shown).

Immunohistochemical staining for TGF-β with a monoclonal antibody reactive with both TGF-β_1 and TGF-β_2 is shown in Fig. 3. In Fig. 3, *A*, staining for TGF-β is seen in placenta, which is known to produce large amounts of TGF-β (positive control). In Fig. 3, *B*, immunohistochemically detectable TGF-β is seen in a cytospin preparation of OVCA 420 cells. Staining for TGF-β also was seen in each of the other ovarian cancer cell lines except OVCA 432 (data not shown). In Fig. 3, *C*, immunoreactive TGF-β is seen in the epithelium in a frozen section of normal human ovary. Immunohistochemically detectable TGF-β also was seen in cytospin preparations of cultured normal ovarian epithelial cells.

Expression of TGF-β messenger RNA by the ovarian cancer cell lines is shown in Figs. 4 and 5. TGF-β_1 and TGF-β_2 messenger RNA were present in OVCA 420, OVCA 429, OVCA 433, and DOV 13 cells (Fig. 4). In contrast, OVCA 432 cells do not contain TGF-β_1 messenger RNA and only a faint TGF-β_2 band is seen. In Fig. 5, TGF-β_1 and TGF-β_2 transcripts are seen in RNA derived from normal ovarian epithelial cells from two patients. In addition, the appropriate positive and negative controls that were described in the material and methods section are shown in Fig. 5. Although a TGF-

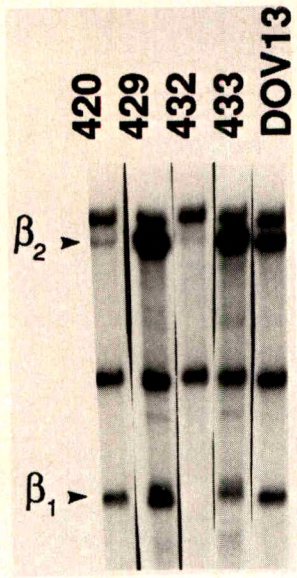

Fig. 4. TGF-β messenger RNA expression in ovarian cancer cell lines.

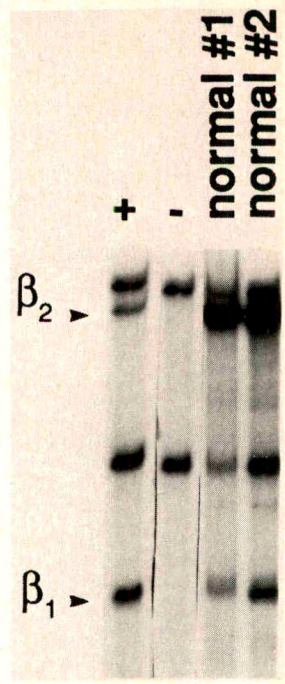

Fig. 5. TGF-β messenger RNA expression in normal ovarian epithelial cells from two patients along with positive and negative controls.

β_3 band was seen in the lane representing the positive control, none of the ovarian cancer cell lines or normal ovarian epithelial cells were found to produce TGF-β_3 messenger RNA (data not shown).

Previously, we have shown that among the five ovarian cancer cell lines, only OVCA 433 cells secrete biologically active TGF-β.[15] In the current study, we examined whether the ovarian cancer cell lines secrete latent TGF-β that can be activated by heating. The effect of fivefold concentrated heated conditioned culture medium from each of the ovarian cancer cell lines except DOV 13 (not done) on [^{3}H]thymidine incorporation of CCL64 cells is compared with that of unheated medium (Fig. 6). Heating resulted in generation of TGF-β–like activity in conditioned media from all but one of the ovarian cancer cell lines relative to unheated media, which is respresented as 100% of control in Fig. 6 ($p < 0.05$). OVCA 432, which does not produce appreciable amounts of TGF-β messenger RNA transcripts or immunohistochemically detectable TGF-β, also was not found to produce latent TGF-β with this bioassay.

We also tested heated and unheated serum-free conditioned medium from normal ovarian epithelial cultures from two patients for the presence of active and latent TGF-β. We found that fivefold concentrates of unheated medium conditioned by epithelial cells from two normal ovaries consistently decreased [^{3}H]thymidine incorporation of CCL64 cells ($p < 0.05$). When the medium was heated before exposure to CCL64 cells, to activate latent TGF-β, an even greater inhibition of proliferation was noted (Fig. 7). In addition, the inhibition caused by the conditioned medium was reversible if anti-TGF-β monoclonal antibody (10 μgm/ml) was added to the cultures. Serum-free medium that had not been exposed to cells but which had been processed in an identical manner had no effect on [^{3}H]thymidine incorporation of CCL-64 cells (data not shown).

In Fig. 8, the effect of polyclonal anti-TGF-β antisera on [^{3}H]thymidine incorporation of four of the ovarian cancer cell lines is shown. Proliferation of three ovarian cancer cell lines that either do not express TGF-β (OVCA 432) or express only latent TGF-β (OVCA 420, OVCA 429) was not affected by the antibody. On the other hand, proliferation of OVCA 433 cells, which both secrete active TGF-β and are inhibited by exogenous TGF-β, was stimulated by the anti-TGF-β antisera ($p < 0.05$). Similar results were obtained using the monoclonal anti-TGF-β antibody (data not shown). In addition, the monoclonal anti-TGF-β antibody significantly stimulated ($p < 0.01$) [^{3}H]thymidine incorporation of normal ovarian epithelial cells from one patient (Fig. 9), whereas ovarian epithelial cells derived from another patient were not stimulated. These experiments were repeated several times with different concentrations of serum (0% to 10%), different cell densities (confluent, subconfluent), and different incubation times (24 to 48 hours). Optimal stimulation of proliferation was noted in confluent cells after 48 hours in serum-free medium. The negative control antibody A2C6 had no effect on [^{3}H]thymidine incorporation of

the cancer cell lines or the normal epithelial cells (data not shown).

Comment

Although TGF-β was discovered due to its ability to act in concert with TGF-α to transform some types of normal cells in culture,[1] TGF-β has been shown to inhibit proliferation of many normal epithelial cells.[2] In addition, TGF-β also frequently induces differentiation of epithelial cells in culture. For example, bronchial epithelial cells undergo terminal differentiation to a squamous phenotype after exposure to TGF-β.[16] The mechanism of action of TGF-β is poorly understood, however. TGF-β receptors have not been well characterized and the intracellular events that are triggered after TGF-β binding have not been defined. Although in vitro evidence suggests that TGF-β might be a physiologically important growth inhibitory substance, the role of TGF-β in normal processes of growth and differentiation remains unclear.

The potential role of TGF-β as a growth inhibitory substance has been studied extensively in breast epithelium. It has been shown that normal breast epithelial cells produce TGF-β and that TGF-β acts to inhibit proliferation of these cells.[17, 18] In addition, it has been shown that steroid hormones that inhibit growth of normal breast epithelium, such as progestins and antiestrogens, stimulate production of TGF-β.[19] Conversely, estrogens, which stimulate growth, act to inhibit TGF-β production.[14, 19] It has been proposed that the effect of circulating steroid hormones on proliferation of breast epithelium may be due to induction or suppression of production of TGF-β and other peptide growth factors.

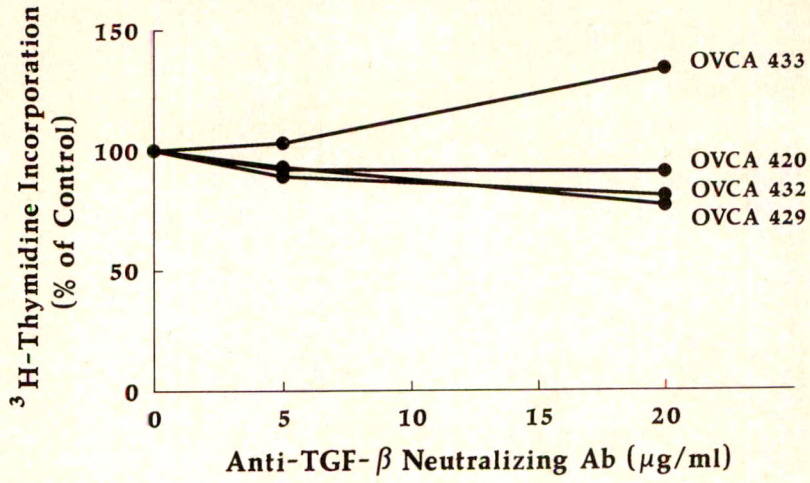

Fig. 8. Effect of polyclonal anti-TGF-β antisera on proliferation of epithelial ovarian cancer cell lines (OVCA 433, $p < 0.05$).

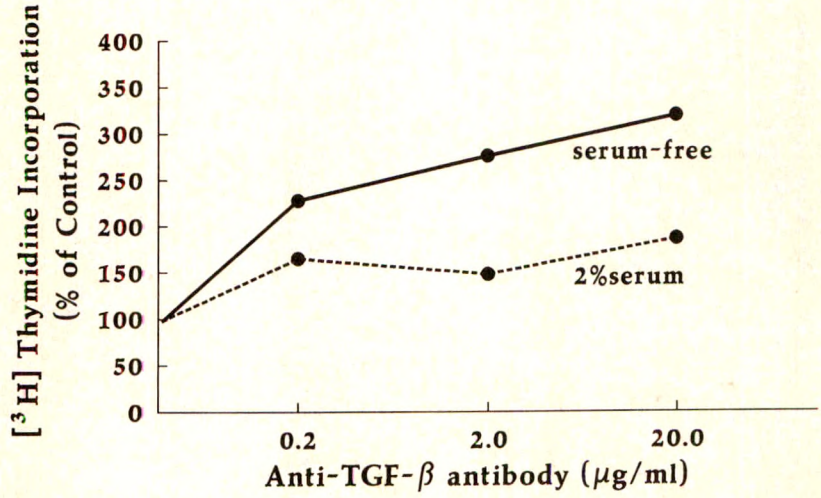

Fig. 9. Effect of monoclonal anti-TGF-β antibody on proliferation of normal ovarian epithelial cells (serum-free, 2% serum, $p < 0.05$).

In the present study we found that, like normal breast epithelium, normal ovarian epithelium produces both TGF-β_1 and TGF-β_2 and is growth-inhibited by exogenous TGF-β. These data suggest that TGF-β might act in vivo as an autocrine growth inhibitory substance that prevents inappropriate proliferation of ovarian epithelial cells, which normally are thought to proliferate relatively slowly. At the time of ovulation, this inhibitory pathway might be turned off to allow proliferation of epithelial cells to cover the defect that is caused by extrusion of the ovum through the ovarian surface. Because the levels of estrogens and progesterone in the ovary vary markedly during the cycle, we are investigating the possibility that TGF-β production by ovarian epithelial cells is regulated by steroid hormones in a manner similar to that observed in breast epithelium. In addition, our group[8] and Siemens and Auersperg[20] have shown that epidermal growth factor stimulates proliferation of normal human ovarian epithelial cells. Proliferation of ovarian epithelial cells after ovulation, or at other times, might be due to both a decrease in growth inhibitory pathways such as TGF-β and increased availability of mitogenic peptide growth factors.

We found that normal human ovarian epithelial cells sometimes, but not always, appeared to activate the latent TGF-β that they secreted into their culture medium. Further studies are needed to determine whether TGF-β produced by ovarian epithelial cells is activated in vivo. In addition, the mechanism of activation and the cell types involved also must be identified. In this regard, it is known that TGF-β is secreted from cells in a biologically inactive form noncovalently

bound to a portion of the precursor molecule from which it is cleaved during processing.[2] Furthermore, TGF-β in serum is bound to α_2-macroglobulin.[21] Although TGF-β can be activated by low pH or heating in vitro,[22] these are not thought to be physiologically relevant mechanisms of TGF-β activation. There is some evidence to suggest that proteases and glycosidases may play an important growth regulatory role in vivo by liberating active TGF-β from its precursor.[23, 24] If a cell that produces TGF-β and responds to TGF-β also produced the enzymes that activate TGF-β, it would possess all of the components of an autocrine growth inhibitory loop. On the other hand, if a cell lacked the enzymes needed to activate TGF-β, it is possible that TGF-β still might be activated in the local environment if these enzymes were produced by other nearby cells. This latter hypothesis is particularly appealing because the ovary and other human organs are comprised of several different cell types that presumably must communicate to act in a coordinated fashion.

Although increased proliferation associated with cancer may be due to inappropriate production of growth stimulatory factors, loss of growth inhibitory pathways, such as TGF-β, also could result in increased proliferation. In this regard, we found that all but one of the ovarian cancer cell lines were either partially or completely resistant to the growth inhibitory effect of TGF-β relative to normal ovarian epithelial cells. Similarly, several other transformed cells and human cancer cells that are resistant to TGF-β have been described.[25-27] In addition, although normal ovarian epithelial cells and most of the ovarian cancer cell lines produced TGF-β_1 and TGF-β_2, one of the ovarian cancer cell lines produced little, if any, TGF-β. Finally, only one of the ovarian cancer cell lines was able to activate the TGF-β that it produced. These findings suggest that loss of various components of the TGF-β pathway is common in ovarian cancer cell lines. It is possible that loss of this growth inhibitory pathway might play a role in the development of some ovarian cancers.

Prostaglandin- or endothelium-mediated vasodilation is not involved in the blunted responses of blood vessels to vasoconstrictors in pregnant rats

Jean St-Louis, PhD, and Benoit Sicotte, BSc
Montreal, Quebec, Canada

Pregnancy is associated with decreases of blood pressure and vascular sensitivity to vasopressor agents. We have hypothesized that the increased liberation of endogenous vasodilator(s) by the vascular endothelium or other structures could mediate these blunted responses. Thoracic aorta rings of nonpregnant, 21 days pregnant, and first day post partum rats respond similarly to acetylcholine, an endothelium-dependent vasorelaxant. In contrast, the potency of the response to sodium nitroprusside, an endothelium-independent vasorelaxant, is unchanged in tissues of pregnant rats and increased ($p < 0.05$) in those of post partum animals. In the presence of indomethacin (10 μmol/L) the three groups of tissues show a decreased potency. The effects of phenylephrine on aortic rings of both nonpregnant and pregnant rats are markedly increased in the presence of N^{g}-monomethyl-L-arginine. Indeed, the concentration producing 50% of the maximum response of phenylephrine decreases ($p < 0.001$) from 50.7 to 8.02, from 93.8 to 37.6, and from 60.4 to 5.97 nmol/L with the use of N^{g}-monomethyl-L-arginine (0.1 mmol/L) in rings from nonpregnant, pregnant, and postpartum rats, respectively. Simultaneously, the maximum response to phenylephrine increases markedly in the three groups of tissues. In the presence of N^{g}-monomethyl-L-arginine, indomethacin does not influence the response to phenylephrine. Our results do not support the possible involvement of an endogenous vasodilator (prostaglandin-like or endothelium-derived) in the blunted responses to vasoconstrictors during pregnancy. (Am J Obstet Gynecol 1992;166:684-92.)

In recent years, it has become clear that the endothelial lining of blood vessels performs many physiologic functions. Such an influence was first demonstrated by Furchgott and Zawadsky,[1] accounting for the vascular smooth muscle–relaxing effect of acetylcholine. It has also become evident that endothelium-dependent relaxation modulates the effects of vasoconstrictor agents[2] and mediates flow-dependent relaxation.[3] Some inhibitors of this endothelium-dependent relaxation have become available recently as, for example, N^{g}-monomethyl-L-arginine and L-argininosuccinic acid.[4]

Under physiologic conditions, such as pregnancy,

blood pressure decreases,[5, 6] possibly as a consequence of the decreased sensitivity of blood vessels to vasoconstrictor agents. This reduced sensitivity has been noted in many tissues and in some vascular beds of pregnant rats such as aorta,[7] portal vein,[8] caudal artery,[9] and pulmonary[10] and mesenteric[8] beds. This effect is not specific for a given agent, because it was observed with several vasoconstrictors, such as angiotensin, vasopressin, norepinephrine, etc.[8] This decreased sensitivity of blood vessels of pregnant rats is similar in magnitude to the blunted pressor responses to vasoconstrictors observed in conscious pregnant rats.[11-13]

The vasoconstrictor effect of many agents is reported to be diminished in the presence of the endothelium in isolated vessels.[14] Because we have recently reported that the sensitivity of mesenteric artery rings of both nonpregnant and pregnant rats to α-adrenergic agents is dependent on the functional presence of the endothelium,[15] we undertook the present experiments to further investigate the involvement of the endogenous vasorelaxant influence of the vessel wall in the blunted responses to vasoconstrictors at the end of pregnancy and in the postpartum period in the rat. In these experiments, we look particularly at endothelium-derived relaxing factor (EDRF) and arachidonate derivatives through the cyclooxygenase pathway. The end of pregnancy (twenty-first day) and postpartum period were chosen because, under these conditions, important changes occur in vascular reactivity.[7]

Methods

Ten-week-old female Sprague-Dawley rats, obtained from Charles River Canada (St-Constant, Québec), were mated with males of the same age. The morning on which vaginal smears were found to contain spermatozoa was labeled day 1 of gestation. The experiments were performed on the twenty-first day of pregnancy and between 18 and 36 hours after parturition (post partum). Unmated, age-matched (13 to 14-week-old) females served as controls. After the rats were decapitated, the thoracic aorta was rapidly removed and placed in cold Krebs solution. The aortic tube was freed from surrounding tissues and cut transversally to obtain rings 3 to 4 mm in axial length. Small hooks, made with 30-gauge needles, were carefully inserted into each ring to suspend them vertically in 15-ml glass-jacketed organ baths. The tissues were attached to isometric force-displacement transducers (FT-03, Grass Instruments, Quincy, Mass.) connected to a #7 Grass Polygraph. They were stretched to a passive tension of 2.0 gm, which, in preliminary experiments (Parent and St-Louis, unpublished data), was found to be optimal for aortic rings of both nonpregnant and pregnant rats. The Krebs solution used in these experiments contained in millimoles per liter: sodium chloride, 118; sodium bicarbonate, 25; potassium chloride, 4.7; calcium chloride, 2.5; magnesium sulfate, 1.18; potassium phosphate, 1.18; and dextrose, 5.5. The pH was 7.4 at 37° C, and the solution was bubbled with a mixture of 95% oxygen:5% carbon dioxide.

After 1 hour of equilibration, phenylephrine (1 μmol/L) was added to the bathing solution to measure tissue reactivity. At the plateau response of phenylephrine, the functional integrity of the endothelium was assessed by the application of acetylcholine (0.1 mmol/L). This response was quantified as the percent relaxation of phenylephrine-induced contraction (i.e., relaxation from the plateau response to phenylephrine). After full relaxation (45 to 50 minutes), the different experimental protocols were done. In the first protocol, we measured the response to acetylcholine, an endothelium-dependent vasorelaxant, in aortic rings of nonpregnant, pregnant, and post partum rats. A cumulative concentration-response curve to phenylephrine (1 nmol/L to 10 μmol/L) was charted for the tissues of each group of rats. The rings were then washed to remove phenylephrine by frequent changes in bathing fluid, and 75 to 90 minutes later a cumulative concentration-response curve to acetylcholine (10 nmol/L to 100 μmol/L) was obtained after precontracting rings with phenylephrine. The phenylephrine concentration used to precontract the tissues was 1.0 μmol/L, which produces an increase in tissue tension of about 80% to 90% of maximum response in rings of the different groups. A similar protocol was used for a second set of tissues, except that the curve to acetylcholine was replaced by a cumulative concentration-response curve to sodium nitroprusside (1 nmol/L to 10 μmol/L).

In a second protocol, a cumulative concentration-response curve to phenylephrine was first measured in the absence and then, on the same tissue, in the presence of N^G-monomethyl-L-arginine (0.10 mmol/L) or indomethacin (10 μmol/L) to block the influence of EDRF and of endogenous derivatives of arachidonic acid, respectively. Similar groups of rats were used (nonpregnant, pregnant, and post partum).

Each experimental concentration-response curve was analyzed as previously[7, 8] by microcomputer using the ALLFIT program to determine the concentration producing 50% of the maximum response and the maximum asymptote of the response. Statistical comparisons were made on the mean negative logarithm of the concentration producing 50% of the maximum response and mean maximum asymptote for each experimental group. Analysis of variance was performed, followed by the Dunnett test to compare each pregnant and post partum group with the nonpregnant controls. The paired *t* test was also performed to compare the concentration-response curve in the absence and in the presence of inhibitors in each experimental group. Analysis of variance with a two-factor mixed design and

repeated measure of one factor[13] were also used for the indomethacin and N^g-monomethyl-L-arginine results.

The agents used were L-phenylephrine hydrochloride and acetylcholine chloride obtained from Sigma Chemical Co. (St. Louis, Mo.), sodium nitroprusside from Fisher Scientific (Montreal Quebec), N^g-monomethyl-L-arginine monoacetate from Calbiochem Biochemicals (San Diego, Calif.), and indomethacin lactose from Merck Frosst (Pointe-Claire, Quebec).

Results

The effects of phenylephrine and acetylcholine on aortic rings from nonpregnant, pregnant, and post partum rats are reported in Fig. 1 and Table I. The responses to phenylephrine were markedly decreased in pregnant and post partum tissues, as shown by the rightward shift of their concentration-response curves in comparison with the controls (Fig. 1); the maximum responses were only slightly modified. These results, reported in Table I, show that the concentration elic-

iting 50% maximum response of phenylephrine was significantly ($p < 0.01$) increased by a factor of 2 and 2.6 in (ring of) pregnant and postpartum rats, respectively, compared with nonpregnant rats, whereas the maximum response was significantly ($p < 0.01$) decreased in pregnant and elevated in postpartum animals. The vasorelaxant responses to acetylcholine were similar in both groups of experimental tissues relative to nonpregnant rats, in terms of concentration producing 50% maximum response and maximum response.

Fig. 2 shows the results of an identical protocol with sodium nitroprusside, an endothelium-independent vasorelaxant. The responses to phenylephrine were again decreased in pregnant and post partum tissues in comparison with nonpregnant controls (Table II). The sensitivity of the vasorelaxant response to sodium nitroprusside was increased in tissues of post partum rats compared with their nonpregnant counterparts but not modified in the pregnant rats (Fig. 2, Table II). In contrast to acetylcholine, sodium nitroprusside fully re-

laxed the tissues from the precontracted level induced by 1.0 μmol/L phenylephrine. The maximum responses to sodium nitroprusside were identical in all groups of tissues and were not statistically different from 100% relaxation.

Fig. 3 shows the effect of 10 mol/L indomethacin on concentration-response curves to phenylephrine. We have previously observed, by mass spectroscopy coupled to gas chromatography, that this concentration of indomethacin (10 μmol/L) totally inhibited the output of prostaglandin material in experimental conditions similar to the ones used here (Falardeau and St-Louis, unpublished data). In the present experiments, indomethacin decreased the responsiveness of nonpregnant and post partum aortic rings to phenylephrine (Fig. 3, *left* and *right panels*, respectively), as illustrated by the rightward shift of the concentration-response curves and the depression of the maximum response in post partum rats. On the other hand, it did not substantially affect the response to phenylephrine in tissues from pregnant rats (Fig. 3, *middle panel*). Significant decreases in the negative logarithm of the concentration required for 50% maximum response were observed in tissues of all groups (Table III), but the magnitude of this effect was much less in pregnant rats. The maximum responses were decreased in nonpregnant and postpartum tissues ($p < 0.001$), suggesting that an arachidonic acid derivative was secreted on stimulation with phenylephrine and that it exerted contractile properties on the aortic rings.

In a similar protocol we tested the blockade of EDRF liberation by N^g-monomethyl-L-arginine. Fig. 4 shows that N^g-monomethyl-L-arginine (0.1 mmol/L) substantially increased the responses of the aortic rings in the three groups of animals. This concentration of N^g-monomethyl-L-arginine (0.1 mmol/L) was shown to almost totally abolish the vasorelaxant response to carbachol in phenylephrine-precontracted aortic rings of the rat (St-Louis and Sicotte, preliminary experiments). This was manifested by both an augmented potency (leftward shift of the concentration-response curves) and increased maximum responses. These effects were highly significant (Table IV) for the three groups of tissues, but the increase in potency was of a smaller magnitude in pregnant animals than in nonpregnant and post partum rats, whereas the enhancement of the maximum response was similar in all three tissue types. This is demonstrated by smaller increases in the negative logarithm of the concentration producing 50% maximum response values in pregnant than in nonpregnant and post partum tissues, which are respectively 0.39 ± 0.04, 0.80 ± 0.09, and 1.05 ± 0.10 units of the negative logarithm of the concentration producing 50% maximum response (all $p < 0.001$). These observations suggest that, in intact aortic rings of the rat, the effect of phenylephrine is

hindered by an endogenous factor whose secretion is blocked by N^g-monomethyl-L-arginine, and although present during pregnancy, this physiologic antagonism seems to have a lesser influence in this situation.

Finally, as EDRF markedly affected the responses of aortic tissues to phenylephrine and could mask the possible influence of prostaglandins on the vascular reactivity to phenylephrine, we tested indomethacin on aortic rings in which EDRF liberation was already blocked. Fig. 5 shows that, in comparison to N^g-monomethyl-L-arginine (0.1 mmol/L) alone *(closed circle)*, when the same aortic rings were under the influence of both N^g-monomethyl-L-arginine (0.1 mmol/L) and indomethacin (10 μmol/L) *(open circle)*, the effect of phenylephrine was not modified. The only significant change observed was a small decrease of maximum response in tissues of pregnant rats by comparison with nonpregnant ones (respectively, 2.57 ± 0.08 vs 2.81 ± 0.06, $p < 0.05$ in the presence of N^g-monomethyl-L-arginine, and 2.49 ± 0.08 vs 2.86 ± 0.06, $p < 0.05$ in the presence of N^g-monomethyl-L-arginine and indomethacin). These results suggest that the liberation of a vasodilating derivative of arachidonic acid through cyclooxygenase does not influence the responses of nonpregnant, pregnant, and post partum aortic rings to phenylephrine.

Comment

In the present study, we investigated one of the possible mechanisms that could be responsible for the blunted response to vasoconstrictors during pregnancy in the rat. The mechanisms proposed during the last few years[15, 17] are (1) autoregulation of receptors for vasoactive agents, (2) increased endogenous liberation of vasodilator agent(s) by the administration of vasoconstrictors, (3) regulation of postreceptor coupling mechanism, and (4) modification of the mechanical properties of the vessel wall. Very recently, Blizard and

Fig. 4. Folk[18] have proposed that the late gestational decrease in blood pressure in the rat is the result of combined metabolic requirements of maternal and fetoplacental tissues on maternal hemodynamics. This hypothesis, although logically presented and very attractive, remains silent on the pathway mechanisms linking both phenomena. In those experiments we have verified the involvement of the second mechanism proposed above.

The involvement of an increased endogenous influence of vasodilator substance(s) in the blunted response to vasoconstrictors during pregnancy was proposed several years ago[19] and received much attention up to now, but the results obtained have been controversial.[12, 13] The discovery of EDRF[1] furnished an interesting alternative to arachidonic acid derivatives as the putative endogenous agent.

We have observed that the overall reactivity of aortic rings to an endothelium-dependent vasorelaxant such acetylcholine is not modified in tissues from term pregnant and early post partum rats in comparison with nonpregnant controls, although the effects of phenylephrine are decreased in sensitivity under these conditions (Fig. 1). This is in agreement with the results of Teeuw and DeJong,[20] who have shown that the vasodepressor action of acetylcholine on blood pressure is similar in virgin and term pregnant rats. This is also in agreement with recent results obtained in our laboratory,[15] where we have observed that the endothelial lining of the superior mesenteric artery of nonpregnant and pregnant rats similarly influences the responses to adrenergic agents. Weiner et al.[21] reported increased response and efficacy of uterine and carotid artery segments to acetylcholine during pregnancy in the guinea pig. These results were obtained in a protocol similar to ours, except that these authors precontracted their tissues to a lower level of contraction. This has induced a much lower level of contraction, which could be responsible for the higher potency of acetylcholine to relax vessel segments.[22]

EDRF, the tissue mediator of the vasorelaxant effects of acetylcholine and recently proposed to be nitric oxide,[4] activates soluble guanylate cyclase in smooth muscle cells. This vasorelaxant mechanism is shared by nitro vasodilators such as sodium nitroprusside. The action of the latter on aortic rings from pregnant rats is not modified, as reported in the perfused mesenteric vascular bed in vitro.[23] This indicates that the stimulation-relaxation coupling mechanisms for this kind of agents are not altered during pregnancy, at least in such a way as to be responsible for the blunted response to vasoconstrictors. The same is probably true for tissues from post partum rats, although our results (Fig. 2) are consistent with an increase in sensitivity to sodium nitroprusside. This effect may be the consequence of a much lower sensitivity of this group of aortic rings to phenylephrine, resulting in a smaller response (in

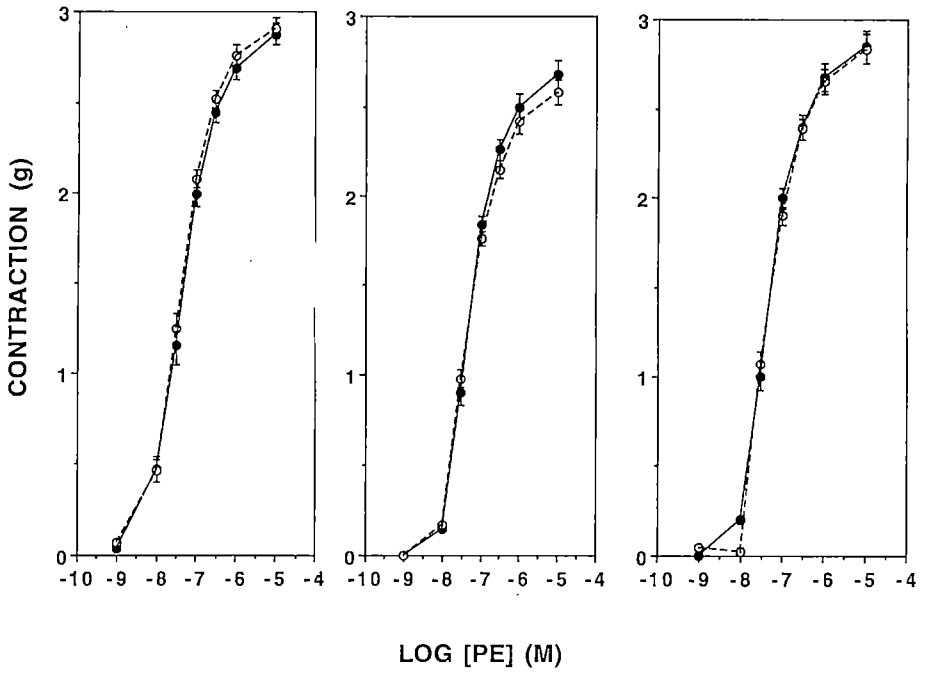

Fig. 5. Concentration-response curves to phenylephrine in the absence *(filled circles)* and presence *(open circles)* of indomethacin (10 μmol/L) in N^g-monomethyl-L-arginine–treated (0.1 mmol/L) aortic rings of nonpregnant *(left)*, pregnant *(middle)*, and post partum *(right)* rats. Symbols and bars represent means ± SE of number of 24 measurements. Abscissa indicates molar concentration of phenylephrine in logarithm and ordinate, contractile responses in grams.

terms of percent maximum response) to 1.0 μmol/L phenylephrine used to precontract the tissues. We have previously demonstrated for atrial natriuretic peptide that a lower level of precontraction on aortic strips results in a significant leftward shift of the vasorelaxant concentration-response curve of this peptide.[22]

The results contained in the present report on the use of N^g-monomethyl-L-arginine also suggest the noninvolvement of EDRF in the resistance to α-adrenergic vasoconstriction during pregnancy. N^g-monomethyl-L-arginine is believed to block the formation of EDRF from tissue L-arginine at the enzyme level.[4] When used to influence the concentration-response curve to phenylephrine (Fig. 4), we observed a substantial increase in overall reactivity to phenylephrine in the three groups of tissues. This is in agreement with our earlier report on superior mesenteric artery rings,[15] in which we showed that the sensitivity of these tissues to phenylephrine and norepinephrine was inversely related to the relative presence of functional endothelium and that of isoproterenol was directly related to it. For the three agents, the just-mentioned relationship was similar in magnitude in tissues from nonpregnant and pregnant rats. This is also in agreement with the results of Umans et al.[24] They reported that bolus intravenous injections of N^g-monomethyl-L-arginine produced similar increases in blood pressure and decreases in heart rate in conscious, instrumented virgin and term pregnant rats. Surprisingly, Jansakul et al.[25] observed a supersensitivity to α-adrenergic agonists on aortic rings at the terminal stage of pregnancy in the rat. This supersensitivity, or more exactly "superresponsiveness," is the opposite of what has been observed many times,[7-9, 15] e.g., a decreased sensitivity to α-adrenergic agents (increased in the concentration producing 50% maximum response) was consistently reported. These authors[25] reported, however, that the removal of endothelium or the presence of oxyhemoglobin significantly increased the response to α-adrenergic agonists as we have reported here.[15] They also showed that the vasorelaxant response to acetylcholine in norepinephrine or phenylephrine-precontracted aortic segments was not modified during pregnancy. This last part is totally in agreement with the results presented here. This is also in agreement with our previous results, which showed a difference of about one log unit on the 50% maximum response between the sensitivity of tissues to phenylephrine with and without a functional endothelium.[15] Furthermore, we must consider that vascular tissue strips, such as aorta, female artery, etc., in which the endothelium has been removed by the preparation procedure are less sensitive to vasoconstrictors when obtained from pregnant animals.[7, 8]

In the present experiments, however, our data suggest that the endothelium has much less influence during pregnancy than in nonpregnant and post partum

periods (Table IV). This is demonstrated by the smaller increases in the log of the concentration producing 50% maximum response values in pregnant than in nonpregnant and post partum tissues. On the contrary, Ahokas et al.[26] recently present an abstract showing an increased blood pressure response to N^g-monomethyl-L-arginine in pregnant spontaneously hypertensive rats, but not in the Wistar-Kyoto normotensive ones.

The data obtained with indomethacin are, however, puzzling. Indeed, in Fig. 3 an inhibition of the contractile response to phenylephrine was observed after the incubation of aortic rings with indomethacin. This is the opposite of what can be expected from the original hypothesis, e.g., of a vasodilator arachidonic acid derivative being responsible for the blunted response to vasoconstrictors. Our results rather indicate that phenylephrine induces the endogenous secretion of a vasoconstrictor factor that helps to contract the tissues. Alternatively, under the influence of indomethacin, the effect of another agent, perhaps through the lipoxygenase pathway, may be unraveled. This last explanation is unlikely because in preliminary experiments we have observed that no such compound is produced by aortic tissue in vitro, in the absence or presence of the same concentration of indomethacin (Falardeau and St-Louis, unpublished data). These explanations are quite speculative at present, however, since the small inhibition with indomethacin does not occur in the presence of N^g-monomethyl-L-arginine (Fig. 5). This observation remains to be fully investigated.

In conclusion, the present results do not support the involvement of arachidonic acid derivatives, by the cyclooxygenase pathway, or of EDRF in the decreased sensitivity to α-adrenergic vasoconstrictors in pregnant and postpartum rats. They also suggest that endogenous EDRF liberation by the vascular wall on the action of vasoconstrictors is much less significant in pregnant than in virgin and postpartum rats. Furthermore, indomethacin is believed to block an endogenous mechanism, helping the action of phenylephrine in aortic rings of the rat, especially in the postpartum period.

Inhibition of preimplantation mouse embryo development by isoflurane

Joe R. Warren, PhD,[a] Barry Shaw, MD,[b] and Michael P. Steinkampf, MD[a]
Birmingham, Alabama

OBJECTIVE: Preimplantation mouse embryos were exposed to a commonly used inhalational anesthetic agent, isoflurane, to determine its effects on embryo development.
STUDY DESIGN: Two-cell embryos were exposed at various intervals (5 to 6 hours, 3 to 4 hours, and 0 to 1 hour) before the onset of their first cleavage in vitro. In addition, the effects of 5% isoflurane on four-cell embryos exposed about 2 hours after the first cleavage and morula stage embryos also were examined.
RESULTS: Development to the blastocyst stage was inhibited by 3% and 5% isoflurane ($p < 0.005$) but not by 1.5% isoflurane when two-cell embryos were exposed 3 to 4 hours or 0 to 1 hour before the onset of cleavage. Most of the affected embryos completed cell division and came to a halt at the three- to four-cell stage. The development of embryos exposed to isoflurane at the four-cell or morula stage was unaffected.
CONCLUSIONS: Isoflurane adversely affects subsequent preimplantation development when two-cell mouse embryos are exposed just before the onset of their first cleavage in vitro. (AM J OBSTET GYNECOL 1992;166:693-8.)

Key words: Cleavage, mouse, embryo, isoflurane, anesthesia

An estimated 50,000 pregnant women are exposed to general anesthesia during surgery each year in the United States. In some patients, the operation is performed before the detection of pregnancy; in others, it is necessary in spite of, or because of, a patient's pregnancy. Exposure of operating room personnel to trace concentrations of waste gases may represent another mechanism of anesthetic exposure in pregnancy.[1] This occupational exposure has been suggested to be responsible for a higher incidence of spontaneous abortions among operating room personnel than among various control populations[2] and for a possible increase in the incidence of infertility in female anesthesiologists.[3]

One recently introduced inhalational anesthetic that is widely used is isoflurane (1-chloro-2,2,2-trifluoroethyl difluoromethyl ether). Isoflurane's low blood solubility and limited extent of metabolism allows rapid induction of anesthesia and prompt clearance from the body after surgery, minimizing the risk of accumulation of toxic metabolites.[4] Data on the outcome of offspring of women exposed to isoflurane during pregnancy is limited.[5] Although no teratogenic effects have been observed in rabbits and rats,[6, 7] increased frequencies of cleft palate, skeletal variations, and fetal growth retardation were observed in pregnant mice exposed to light anesthetic doses of isoflurane.[8] The manufacturer of the anesthetic has reported an increase in the incidence of fetal resorption in pregnant mice exposed to isoflurane at six times the clinical dose used in humans.[9] Little is known about the effect of isoflurane on embryo development before implantation. A preliminary study by Chetkowski and Nass[10] indicated that isoflurane inhibited the development of preimplantation mouse embryos cultured in vitro, whereas nitrous oxide exposure was without effect. In contrast, we recently determined that nitrous oxide also may inhibit mouse embryo cleavage, with the effect being highly dependent on the stage of embryo development.[5] These findings may be of considerable importance in clinical medicine. While general anesthesia is not routinely used for embryo transfer in the United States, anesthesia for transcervical embryo transfer is often used in Great Britain,[11] and transfer of embryos to the fallopian tubes, a procedure in which general anesthesia is widely used, is becoming an increasingly accepted treatment for infertility.[12] The purpose of the present study was to determine the effect of isoflurane on mouse embryos at various times during preimplantation development.

Material and methods

Guidelines approved by the University of Alabama at Birmingham Animal Resources Program for the care and use of animals were followed for these experiments. CB6F1/J female mice (Jackson Laboratory, Bar Harbor, Me.), maintained on 12-hour light/dark cycles, were injected intraperitoneally between 4:00 PM and 10:00 PM with 10 IU pregnant mare's serum gonado-

tropin (Organon, Inc., via Diosynth, Inc., Chicago, Ill.) to stimulate follicle development and 48 hours later with 20 to 30 IU of human chorionic gonadotropin (Organon) to initiate ovulation.[13] After this second injection, the females were caged with C57BL/10J males overnight and examined for vaginal plugs the following morning as evidence that mating had occurred. Mated females were killed by cervical dislocation 40 to 44 hours after the human chorionic gonadotropin injection, and their oviducts were removed and transferred to four-well culture dishes. Biggers, Whitten, and Whittingham medium[14] prepared from its individual components in double distilled water and then filtered through 0.22 μm membranes (Millipore, Bedford, Mass.), supplemented with 0.3% bovine serum albumin (Fraction V, Sigma Chemical Co., St. Louis, Mo.), was used for all embryo cultures. Two-cell embryos were flushed from the oviducts with culture medium bovine serum albumin with a blunt, 30-gauge needle. Except for the time during which they were exposed to isoflurane or air (controls), the embryos were maintained in 5% carbon dioxide in air at 37° C.

Exposure of the preimplantation embryos in vitro was accomplished in a plastic, 2 L chamber that was warmed to 37° C in a dry incubator. This chamber was connected to an anesthetic machine set to deliver a total air flow rate of 2.5 L/min. Culture medium was preequilibrated in this chamber for 30 to 60 minutes before the time of exposure, at which time the embryos were transferred to the preequilibrated medium and incubated in the exposure chamber for 30 minutes. Controls were transferred to medium that was preequilibrated in room air at 37° C. No appreciable evaporation of the culture media during the incubation period was detected, as determined by measurement of fluid volumes before and after incubation. After 30 minutes, both exposed and control embryos were transferred back to culture medium in 5% carbon dioxide in air at 37° C and monitored for cleavage and development.

Since induction and maintenance of anesthesia usually require a concentration of 1.5% to 3%,[9] two-cell embryos were exposed to 1.5%, 3%, and 5% isoflurane at intervals approximately 5 to 6 hours, 3 to 4 hours, and 0 to 1 hour before the expected onset of cleavage at approximately 12:00 PM to 1:00 AM on the morning after the embryos were collected (data not shown). Usually several embryos had already cleaved before the final exposure. These embryos were removed from these experiments or treated as four-cell embryos. Four-cell embryos were treated only with 5% isoflurane within 2 hours after cleavage, and morula stage embryos were treated with 5% isoflurane before blastocoel formation.

Development of the embryos was observed periodically and compared with the development of the controls. Embryos were classified as two-cell, three- to four-cell, five- to eight-cell, morula stage, and blastocyst stage embryos for purposes of monitoring in vitro cleavage. Abnormal morphology at any stage was noted. The percentage of embryos to cleave to the blastocyst stage after 72 hours of culture was determined.

Experiments were performed at least three times to ensure reproducibility, with between 30 and 51 total embryos used for each condition (Table I). For each experiment embryos collected from mice were pooled and then randomly assigned to an experimental condition. Separate control groups were used for each anesthetic concentration tested at each time point to minimize any possible variation in embryo quality among different experiments. Comparisons between treated and control groups of embryos were performed with χ^2 analysis.

Results

When two-cell embryos were exposed to 5% isoflurane before the onset of cleavage in vitro, significant effects were observed (Fig. 1). Whereas 75.6% of embryos exposed 5 to 6 hours before onset developed into blastocysts compared with 86.1% for the controls, only 19.5% and 35% of those exposed 3 to 4 hours and 0 to 1 hour before onset, respectively, developed to that stage, compared with 75% ($p < 0.005$) and 68.6% ($p < 0.025$) for the controls. Among the embryos that continued to develop in the treated groups, an increase in cell fragmentation was apparent, and blastocoel size was observed to be smaller than in the control groups (Fig. 2).

Similar effects were observed when embryos were treated with 3% isoflurane. In those exposed 3 to 4 hours before onset, only 36.4% developed into blastocysts, compared with 77.2% for the controls

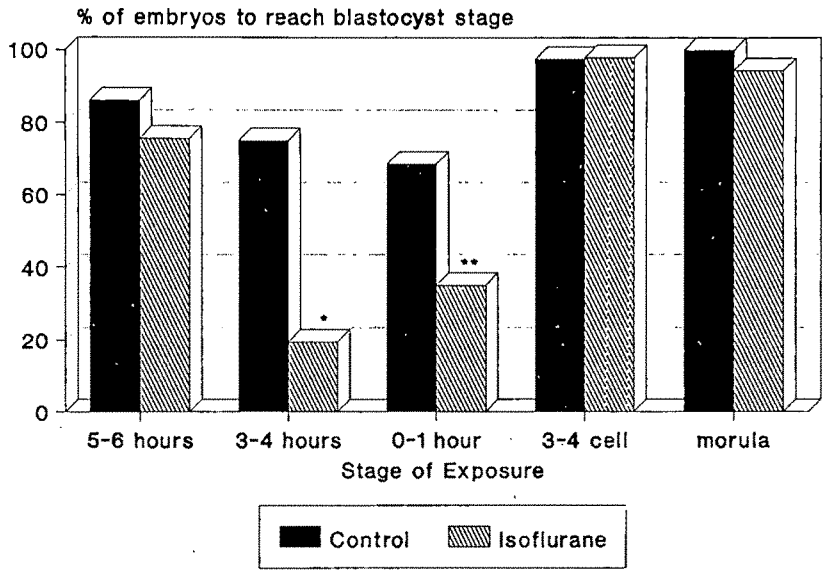

Fig. 1. Developmental outcome of embryos exposed in vitro to 5% isoflurane for 30 minutes at various times in relation to expected onset of the first cleavage in vitro. *Asterisk*, $p < 0.005$; *double asterisk*, $p < 0.025$.

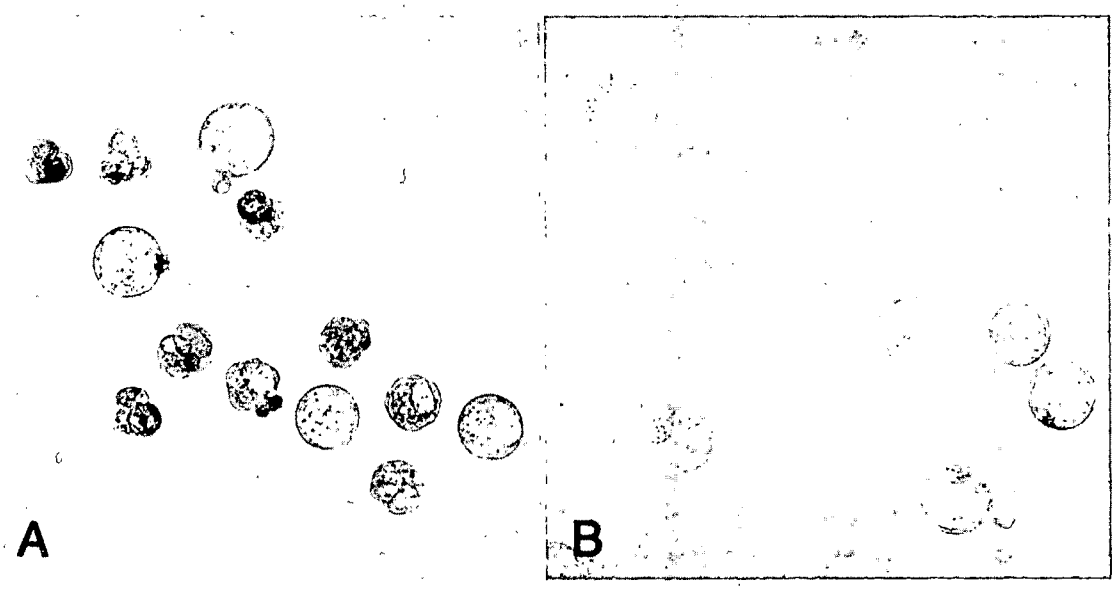

Fig. 2. Preimplantation development of mouse embryos after 30 minutes' exposure in vitro to 5% isoflurane **(A)** or air **(B)** at 3 to 4 hours before onset of first cleavage in vitro. Note halt of development at earlier stages and smaller blastocoel cavities in treated group. (Original magnification ×150.)

($p < 0.005$), whereas in those exposed 0 to 1 hour before onset, 31.7% developed, compared with 87.2% for the controls ($p < 0.005$) (Fig. 3). These effects were not observed when the exposure level was reduced to 1.5% (data not shown). Even when embryos were exposed 0 to 1 hour before the onset of cleavage, 79.2% of treated embryos developed into blastocysts, compared with 79.5% of the controls. No effects on subsequent development were observed when four-cell and morula-stage embryos were treated with 5% isoflurane (Fig. 1).

In those groups in which development to the blastocyst stage was affected by isoflurane, periodic assessment of the extent of cleavage was undertaken to determine the point at which development was halted. Of the two-cell embryos exposed to 5% isoflurane 0 to 1 hour before onset, 85% cleaved to the three- to four-cell stage, but only 52.5% continued to the five- to eight-

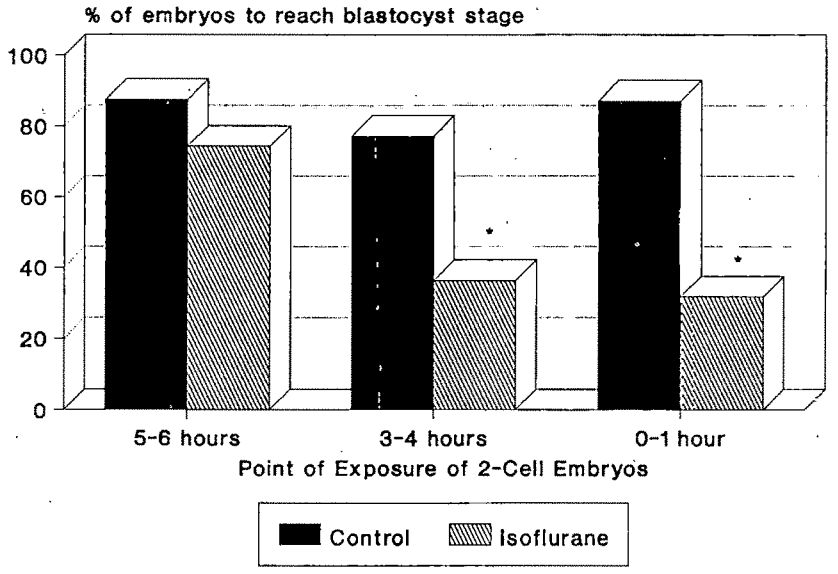

Fig. 3. Developmental outcome of embryos exposed in vitro to 3% isoflurane for 30 minutes at various times in relation to expected onset of the first cleavage in vitro. *Asterisk*, $p < 0.005$.

cell stage (Fig. 4). In those exposed to 3% at approximately the same time point, 80.5% cleaved to the three- to four-cell stage, but only 41.5% continued developing (Fig. 5). In general, the proportion of treated embryos to undergo the first in vitro cleavage was comparable to that of the control group, with the deleterious effect of isoflurane on embryo development becoming more apparent as the posttreatment incubation progressed.

Comment

In this study, isoflurane was shown to affect the development of preimplantation mouse embryos exposed at the late two-cell stage. When two-cell embryos were exposed to 3% and 5% isoflurane within 3 to 4 hours before the onset of cleavage, the development in a significant number of embryos was halted after the first cleavage in vitro. However, the subsequent cleavage of four-cell embryos exposed within 2 hours after this first cleavage was not affected by isoflurane exposure. Because approximately 90% of two-cell embryos normally progress to the four-cell stage, differences in embryo quality between different developmental stages would not explain these results. We feel that the effects are probably due to differences in sensitivity at various points within the cell cycle.

Cytotoxic agents prevent cell division from occurring in actively dividing cells by disrupting key metabolic functions, energy metabolism, or the mitotic spindle. For example, aphidicolin, which inhibits deoxyribonucleic acid (DNA) synthesis by specifically inhibiting DNA polymerase-α,[15] and cycloheximide, which primarily inhibits protein synthesis[16]; both inhibit cell proliferation. Other agents such as colchicine, which binds to tubulin, inhibit polymerization of the mitotic spindle and thus block mitosis without directly affecting cell metabolism.[17] The cytotoxic effects of anesthetic agents were first recognized in 1878, when Bernard reported that ether vapors retarded the growth of plant seedlings.[18] Some anesthetic agents apparently interrupt mitosis by arresting cells in metaphase, possibly by the reversible dispersal of labile microtubules and depolymerization of the mitotic spindle during M phase.[19] Inhibition of DNA synthesis during the S phase,[20] interference with prometaphase movement,[21] and prolongation of the G_2 postsynthetic phase[22] have also been suggested to be associated with various anesthetic agents. Thus the effects of isoflurane observed in this study could be caused by a variety of specific actions alone or in combination.

Unlike most other cell types, in which cell mass doubles before cleavage, preimplantation embryos undergo reductive cleavage and require relatively little preparation for cytokinesis (cytoplasmic division). For this reason, most energy expenditure and synthetic activity is directed toward DNA synthesis and mitosis. DNA replication (S phase) lasts 6 to 7 hours, whereas the G_1 phase, if it exists at all, appears to last only 1 to 2 hours. The G_2 phase, which lasts 12 to 15 hours in two-cell embryos, is reduced sharply in subsequent cycles.[23] The results of the present study suggest that the effect of isoflurane may be limited to the late G_2 or M phases in mouse preimplantation embryos. It is possible that the increased cell-cycle asynchronicity that occurs with continued preimplantation embryo cleavage limits the deleterious effect of isoflurane exposure at later stages of development.

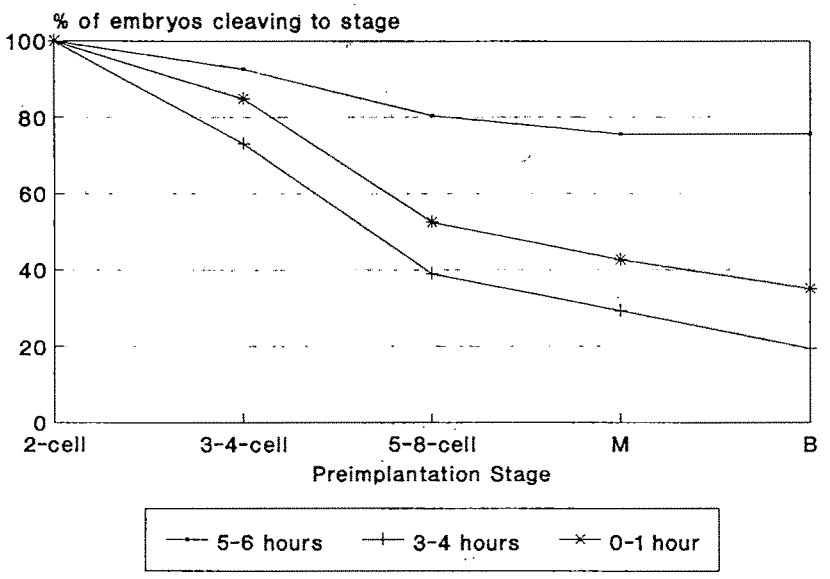

Fig. 4. Cleavage of embryos after exposure to 5% isoflurane at various times before expected onset of first cleavage in vitro.

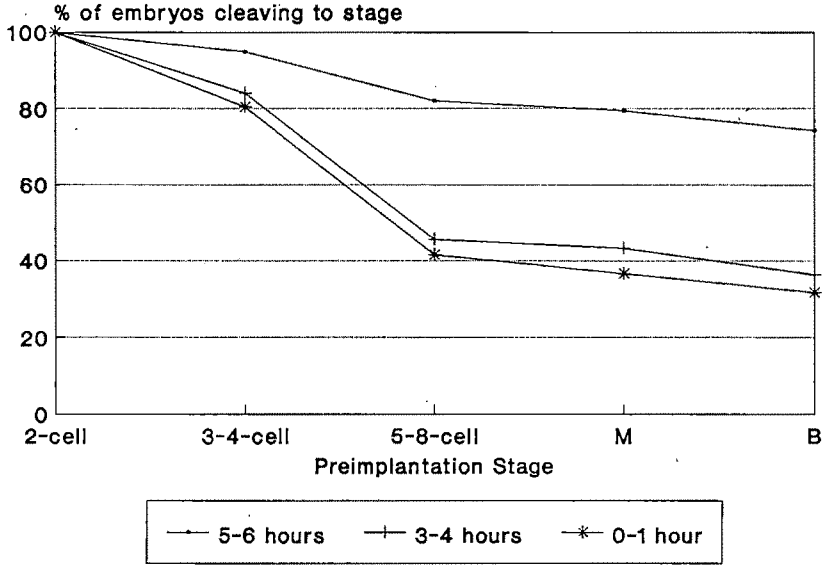

Fig. 5. Cleavage of embryos after exposure to 3% isoflurane at various times before expected onset of first cleavage in vitro.

We previously have reported that nitrous oxide exhibits a comparable cytotoxic effect in two-cell mouse embryos exposed just before cleavage.[5] However, in contrast to the effect of isoflurane, nitrous oxide treatment significantly inhibited any subsequent cell division, whereas the effect of isoflurane exposure did not become apparent until after the first in vitro cleavage. This suggests that these two anesthetic agents may exert their effects through different mechanisms. Further studies will be needed to characterize the nature of these effects.

The results of this and our previous study[5] demonstrate that the effects of anesthetics on preimplantation embryo cleavage vary markedly with stage of development and point of exposure of the embryos. The findings of previous studies indicating the absence of deleterious effects of nitrous oxide exposure may have been due to exposure before fertilization[24] or failure to rigorously control for the timing of the developmental stages at which embryos were exposed.[10] In contrast to Chetkowski and Nass,[10] we were unable to demonstrate an effect of isoflurane at a concentration of 1.5%.

Whether this was due to differences between the embryos of different mouse strains, differences in the anesthetic mixture, or some other reason is unclear. In their studies, embryos were exposed to anesthetics in phosphate-buffered saline and then transferred to Ham's F-10 medium (without protein supplementation), whereas our experiments used Biggers, Whitten, and Whittingham medium with bovine serum albumin throughout the exposure and culture period. Differences in electrolyte concentrations in solutions of equal osmolarity have only minor effects on the solubility of isoflurane,[25] and thus it is unlikely that media composition per se would account for the observed differences. The 30-minute incubation of the bicarbonate-based culture medium solution in air/isoflurane could cause a significant fall in pH, but one would expect that any pH changes due to decreased carbon dioxide levels in the media during exposure would have affected the treated and control groups equally. However, we have previously noted a beneficial effect of bovine serum albumin on mouse embryo survival, and it is possible that the more favorable culture conditions in our study might have attenuated the deleterious effect of isoflurane. Also, albumin has been reported to interact with halogenated anesthetics,[26] and an effect of protein supplementation on the bioavailability of isoflurane cannot be ruled out. Nevertheless, the concentration of isoflurane at which we noted significant effects is within the range used in human anesthesia.[9] Interestingly, Fishel et al.[11] suggested that the choice of anesthesia for transfer of cleaving human embryos could be a factor in in vitro fertilization pregnancy rates. We suggest that caution be exercised with respect to the choice of anesthesia for clinical procedures involving the transfer of cleaving embryos.

We thank Dr. William Helm and Dr. C. Richard Parker, Jr., for their critical review of this manuscript.

Venous drainage of the human uterus: Respiratory gas studies in normal and fetal growth-retarded pregnancies

Giorgio Pardi, MD,[a] Irene Cetin, MD,[a] Anna Maria Marconi, MD,[a] Patrizia Bozzetti, MD,[a] Mauro Buscaglia, MD,[a] Edgar L. Makowski, MD,[b] and Frederick C. Battaglia, MD[b]

Milan, Italy, and Denver, Colorado

OBJECTIVE: To determine respiratory gas relationships between the uterine veins and umbilical vein in normal and pregnancies complicated by intrauterine growth retardation.

STUDY DESIGN: Respiratory gases were measured in both uterine veins and the umbilical vein in eight normal and 13 pregnancies with intrauterine growth retardation.

RESULTS: No significant differences were found in the placental versus nonplacental uterine veins. There was a significant correlation for umbilical and uterine venous values of Po_2 ($p < 0.002$) and Pco_2 ($p < 0.004$) in appropriate-for-gestational-age pregnancies, umbilical venous Po_2 was always less than uterine venous Po_2, and Pco_2 always greater than uterine. The transplacental gradient was significantly higher in intrauterine growth retarded than appropriate-for-gestational-age pregnancies for both Po_2 and Pco_2. There was a lower uterine oxygen extraction in intrauterine growth retarded pregnancies ($p < 0.05$).

CONCLUSION: There is no consistent relationship between placental venous drainage in each uterine vein and placental location. The human placenta simulates a relatively inefficient venous equilibrator and the larger transplacental gradients in intrauterine growth retarded pregnancies may reflect differences in both perfusion pattern and placental structure. (Am J Obstet Gynecol 1992;166:699-706.)

Key words: Respiratory gases, uterine venous drainage, pregnant uterus, transplacental gradient, intrauterine growth retardation

The physiologic characteristics of the venous drainage of the human uterus are not well known, e.g., the proportion of the total venous drainage of the uterus representing drainage of the placenta versus myometrial and endometrial drainage has yet to be defined. In addition, it is not known whether the proportion of placental to nonplacental venous drainage in each uterine vein differs as a function of placental location. To study uterine metabolism in man, it is essential to obtain venous samples representative of the mixed placental and nonplacental drainage. In sheep carrying single fetuses with placental cotyledons in both uterine horns, venous samples drawn simultaneously from the right and the left uterine veins have virtually identical composition and thus either uterine vein may be sampled for determination of substrate fluxes.[1] Conversely, a remarkable variability in the venous drainage of the pregnant uterus has been demonstrated in the pregnant monkey, with large and unequal arteriovenous differences in the two veins.[2, 3] The effect of placental location on uterine artery velocimetry has been studied in human pregnancies, and reduced vascular resistance has been reported for the uterine artery ipsilateral to the placenta.[4] These findings suggest that there may be consistent differences in respiratory gas concentrations between the right and left sides of the uterine venous drainage as function of placental location.

The study of the respiratory gas pattern of the venous drainage of the human uterus is also important in providing insight into the perfusion pattern of the human placental circulation. In species with a hemochorial, labyrinthine placenta, such as guinea pigs[5] and rabbits,[6] the maternal and fetal placental circulations simulate a countercurrent exchange system. The horse, which has a diffuse epitheliochorial placenta, also functions as a countercurrent exchanger.[7] In other mammals with an epitheliochorial placenta, such as the sheep, the two circulations form an exchange system, which has been called a "venous equilibrator," with a low degree of effectiveness.[8, 9]

The effectiveness of the human placenta has not been clearly defined. However, previous studies on placental oxygen transfer have suggested that the venous equilibration model may be applicable to the human placenta.[10, 11]

respiratory gas concentrations in both uterine veins in relation to placental location; (2) compare uterine venous gas tensions with those obtained from the umbilical vein at delivery, to evaluate the perfusion characteristics of the placental circulation (i.e., venous equilibrator vs countercurrent exchanger); and (3) determine whether pregnancies complicated by fetal growth retardation present differences in uterine venous respiratory gas concentrations consistent with changes in uterine perfusion relative to the metabolic demands of the conceptus.

Patients and methods

Informed consent was obtained from all patients, and the procedures were approved by the Institute Board of the Department of Obstetrics and Gynecology of the University of Milan, which has the responsibility for the evaluation of all clinical studies.

Clinical studies. Twenty-one patients undergoing elective cesarean section were studied at 35 to 40 weeks' gestation. Gestational age was calculated from the last menstrual period and confirmed by serial ultrasonographic examinations. Eight of these pregnancies were normal, terminating in the delivery of fetuses whose birth weights were appropriate for gestational age (AGA) using standards developed for the Italian population.[12] The indications for cesarean section in these patients were either repeat cesarean section or breech presentation. Thirteen pregnancies were complicated by intrauterine fetal growth retardation (IUGR), and fetuses were small for gestational age at birth. IUGR was determined by serial ultrasonographic measurements and confirmed at birth by fetal birth weights <2nd percentile according to Italian Standards.[12] Cesarean sections were performed with the patients in the left lateral decubitus position after an overnight fast. Intravenous thiopental sodium was used for induction of anesthesia, and general anesthesia was maintained by ventilation with a concentration of 60% nitrous oxide and 40% oxygen. Blood pressure was carefully monitored and no episodes of significant hypotension were detected. The placental location was determined by ultrasonography before the beginning of the surgical procedure. In the 21 patients studied, the placenta was lateral in 19 cases and central in two cases.

To sample the uterine veins, the vesicouterine serosa was incised and the bladder gently separated by finger dissection from the underlying uterine wall. The main branches of the uterine venous plexuses were visualized. Both right and left uterine veins were sampled with a 25-gauge needle connected to a heparinized syringe immediately before the transverse uterine incision of the inferior segment. The time interval from induction of anesthesia to uterine venous sampling was <5 minutes in all cases. At the same time, arterial blood was sampled from the maternal radial artery. The additional time required for the entire procedure of preparing the veins and sampling the blood was never >1 minute. No complications were observed during and after surgery. Umbilical venous and arterial blood samples were withdrawn from a doubly clamped segment of the cord immediately after fetal extraction.

Analytic procedures. Blood samples were treated as anaerobically as possible and kept on ice until analyses were completed, usually within 10 minutes. pH, P_{O_2}, and P_{CO_2} were measured with an ABL 330 Radiometer (Denmark). Hemoglobin concentration and oxygen saturation were measured in duplicate with a Radiometer OSM_2 Analyzer. As a check on the validity of the anaerobic collection of blood samples, in vivo dissociation curves were constructed for both the fetal and maternal data in all patients.

Calculations. Oxygen content was calculated according to the equation

$$O_2 \text{ cont (mmol/L)} = \text{hemoglobin (gm/L)} \times \text{oxygen saturation} \times 0.05982 \text{ (mmol/gm)}$$

and the percent of uterine oxygen extraction was calculated as

$$\text{Percent } O_2 \text{ extr} = [(A\text{-}V)\ O_2 \text{ cont (mmol/L)} / (A)\ O_2 \text{ cont (mmol/L)} \times 100$$

where *O_2 cont* is oxygen content, *O_2 extr* is oxygen extraction, *A* is maternal radial artery, and *V* is right and left uterine veins.

Statistics. Paired Student *t* test was used to calculate the significance of the difference between placental and nonplacental uterine veins (Table I). Comparison between values obtained in AGA and IUGR pregnancies were made with Mann-Whitney tests (Table II). Regression analyses were done by the least-squared method. Data were expressed as mean ± SEM.

Results

The data from 21 patients (13 IUGR and eight AGA) were used for the analysis below. The clinical data for all these patients are summarized in Table III.

Placental and nonplacental uterine oxygenation. Table I presents P_{O_2}, P_{CO_2}, oxygen saturation, oxygen content, and percent uterine oxygen extraction in the placental and nonplacental uterine veins of both AGA and IUGR pregnancies. No significant differences were observed between placental and nonplacental values for all parameters studied. Note that the average values reported in Table I refer only to those pregnancies that presented a lateral (right or left) placental localization by ultrasongraphy. Central placental pregnancies are omitted (two IUGR pregnancies).

Fig. 1 presents the relationship between placental and nonplacental uterine venous oxygen saturations

with an identity line shown for comparison. Note that there were no systematic differences between placental and nonplacental values; the data were characterized by a great variability among patients for the placental-nonplacental differences. A similar relationship between placental and nonplacental values was found for the other parameters under study. There were no variables measured in which there were systematic differences between placental and nonplacental values.

Uterine-umbilical respiratory gas exchange. To better understand the relationship between the umbilical and uterine venous samples for respiratory gases, the data were analyzed in two different ways. First, to obtain an estimate of mixed uterine venous drainage, the mean of the placental and nonplacental uterine venous values was calculated and used to study the relationship between uterine venous and umbilical venous values. Second, the data were analyzed using the uterine venous values that were least oxygenated in each case, regardless of the anatomic location of the placenta. The reason for this is that such an analysis provides a minimal estimate of the P_{O_2} and P_{CO_2} gradients between the two streams. Such an analysis would tend to maximize an estimate of the efficiency of the human placenta. Figs. 2 and 3 present the data for both AGA and IUGR patients. There were no significant relationships in the IUGR patients; however, there were highly significant relationships for the normal pregnancies. The regression analyses are presented in the legends. Note that the mean P_{O_2} difference in these AGA patients was 16.7 ± 1.2 torr, and the mean P_{CO_2} difference was −7.1 ± 0.4 torr. Cases with central placental location

were included in this analysis. P_{O_2} was always lower in the umbilical vein than in the mean uterine vein, and P_{CO_2} was always higher in umbilical venous than in uterine venous samples.

Uterine oxygen extraction and placental respiratory gas gradients in AGA and IUGR pregnancies. Table II compares values found in AGA and IUGR pregnancies for respiratory gases in the uterine venous drainage. For each patient the uterine venous values with the lowest oxygenation were compared as most representative of placental drainage, regardless of placental location. However, none of the differences between AGA and IUGR pregnancies are altered if mean uterine venous values are compared. As expected,

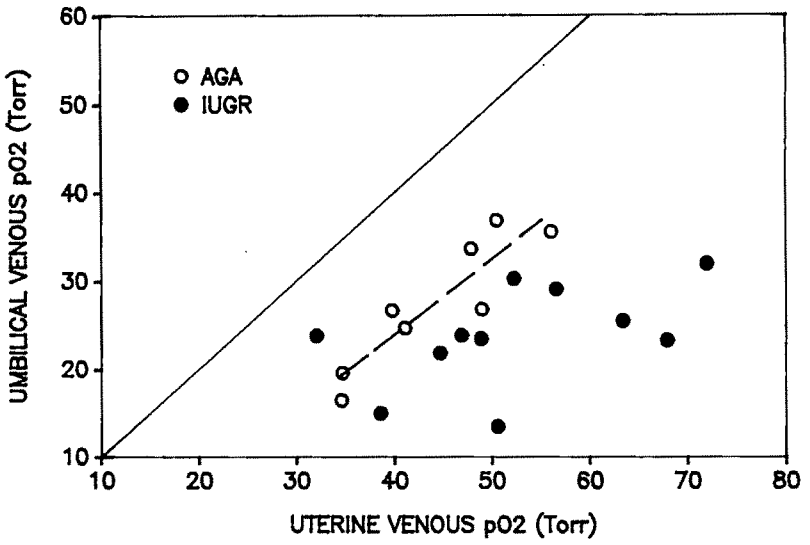

Fig. 2. Relationship between uterine venous and umbilical venous P_{O_2} in AGA (o) and IUGR (●) pregnancies. In this and subsequent figures, least oxygenated value for uterine vein was used. For AGA pregnancies regression line is presented ($y = -10.39 + 0.86x; r = 0.90, p = 0.002$). For IUGR pregnancies relationship is not significant. *Solid line* represents identity line.

IUGR fetuses had significantly higher hemoglobin concentrations. Oxygen content and saturation were significantly higher in the uterine vein of IUGR pregnancies ($p < 0.01$ and $p < 0.05$, respectively). The uterine arteriovenous difference for oxygen content was significantly greater in AGA pregnancies ($p < 0.05$), and the percent uterine oxygen extraction was significantly lower ($p < 0.05$) in IUGR pregnancies. The transplacental P_{O_2} and P_{CO_2} differences were calculated for the two groups of patients. Fig. 4 presents the mean transplacental difference between uterine vein and umbilical vein for P_{O_2} and P_{CO_2} in AGA and IUGR pregnancies. The gradient is significantly higher in IUGR pregnancies for both P_{O_2} ($p < 0.01$) and P_{CO_2} ($p < 0.001$).

Comment

The present study addresses the question of the pattern of respiratory gas exchange across the human placenta. Our data clearly demonstrate that in all cases the umbilical venous P_{O_2} is lower than the uterine venous P_{O_2} and, conversely, that umbilical venous P_{CO_2} is always higher than that in the uterine venous blood. Such a pattern of exchange is consistent with what has been termed a venous equilibrator. A variety of different perfusion patterns within the hemochorial placenta could lead to these results, including venous shunting (anatomic or diffusional) or uneven flow ratios. The current studies cannot discriminate between these possibilities. The hemochorial placenta of the human is different in this regard from the hemochorial placentas of guinea pigs and rabbits where the respiratory gas pattern is consistent with a countercurrent exchanger, i.e., umbilical venous P_{O_2} exceeds uterine venous P_{O_2}.[5, 6, 13] The present data for the human placenta are similar to data collected in the rhesus monkey. Two different in vivo studies have confirmed that the rhesus monkey placenta simulates a venous equilibrator.[2, 3] One hypothesis proposed by Bartels and Moll[14] is that the human placenta may function as a multivillous model. Such a model would be much more efficient than a venous exchanger, because umbilical venous P_{O_2} may be equal to or exceed maternal venous P_{O_2}.

By analyzing the uterine venous P_{O_2} that was lowest in each case, we sought to minimize our estimated uterine vein-umbilical vein P_{O_2} difference. In spite of this, the P_{O_2} difference was quite large (16.7 torr), comparable to that found in sheep (approximately 20 torr).

Another estimate of the minimal uterine venous-umbilical venous P_{O_2} can be obtained by using our data for uterine venous P_{O_2} in normal pregnancies (44.2 torr) compared with umbilical venous P_{O_2} measured at the same gestational ages from samples obtained at cordocentesis, without the stress of cesarean section (32.3 torr). Such analysis yields a P_{O_2} difference of 11.9 torr. Thus both attempts to minimize the P_{O_2} difference give estimates between 10 and 16 torr. Therefore, these data do not lend support to a multivillous model but rather favor a model of a venous equilibrator, similar to that found in the rhesus monkey and in the sheep.

A second point addressed by the present study concerns the interpretation of uterine venous metabolic data in pregnant women. One might have supposed that placental drainage would occur principally into the

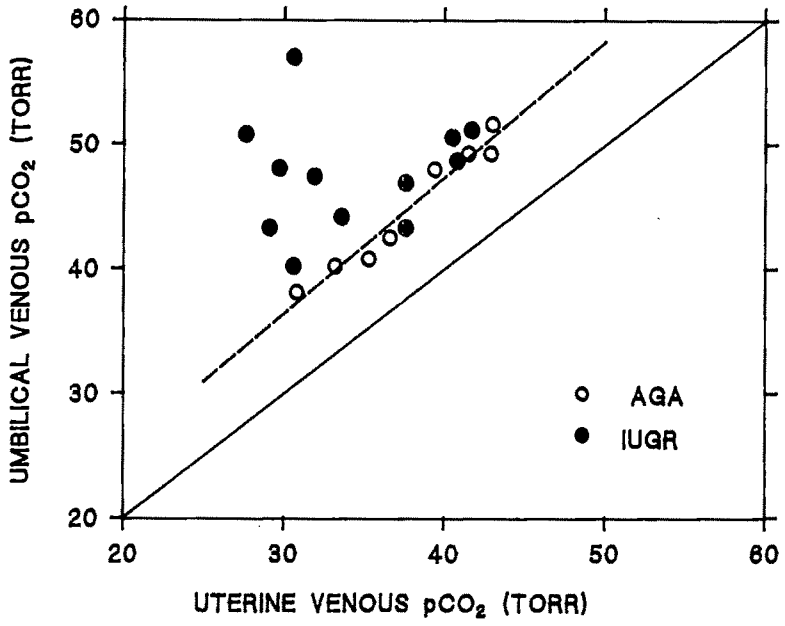

Fig. 3. Relationship between uterine venous and umbilical venous P_{CO_2} in AGA (○) and IUGR (●) pregnancies. For AGA pregnancies regression line is presented ($y = 3.61 + 1.09x$; $r = 0.98$; $p < 0.001$). For IUGR pregnancies relationship is not significant. *Solid line* represents identity line.

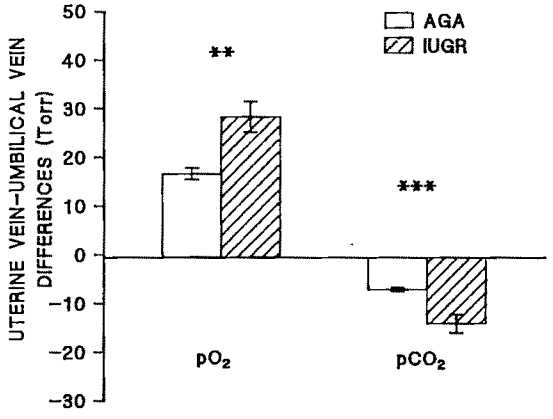

Fig. 4. Comparison of uterine venous-umbilical venous P_{O_2} and P_{CO_2} differences in AGA (□) and IUGR (▨) pregnancies. *Double asterisk*, $p < 0.01$; *Triple asterisk*, $p < 0.001$.

uterine vein on the same side of the uterus as the placenta. The present data clearly demonstrate that this is not a consistent relationship. There is a great deal of variability from one pregnancy to the next, a variability which was also found for the venous drainage of the rhesus monkey uterus.[2, 3]

The study focuses attention on a new question of considerable clinical relevance. The present data demonstrate that the placental venous drainage is not distributed evenly between the two uterine veins. It is possible that in some pregnancies the bulk of the venous drainage of the placenta occurs through the venous drainage on one side of the uterus. In these cases, occlusion of that uterine vein, which could occur from positional changes in the mother, would markedly affect placental transport. This has been demonstrated in the two studies in rhesus monkeys and is a question which may now be open to investigation in pregnant women, using improving techniques for ultrasonographic visualization of vessels and Doppler velocimetry.

The data in the present study were collected at the time of elective cesarean section. Inevitably, there are changes in uterine tone and in placental perfusion induced by manipulation of the uterus or by the uterine incision. Such changes would tend to increase the P_{O_2} difference between the two venous circulations, particularly at high P_{O_2}, reducing the slope of the relationship between umbilical venous and uterine venous P_{O_2} (Fig. 2). The major point demonstrated in Fig. 2 is that umbilical venous P_{O_2} is always lower than uterine venous P_{O_2} at all levels studied.

It is useful to compare these data with other species. In the present study the coefficient of oxygen extraction for normal pregnancies is 32.1% ± 3.8%, similar to the value of 24.2% ± 1.1% obtained in pregnant sheep[15] and much lower than the value of 60.6% ± 0.3% found for pregnant rabbits[16] and 71.7% ± 0.5% for guinea pigs.[17] These differences are reflected in much lower uterine venous P_{O_2} values in rabbits, 29.3 ± 0.1 torr than in sheep, 50 ± 1 torr[16] and also lower than our results for human pregnancies, 44.2 ± 3 torr. These data suggest that the rate of perfusion of the human uterus per millimole per liter of

oxygen used is quite large compared to small mammals such as the guinea pig and rabbit. If one accepts the estimates of uterine blood flow in man of approximately 600 ml/min[18] and the average value for the lowest uterine oxygen saturation measured in the present study (66.8%), the uterine oxygen consumption is in the order of 1.5 mmol/L/min. This is not dissimilar from the measured oxygen consumption in pregnant sheep in late gestation (1.65 mmol/L/min).[8]

Comparison of IUGR and normal pregnancies. In the present study there are two striking observations that come out of a comparison of the data for IUGR and normal pregnancies. The first is that uterine venous oxygen content is higher and the coefficient of oxygen extraction is less in IUGR pregnancies than in normal pregnancies (Table II). There is no evidence from these data that the uterus is underperfused relative to oxygen demands in IUGR pregnancies. However, this does not exclude the possibility that a reduction in uterine blood flow earlier in pregnancies may alter the growth and maturation of the placenta and fetus. Doppler velocimetry studies have provided evidence for increased resistance in uterine vessels of IUGR pregnancies associated with maternal hypertension.[19] But the present data make clear that any reductions in uterine flow in IUGR pregnancies are at least proportional to the decreased oxygen requirements of the IUGR uterus.

The second finding of note in the present study is that of an increased transplacental P_{O_2} and P_{CO_2} difference in IUGR patients. This finding of itself has two important physiologic implications. The first is that given the higher oxygen concentration in uterine venous blood of IUGR patients, the increased transplacental respiratory gas gradients demonstrate a decreased placental permeability for IUGR placentas. Presumably this is a reflection of a markedly decreased surface area in these small placentas. A number of histologic changes have been described in IUGR placentas, which would effectively decrease the diffusing capacity or increase shunting of uneven perfusion.[20, 21] More recently, such histopathologic changes in the villi of IUGR placentas have been correlated with abnormal Doppler velocimetry findings.[22-24]

Another potential consequence of an increased transplacental respiratory gas gradient is that umbilical venous P_{O_2} may be decreased in these pregnancies. Data collected by our group[25] and by Nicolaides et al.[26] at cordocentesis have shown that the majority of IUGR fetuses have normal umbilical venous P_{O_2}. For those IUGR fetuses who develop hypoxia, our data help clarify the reasons for such findings, namely the reasons reside within the placenta and its fetal perfusion and are not a function of decreased uterine blood flow since any reduction in uterine flow does not exceed a proportional reduction in oxygen requirements by the smaller uterine contents of IUGR pregnancies. Doppler velocimetry studies of the umbilical circulation have supported the interpretation of an increased resistance to flow within the umbilical vascular bed.[27, 28]

There is a striking similarity between these clinical data and those recently reported by Bell et al.[29] in heat-stressed ewes with IUGR fetuses. They found that uterine venous oxygenation decreased, with an increased venous P_{O_2} difference across the placenta. The increased venous P_{O_2} difference was a function of placental size with the smallest placentas showing the largest increase. Thus the reasons for fetal hypoxia in IUGR pregnancies are beginning to be clarified in both clincial and animal studies with a remarkable concordance in the findings.

Long-term acid-base measurements in the fetal and maternal baboon

Salha S. Daniel, PhD, L. Stanley James, MD, Gregory MacCarter, MA, Hisayo O. Morishima, MD, PhD, and Raymond I. Stark, MD

New York, New York

OBJECTIVE: The purpose of the study was to examine the relationship between maternal and fetal acid-base indexes in the baboon.

STUDY DESIGN: Eight animals maintained in a tether system were studied during the third trimester. Results were analyzed using analysis of variance.

RESULTS: After recovery from surgery, pH in carotid artery blood of the fetus was 7.40 ± 0.027 (mean ± SD), Po_2, 27.5 ± 3.45 mm Hg; Pco_2, 34.0 ± 2.37 mm Hg; base deficit, 3.0 ± 2.15 mEq/L; Hot, 33.4% ± 2.69% and HbO_2, 61.3% ± 8.65%. The corresponding values in the mother were 7.48 ± 0.035, 100.7 ± 9.44 mm Hg, 26.4 ± 2.95 mm Hg, 3.6 ± 1.71 mEq/L, 32.6% ± 4.0% and 97.9% ± 1.28%, respectively. All indexes remained essentially the same until the onset of active labor, at which time the fetus became slightly acidotic and hypoxemic (pH < 7.35, HbO_2 < 50%).

CONCLUSION: The baboon fetus has slightly higher pH_2 and lower $Paco_2$ than the human fetus and Pao_2, base deficit, and maternal-fetal gradients across the placenta in these two primate species are comparable. (Am J Obstet Gynecol 1992;166:707-12.)

Key words: Acid-base, fetus, baboon, third trimester

Ethical considerations in humans and technical difficulties in nonhuman primates have limited the acquisition of data on fetuses in these species. Observations on the normal intrauterine environment, interrelations between mother and fetus, and responses to changes in this environment have been made most extensively in the chronically instrumented pregnant sheep. Significant progress has been made in the last decade in establishing similar methods for studies of nonhuman primates. Nonetheless, long-term data on chronically instrumented unanesthetized fetuses in primate species are still scanty.[1-3] In recent years, there have been several reports of blood sampling from the human fetus during the second and third trimesters of pregnancy.[4-6]

We now report the results of serial long-term measurements of acid-base indices in the chronically catheterized baboon fetus and its mother maintained in a tether system. The purpose of the current research is to examine the relationship between maternal and fetal arterial pH, Pco_2, Po_2, and base deficit in this species and to compare these values with those reported for the human and sheep during the third trimester of pregnancy.

Material and methods

Data were obtained on eight pregnant baboons (*Papio papio* and *Papio anubis*) and their fetuses starting on the day of surgery and continuing until delivery. A detailed description of the maintenance of the colony, breeding, preconditioning to the tether and backpack system, anesthesia, surgery, and postoperative care were reported previously.[3]

Surgery and care. All animals were maintained in an American Association for Accreditation of Laboratory Animal Care approved facility in accordance with published guidelines[7] and met the standards of care of the Department of Agriculture. Before implementation, research protocols were approved by the Committee on Animal Care and Use at the Columbia College of Physicians and Surgeons.

The animal was first tranquilized with an intramuscular injection of ketamine (5 to 10 mg/kg) and atropine sulfate (0.2 mg). Surgery was performed under anesthesia achieved with halothane (0.025% to 2.0% as required) with a mixture of oxygen and nitrous oxide (4:6) at 132 ± 2.7 days' gestation (range 130 to 136 days, term approximately 175 days). Maternal femoral artery and vein were cannulated with Tygon microtubing (inner diameter 1.3 mm, outer diameter 2.3 mm), and the tips of the catheters were placed at the level of the aortic bifurcation and inferior vena cava, respectively. Fetal carotid artery and internal jugular

*$p > 0.05$ Compared with day 3.

vein were cannulated with Tygon tubing (inner diameter 1.0 mm, outer diameter 1.8 mm), advanced to the level of the aortic arch and superior vena cava, respectively (4 to 6 cm). A similar catheter, but with multiple holes at the end, was attached to the fetal neck resting in the amniotic cavity to record intraamniotic pressure and replenish amniotic fluid if necessary.

All fetal catheters were brought out through the maternal peritoneum and fascia; both maternal and fetal catheters were then tunneled first to the flank of the mother and then to an infrascapular site over which the back pack was later attached.

On return of the baboon to the colony, the color-coded catheters were attached to appropriate transducers and extension tubing. This tubing was protected inside a flexible stainless steel cable that connected the backpack to a swivel device at the top of the cage. Thus continuous monitoring of pressure and sampling of blood was allowed with minimal restraint of the mother. With prior conditioning, the behavior patterns of mothers in the tether were virtually identical to those seen normally in individually caged animals.

All vascular catheters were infused continuously with normal saline solution containing 1.5 U/ml heparin and 500 U/ml aqueous penicillin at rates of 0.2 to 0.5 ml/hr to the fetus and 1 to 4.0 ml/hr to the mother, with flow pumps attached to the swivel (Holter #904 & 907, respectively). The mother was maintained on intravenous hydration through the first 24 to 72 hours, until she resumed her normal activities. Analgesia was provided with intravenous infusion of morphine sulfate at 0.1 to 1 mg/hr for at least the first three nights after surgery.

Recording and sampling. Continuous recordings were begun immediately after the animal returned from surgery. All biophysical recordings were made with appropriate preprocessors on an eight-channel strip chart recorder for on-line management and eight-channel analog tape recorder. All recording equipment was located in a room adjacent to the study cage facility.

Simultaneous maternal and fetal arterial samples of approximately 0.7 ml volume were obtained anaerobically three to five times a week at about 3:00 PM to control for the effects of any prior nocturnal uterine contractions or diurnal variation. Each sample was collected after withdrawing a volume equal to 2 to 2.5 times the volume of dead space of the catheters (1.1 ml for fetal and 1.5 for maternal) to avoid dilution or introduction of air into the samples. Samples were analyzed for hematocrit, acid-base, and blood gases (Radiometer pH Gas Monitor #ABL3C) and oxygen saturation (IL Co-oximeter #282). Coefficient of variations for repeated measures on the individual samples are 0.006 for pH, 1% for P_{CO_2}, 2% for P_{O_2}, and 3% for hemoglobin oxygen saturation.

Results are presented as mean ± SD; differences in mean values are considered significant when $p < 0.05$. Values in the mother and fetus over the third trimester were analyzed with one-way analysis of variance for repeated measures. Comparison between maternal and fetal values were made with the Student *t* test for paired samples. Correlation analyses between maternal and fetal values were peformed with the Systat computer program to determine a best fit linear regression.

Results

Maternal and fetal outcome. Postoperative uterine contractions were present in the evening hours in six of the eight animals. These usually continued for 3 to 5 days after surgery and completely disappeared thereafter in four of the above animals. In one animal, mild to moderate uterine contractions continued to appear each night until delivery at 171 days' gestation. In another animal some contractions were also present dur-

†$p < 0.01$ compared with day 3.

ing the daytime for the first week after surgery. Morphine was given to all animals during the first three postoperative nights; morphine was continued for four or five nights in two animals and during the daytime also in one other because of persistent uterine contractions. All fetuses were alive until time of delivery, which occurred at 160 ± 3.1 days' gestation (range 151 to 171 days); one animal was delivered by cesarean section at 169 days and the remaining seven delivered vaginally. The mean duration of these studies was 28 ± 6.9 (range 21-39 days).

Maternal acid-base status. Mean acid-base indices in arterial blood of the eight pregnant baboons from the day of surgery to the day preceding delivery are given in Table I. Immediately after surgery the pregnant baboon showed evidence of mild metabolic acidosis, which in most cases was absent by the fourth or fifth postoperative day when the animal had resumed a normal diet and overnight uterine contractions had subsided. Values during the subsequent days reflected a state of slight respiratory alkalosis. Apart from a tendency for hematocrit to decrease with gestation, all values remained essentially unchanged throughout the period of study (r values ranging from 0.13 to 0.41 and p values >0.1).

Fetal acid-base status. Fetal arterial pH, blood gas, and hematocrit values are summarized in Table II. On the day of surgery fetal pH was significantly lower than subsequent values while Pa_{CO_2} and hematocrit were higher. Base deficit remained high for the first 2 to 3 days. Subsequent fetal arterial pH, Pc_{O_2}, base deficit, and hematocrit values did not change significantly during the third trimester (r values for correlation with gestation ranged from 0.07 for Pc_{O_2} to 0.41 for Po_2 and p values >0.1); the ranges were as follows: pH 7.33 to 7.43, Pa_{CO_2} 29 to 39 mm Hg, base deficit 7 to −0.6 mEq/L, and hematocrit 31% to 39%. Fetal Pa_{O_2} was higher on the day of surgery than during the following days, when it stabilized; however, fetal oxygenation was essentially unchanged throughout the period studied.

Fetal-maternal gradient for pH remained remarkably stable, being −0.095 ± 0.037 on the first postoperative day and −0.096 ± 0.015 on the day before delivery. Gradients for Pa_{CO_2} were 6.9 ± 4.29 on day 1 and 7.0 ± 3.19 mm Hg the day before delivery; the corresponding gradients for base deficit were 1.5 ± 2.08 and 1.4 ± 1.70 mEq/L, respectively. When values obtained on the day of surgery and during active labor were excluded, there was a strong, positive correlation between maternal and fetal pH ($r = 0.693$, $p = 0.001$), Pc_{O_2} ($r = 0.757$, $p < 0.001$), base deficit ($r = 0.680$, $p = 0.008$), and Po_2 ($r = 0.635$, $p = 0.021$ but only when animal #433 depicted in Fig. 2 was excluded; see below).

Serial acid-base values in arterial blood of baboon #406 and her fetus are shown in Fig. 1. This animal had little or no uterine activity after surgery (at 131 days) until two nights before delivery (at 152 days). Immediately after surgery the mother had a relative respiratory acidosis compared with the normal value during pregnancy (pH = 7.406, Pa_{CO_2} 40.7); however, the values returned to normal by the first postoperative day and remained unchanged until the onset of active labor. The range of pH was 7.47 to 7.51, Pa_{O_2} 90-110 mm Hg, Pa_{CO_2} 26 to 34 mm Hg, and base deficit 0.5 to 4 mEq/L. During active labor and delivery the animal developed a moderate metabolic acidosis (base deficit 6.2 mEq/L). The fetus had both respiratory and metabolic acidosis immediately after surgery: pH 7.25, Pa_{CO_2} 47 mm Hg and base deficit 7 mEq/L. Values returned to normal within 2 days and remained stable until labor was established. The average normal values

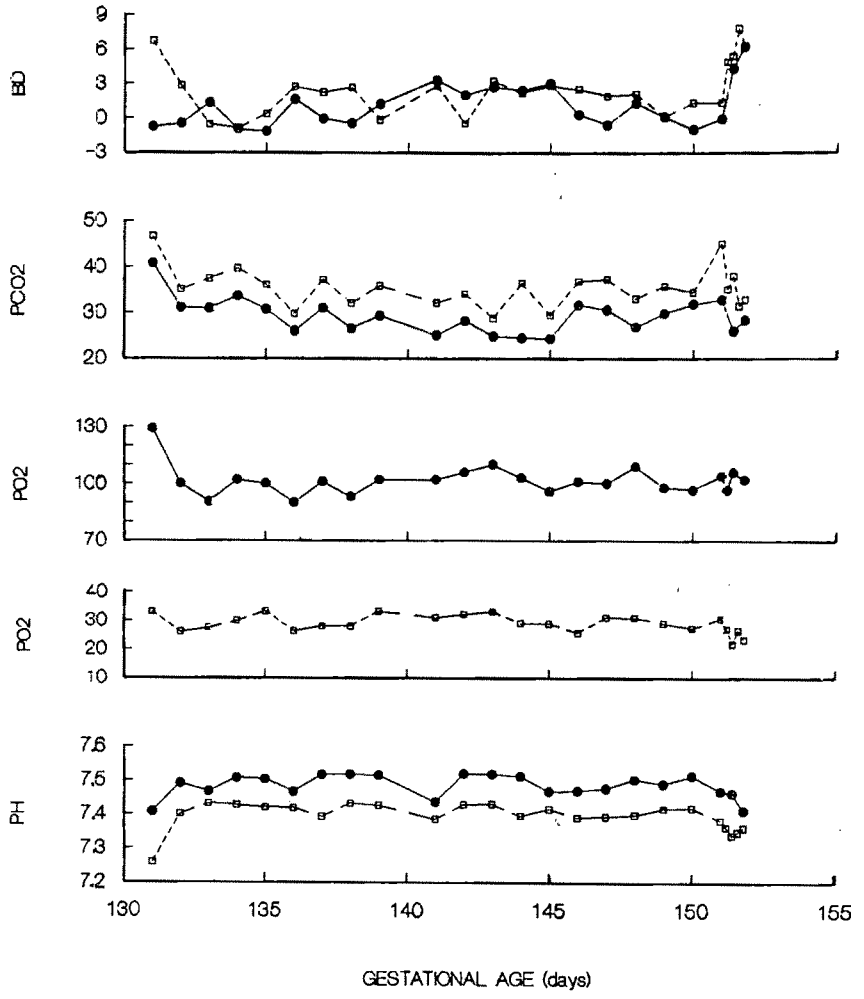

Fig. 1. pH, Pa_{O_2}, and base deficit in baboon #406 and her fetus from day of surgery at 131 days until delivery on day 152. This animal exhibited very mild or no uterine contractions until day 150. □--□, Fetus; ●——●, mother.

were pH 7.42 ± 0.022, Pa_{O_2} 30 ± 2.5 mm Hg, Pa_{CO_2} 34 ± 3.2 mm Hg, and base deficit 1.5 ± 1.52 mEq/L. Fetal acidosis and hypoxemia developed with the establishment of labor. The lowest values for pH (7.34) and Pa_{O_2} (22 mm Hg) and highest values for Pa_{CO_2} (45 mm Hg) and base deficit (8 mEq/L) occurred about 1 hour before delivery. Maternal-fetal gradients in acid-base indices were greatest on day of surgery and at delivery, whereas during the remainder of the study period most of the daily variations in fetal acid-base could be accounted for by those of the mother.

Fig. 2 shows daily acid-base values in baboon 433. This animal had mild to moderate uterine contractions (pressures of 25 to 40 mm Hg at a rate of 3 to 4/10 minutes) every night (for 3 to 5 hours) until delivery at day 171. Maternal Pa_{O_2} values in this animal were in the same range as in animal 406; however, pH and Pa_{CO_2} were slightly lower (range 7.44 to 7.49 for pH and 24 to 31 mm Hg for Pa_{CO_2}), whereas base deficit was slightly higher (2 to 6 mEq/L). Fetal pH, Pa_{CO_2}, and base deficit stabilized by postoperative day 2; however, as in the mother, pH and Pa_{CO_2} were slightly lower (7.38 ± 0.020 and 31 ± 2.3), whereas base deficit was higher (6 ± 1.4 mEq/L). On the other hand, Pa_{O_2} showed a gradual decline from 27 to 29 mm Hg a few days after surgery to values as low as 18 to 21 mm Hg in the days before delivery. In general, maternal-fetal gradients of the various indices for this animal were greater than those in other animals who had minimal uterine contractions during the period of the observations.

Comment

The present long-term observations were obtained from chronically catheterized fetal baboons and their mothers maintained under stable conditions with a tethering and backpack system described previously.[5] During the third trimester, acid-base indices in fetal

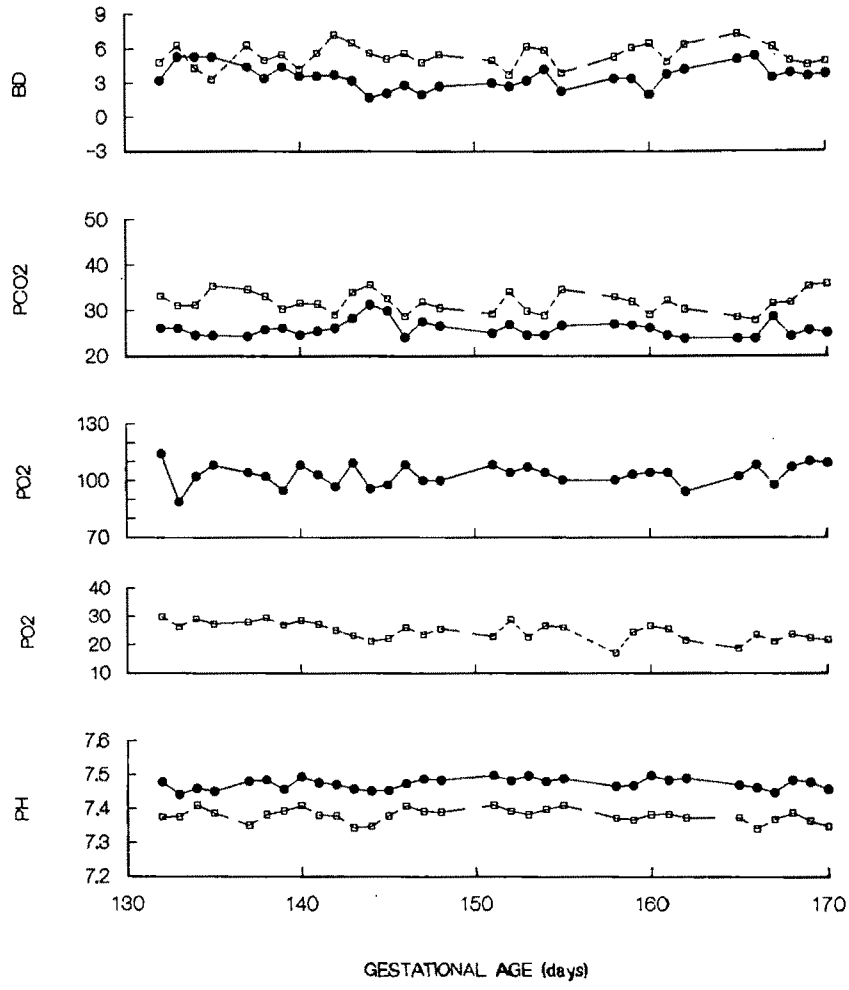

Fig. 2. pH, Pa_{O_2}, Pa_{CO_2}, and base deficit in baboon 433 and her fetus from day of surgery at 132 days until day before delivery at 171 days. This animal had uterine contractions (30-40 mm Hg height and 3 to 4/10 mins) for ≥4 hours every evening. □--□, Fetus; ●——●, mother.

carotid artery, with the exception of P_{O_2}, were within the normal range for adult animals. These indices, including P_{O_2}, stabilized within 1 to 2 days after surgery and remained essentially unchanged until the onset of active labor. As expected, data demonstrate a consistently lower arterial pH in the fetus (average −0.095), a higher P_{CO_2} (average 7 mm Hg), and a higher base deficit (average 1.5 mEq/L) than the corresponding values in the mother.

When compared with values reported in pregnant sheep, our results are similar with regard to pH; however, P_{CO_2} values are slightly lower and base deficit and P_{O_2} higher in the pregnant baboon.[8-12] It is possible that these differences are related to the overnight uterine contractions that occurred in some animals. In addition, although the baboons were extensively preconditioned to the tethering system and appeared undisturbed during the sampling of blood, the presence of a small, combined respiratory alkalosis and metabolic acidosis could be due to some degree of agitation. However, levels of catecholamines, vasopressin and β-endorphin in maternal plasma were within the range of unstressed, pregnant animals.[3, 12] Fetal P_{O_2} values in the carotid artery were 8 to 10 mm Hg higher in the baboon than the corresponding values in the sheep fetus; however, because of the differences in dissociation curves, this was not reflected in hemoglobin oxygen saturation. The baboon fetus also had higher pH and base deficit and lower Pa_{CO_2} values when compared with those found in the fetal sheep. Maternal-fetal gradients of pH, Pa_{CO_2}, and P_{O_2} but not base deficit were generally smaller in the baboon than those reported for the sheep. This may reflect a higher diffusion rate for carbon dioxide and oxygen across the placenta in the baboon.

The range of pH values in humans taken from the umbilical artery of the fetus at the time of cordocentesis during the second and third trimesters is reported to

be 7.32 to 7.37, whereas the range in maternal arterial or free flowing venous blood taken at the same time is 7.36 to 7.45.[4-6] These values are lower than those we obtained in the baboon. The ranges for P_{CO_2} reported in humans are generally higher than the present results on the baboon, whereas values for P_{C_2} and base deficit in the two primate species appear to be in the same range for both the mother and the fetus. Whether these differences are because sampling in the human necessitates some degree of manipulation or because the baboons may be slightly agitated cannot be determined at the present time. It should also be pointed out that fetal samples in the present study were taken from the carotid artery during the third trimester; the results reported on human fetuses were taken from the umbilical artery during midgestation. P_{O_2} values in the umbilical artery are expected to be 2 to 4 mm Hg lower than those in the carotid artery, and there is a tendency for fetal P_{O_2} values to fall with gestational age.[5, 6, 13] In spite of these differences, maternal-fetal gradients for all indices are essentially the same in both species, reflecting the similarities in placental transport of components of acid-base.

Apart from preliminary results we published earlier, there are no reported data on acid-base value in the chronically instrumented, unanesthetized pregnant baboon and its fetus.[3] The only values in the chronically instrumented nonhuman primate fetus were reported by Jackson et al.[2] in the rhesus monkey. These are very similar to human data; however, the animals were sedated with ketamine or sernylan for the purpose of the study.

Reports in humans and more recently in sheep have shown that there is usually a decrease in fetal P_{O_2} and an increase in hemoglobin from the second to the third trimester without a change in oxygen content.[5, 6, 13] We found no such trend in our animals. However, our observations were all obtained during the third trimester (average duration 21 to 39 days). There was a tendency for Pa_{O_2} to fall in the one animal (Fig. 2) observed for the longest period of time; this animal had mild uterine contractions during the evening throughout the study. It is therefore not possible to determine whether this decrease in Pa_{O_2} and lack of correlation with maternal Pa_{O_2} were due to the periodic reduction in uterine blood flow or represented a true tendency for diminished arterial oxygen tension during the third trimester in the baboon fetus.

In conclusion, our results demonstrate that acid-base indices of the unanesthetized fetal and maternal baboon maintained in a tether system stabilize by the third postoperative day and remain unchanged throughout the third trimester until the onset of active labor. Although Pa_{O_2} and base deficit in both mother and fetus are comparable with those in humans, fetal pH is higher and Pa_{CO_2} is lower. Maternal-fetal gradients of these values, however, are the same in the two species. It is speculated that these differences are due to the conditions under which samples were obtained rather than true species differences.

We thank Dr. W. H. Niemann for his valuable advice in conditioning and maintaining the animals and Mrs. Alice White for her help in organizing the data.

The effects of glycemia on breathing movements and plasma prostaglandin E concentrations in the sheep fetus

A.L. Fowden, PhD,[a] S. Thian, BA,[a] M. Silver, PhD,[a] M.M. Ralph, PhD,[b] and R. Harding, PhD[b]

Cambridge, England, and Clayton, Victoria, Australia

OBJECTIVE: The purpose of this study was to determine the roles of fetal plasma glucose and prostaglandin E in controlling fetal breathing movements.

STUDY DESIGN: Five late pregnant ewes with catheterized twin fetuses were fasted for 48 hours; one fetus was kept normoglycemic (by glucose infusion) and the other allowed to become hypoglycemic during this period. Fetal breathing movement and fetal and maternal plasma prostaglancin E and glucose concentrations were measured throughout. Data were analyzed by paired and unpaired *t* tests.

RESULTS: The mean incidence of fetal breathing movement was significantly greater in the normoglycemic fetuses that in the hypoglycemic twins at the end of the fast ($p < 0.05$), whereas plasma prostaglandin E levels increased significantly ($p < 0.05$) and to the same extent in both groups of fetuses.

CONCLUSION: The reduced incidence of ovine fetal breathing movement that occurs during maternal fasting appears to be primarily caused by fetal hypoglycemia and does not directly involve changes in fetal plasma prostaglandin E. (AM J OBSTET GYNECOL 1992;166:713-9.)

Key words: Fetal breathing, hypoglycemia, prostaglandin E

Breathing movements are a normal feature of fetal life. They occur episodically throughout the latter half of gestation and are related to the metabolic and endocrine status of the fetus.[1] In particular, the circulating glucose concentration appears to be an important influence on fetal breathing activity in late gestation.[1, 2] In the fetus sheep near term, hyperglycemia increases the incidence of fetal breathing movements, whereas hypoglycemia, induced by fasting or insulin infusion, decreases fetal respiratory activity.[3-6] Similar observations have been made in the human infant during late gestation.[2]

Although fetal breathing activity appears to be closely related to glucose availability in utero, it is still not clear whether these changes in fetal breathing movements are due to variations in the fetal glucose concentration per se or whether other nutritional or hormonal changes are involved. Certainly, infusions of glucose into hypoglycemic fetuses of fasted ewes restores the normal incidence of fetal breathing movements, but the glucose levels achieved in these experiments were twice the normal fetal concentrations.[5] More recent studies have suggested that the low incidence of fetal breathing movements seen during fetal hypoglycemia may be due, in part to a concomitant increase in the prostaglandin E_2 (PGE_2) concentration in fetal plasma.[6]

Prostaglandins have major effects on fetal breathing activity in the sheep.[7] Infusion of prostaglandins, particularly PGE_2, reduces the incidence of fetal breathing movements in sheep, whereas conversely, inhibition of prostaglandin synthesis stimulates fetal breathing activity.[8-10] Prostaglandin production in utero is also known to be related to maternal nutritional state.[11, 12] Increases in uterine prostaglandin synthesis occur during dietary restriction, and an inverse relationship between the plasma prostaglandin and glucose concentrations is observed in the fetus and pregnant ewe when nutrient availability is manipulated during late gestation.[12, 13] Hence in this study the roles of plasma prostaglandin E (PGE) and glucose in controlling fetal breathing movements have been examined more closely by comparing fetal breathing movements and plasma PGE concentrations during maternal fasting in twin sheep fetuses in which one fetus was allowed to become hypoglycemic while the other was maintained in a normoglycemic state by fetal glucose infusion.

Material and methods

Animals. Five Welsh Mountain ewes carrying twin fetuses of known gestational age were used. All 10 lambs were alive at delivery, which occurred at a mean gestational age of 143.2 ± 1.2 days ($n = 5$). Mean birth weight was 2.135 ± 0.063 kg ($n = 10$).

Operative procedures. Between 112 and 117 days of gestation, anesthesia was induced with thiopental and maintained with halothane (1.5% in nitrous oxide and oxygen) after intubation. With established procedures,[12, 14] catheters were inserted into the carotid artery, jugular vein, trachea, and amniotic sac of each

twin fetus and into a uterine vein and dorsal aorta of the ewe. Antibiotics were given intravenously to the fetus (100 mg ampicillin [Penbritin]) and intramuscularly to the mother (10 ml Streptopen) at the end of surgery. Normal feeding patterns were generally restored within 24 to 48 hours of operation, but no experiments were carried until 12 to 21 days after surgery.

Experimental procedures. Food but not water was withdrawn from the ewes for 48 hours beginning at 131 to 136 days of gestation at either 9 AM ($n = 2$) or 5 PM ($n = 3$). Glucose was infused intravenously into one twin of each pair at 300 mg/hr for the first 24 hours, 600 mg/hr for the next 12 hours, and then at 900 mg/hr for the last 12 hours of the 48-hour fast. The twin to be infused was chosen randomly.

During the experimental period, 8 ml blood samples were taken from the uterine vein and fetal and maternal arteries either between 9 and 10 AM ($n = 2$) or 4 and 5 PM ($n = 3$) starting 24 hours before the fast was begun and continuing until 24 hours after the animals were refed. A small aliquot of blood (0.5 ml) was used for analyses of pH, P_{O_2}, P_{CO_2}, hemoglobin concentration, and oxygen saturation with Radiometer equipment (ABL 330 and OSM2, Radiometer American, Inc., Westlake, Ohio). Blood oxygen content was calculated from the hemoglobin and oxygen saturation values. Two milliliters of blood was added to chilled tubes containing aspirin (1.4 mg) and ethylenediamine tetraacetic acid (0.10 mg) for analysis of PGE. These samples were centrifuged at 4° C, and an equal volume of 0.12 mmol/L methoxyamine hydrochloride in sodium acetate buffer (1 mol/L, pH 5.6) was added to the plasma. Plasma samples with added methoxyamine hydrochloride were left at room temperature for 24 hours then frozen at −20° C until analysis. The remainder of the blood samples (≈5 ml) were added to tubes containing ethylenediamine tetraacetic acid and centrifuged at 4° C. The plasma from these samples was stored at −20° C until required for metabolite and other hormonal analyses.

Recordings of fetal breathing movements were made for 4 to 6.5 hours between 10 AM and 4:30 PM on the day before, the day after, and the 2 days of the 48-hour fast. Tracheal and amniotic fluid pressures were measured in each fetus with standard pressure manometers and displayed on an eight-channel Lectromed recorder together with the electronically derived difference between the tracheal and amniotic pressures. All operative and experimental procedures were approved and licensed by the appropriate authorities.

Biochemical analyses. Glucose concentrations were measured in plasma that was deproteinized with zinc sulfate (0.3 mol/L) and barium hydroxide (0.3 mol/L) with glucose oxidase.[12] Plasma PGE was assayed by radioimmunoassay against PGE_2 methyloxime standards with use of an antiserum raised in goats against the methyloxime of PGE_2.[15] Detailed procedures and specificity of the PGE assay for ovine plasma have already been published.[12] The limit of sensitivity of the assay was 0.5 nmol/L, and intraassay and interassay coefficients of variation were ≤10% and 21.4%, respectively, for the assays required for this study. Because the antiserum did not distinguish between PGE_1 and PGE_2,[12] plasma PGE concentrations have been expressed as PGE_2 equivalents.

Data analyses. An episode of fetal breathing movements was defined as a series of negative deflections in tracheal pressure, from which amniotic pressure had been subtracted, that were >0.8 mm Hg and lasted longer than 0.5 minute. The incidence of fetal breathing movements was calculated as the total amount of time within a recording period (4 to 6.5 hours) occupied by fetal breathing movements and expressed as a percentage. The amplitude of the negative pressure deflections (tracheal pressure − amniotic pressure) was measured every 20 or 30 seconds during each episode of fetal breathing movements with a Cal Comp digitizing tablet with the Sigma scan program (Jandel Scientific, Corte Madera, Calif.), and the mean value was calculated for all episodes of fetal breathing movements during a recording period in each fetus.

Mean ± SEM are used throughout and statistical analyses were made according to the methods of Armitage.[16] Statistical significance was assessed by paired and unpaired t tests. Linear regression was also used to assess the relationship between fetal breathing movements and the plasma concentrations of glucose and PGE. In one glucose-infused fetus the infusion pump became detached for 8 hours during the last 12 hours of the 48-hour period of food withdrawal. Consequently, data obtained from this fetus at 48 hours of fasting have not been included in the mean values for the glucose-infused fetuses at the end of the fast.

Results

Basal values. Before the fast, fetal blood gas tensions, pH, and oxygen content were within the normal range of values,[14] as were the plasma concentrations of glucose and PGE in the fetus (Table I) and ewes (2.98 ± 0.26 mmol/L and 11.60 ± 1.11 nmol/L, respectively, $n = 5$). The incidence and amplitude of fetal breathing movements before the fast were also similar to values reported previously for fetal sheep in late gestation (Table I).[1] Before the fast began, there were no significant differences in plasma glucose, PGE, blood gas status, or incidence or amplitude of fetal breathing movements between the pairs of fetuses that were subsequently glucose infused or uninfused during the fast (Table I).

Effects of nutritional manipulation

Metabolite and hormone concentrations. Fasting significantly reduced plasma glucose levels in the mother and

Table I. Values (mean ± SE) for arterial blood gas tensions, pH, oxygen content, plasma concentrations of glucose and PGE, and mean incidence and amplitude of fetal breathing movements before fasting in twin sheep fetuses that were subsequently uninfused ($n = 5$) or infused with glucose ($n = 5$) during a 48-hour period of maternal fasting

†Significantly less than value in infused fetuses, $p < 0.01$ (paired and unpaired t test).

uninfused fetus at 24 and 48 hours (Table II). Infusion of glucose into the other fetus of the pair maintained normoglycemia; plasma glucose levels were not significantly different from prefasting values at 24 and 48 hours and were significantly greater than those in the uninfused fetuses after 48 hours of fasting (Table II). In the fetus in which glucose infusion failed, the plasma glucose level was maintained for the first 24 hours of maternal fasting but had fallen to a value similar to that in the uninfused fetuses by the end of the 48-hour fast. After refeeding was carried out for 24 hours, plasma glucose levels in the mothers and uninfused fetuses were not significantly different from prefasting values (Table II).

Maternal fasting led to increases in plasma PGE concentrations in the ewes and uninfused, hypoglycemic fetuses, as reported previously.[12] The increment in maternal arterial plasma PGE during fasting varied widely between individuals (range 2.90 to 15.16 nmol/L), and hence the mean change in plasma PGE was not significant, even at the end of the 48-hour period of fasting ($p > 0.05$, Table II). Significant increases in fetal plasma PGE levels were observed at the end of the fast in both the uninfused and glucose-infused fetuses (Table II). The increment in fetal plasma PGE from the mean prefasting value was similar in the uninfused (+2.52 ± 0.53 nmol/L, $n = 4$) and glucose-infused (+2.80 ± 0.74 nmol/L, $n = 4$) fetuses. There were also no significant differences in the absolute PGE concentrations between the two groups of fetuses at any time during the experimental period (Table II). Refeeding the ewes lowered plasma PGE concentrations in the mother and both groups of fetuses; the values observed 24 hours after refeeding were not significantly different from those measured before fasting began (Table II).

No significant changes in fetal blood gas tensions, pH, or oxygen content occurred during maternal fasting in either the glucose-infused or uninfused groups of fetuses ($p > 0.05$ all cases).

Fetal breathing movements. In common with previous studies[3, 12] the incidence of fetal breathing movements decreased significantly during maternal fasting in the fetuses that became hypoglycemic (Fig. 1). The mean reduction in the incidence of fetal breathing movements during the 48-hour period of fasting was 58% ± 11.0% ($p < 0.01$) in these five fetuses. By contrast, there was no significant change in the incidence of fetal breathing movements during maternal fasting in the glucose infused fetuses (Fig. 1); the mean inci-

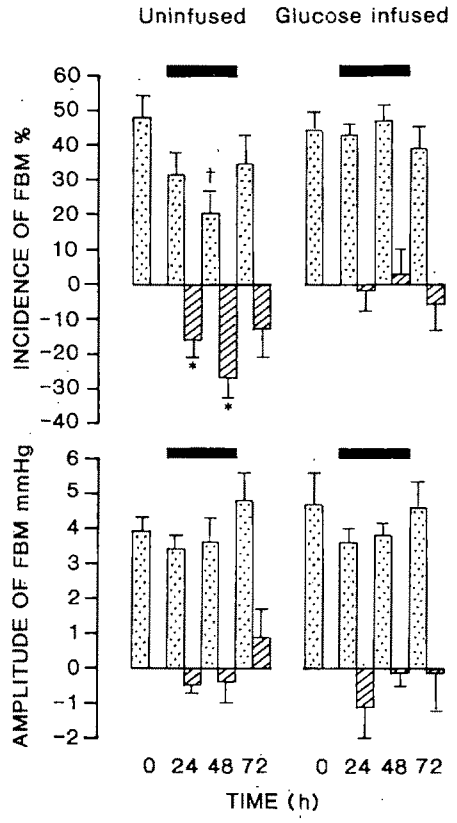

Fig. 1. Incidence and amplitude (mean ± SE) of fetal breathing movements (FBM) *(dotted bars)* before, during, and after 48-hour period of maternal food withdrawal *(solid horizontal bars)* and mean changes in value *(hatched bars)* from time 0 in fetuses uninfused ($n = 5$) or infused with glucose during fast ($n = 5$, except at 48 hours when $n = 4$). *Asterisk*, Significant change from time 0 value, $p < 0.05$; *Dagger*, Significantly different from infused fetuses, $p < 0.05$.

dence of fetal breathing movements in these fetuses was therefore significantly greater than that in the uninfused fetuses at the end of the fast (Fig. 1). After refeeding for 24 hours, the incidence of fetal breathing movements was not significantly different from prefasting values in either uninfused or glucose-infused groups of fetuses (Fig. 1). In the fetus in which glucose infusion failed, the incidence of fetal breathing movements was maintained at a normal value (38.2%) at 24 hours of fasting but had fallen to a value (13.7%) similar to that in the uninfused, hypoglycemic fetuses at the end of the fast (Fig. 1).

In contrast to earlier findings,[12] there was no apparent change in the amplitude of fetal breathing movements during maternal fasting in the hypoglycemic fetuses (Fig. 1). Nor was there any significant change in amplitude in the glucose-infused fetuses during the 48-hour period of maternal fasting (Fig. 1).

Relationship between fetal breathing movements and plasma concentrations of glucose and PGE. When the data from all the fetuses were combined, irrespective of the day or type of treatment, there was a significant positive correlation between the incidence of fetal breathing movements and the arterial plasma glucose concentration in the individual fetuses (Fig. 2). No significant correlation was observed between the incidence of fetal breathing movements and the fetal plasma PGE level ($r = -0.120$, $n = 32$, $p > 0.05$) or between the latter values and the fetal arterial concentration of plasma glucose ($r = -0.166$, $n = 32$, $p > 0.05$).

Comment

This study demonstrates that the reduction in the incidence of fetal breathing movements observed during maternal fasting is due primarily to the fall in glucose concentration in the fetal plasma. The degree of fetal hypoglycemia produced by fasting and the reduction in breathing activity observed in the hypoglycemic fetuses in the current study were similar to those reported previously, as were the increments in plasma PGE.[3, 4, 6, 12] When fetal normoglycemia was maintained during the fast by fetal glucose infusion, there was no reduction in the incidence of fetal breathing movements in spite of an increase in fetal plasma PGE similar to that seen in the hypoglycemic fetuses. These observations indicate that, contrary to previous suggestions,[6] PGE is not directly involved in regulating fetal breathing movements during maternal fasting, although any effects of PGE may have been obscured by glucose administration in the fetus.

Role of prostaglandins. In other circumstances prostaglandins, including PGE, are known to affect the incidence of fetal breathing movements in the sheep.[7] Reducing the circulating prostaglandin levels in the fetus by treatment with prostaglandin synthetase inhibitors (aspirin, indomethacin, meclofenamate) leads to an increased incidence of fetal breathing movements, which can be restored to its normal value by PGE infusion.[7, 10] Intrafetal infusion of prostaglandin, particularly PGE, to levels similar to those seen during labor also causes a rapid reduction in the normal incidence of fetal breathing movements.[10] In the current study the percentage increase in fetal plasma PGE observed during fasting was smaller than that during infusions of PGE sufficient to reduce the incidence of fetal breathing movements.[10] Furthermore, fetal plasma PGE concentrations observed at the end of the fast in this study were less than those measured during labor.[12] These observations suggest that there may be a critical circulating concentration of PGE above which inhibition of fetal breathing movements occurs. The finding that the relationship between the incidence of fetal breathing movements and the dose of PGE_2 infused into meclofenamate-treated fetuses is not linear supports this suggestion.[10]

Previous studies have shown that the concentrations of plasma glucose and PGE are both significant influ-

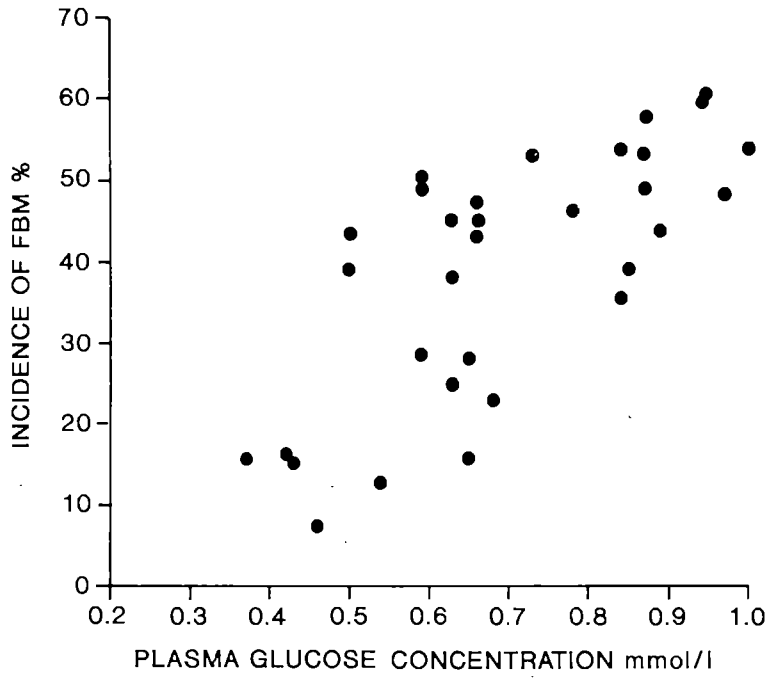

Fig. 2. Relationship between incidence of fetal breathing movement (FBM) and arterial concentration of plasma glucose in individual fetuses, irrespective of their nutritional state. $y = 62.5x - 4.6$, $n = 32$, $r = 0.716$, $p < 0.01$.

ences on the incidence of fetal breathing movements in the sheep fetus after 130 days of gestation.[10,12] Under normal nutritional conditions, PGE may be the more important factor physiologically as fetal PGE levels rise toward term, whereas fetal plasma glucose levels vary very little during late gestation in well-fed animals.[17,18] However, even under these conditions, PGE is unlikely to be the only influence on fetal breathing movements because the decrease in breathing activity observed toward term still occurs when the normal prepartum increase in fetal plasma PGE is abolished by meclofenamate treatment.[19] Certainly in the current study fasting-induced rises in plasma PGE did not inhibit fetal breathing activity when they were accompanied by fetal normoglycemia, which suggests that plasma glucose may be the more important factor regulating fetal breathing movements during adverse nutritional conditions.

Central mechanisms. The mechanism whereby hypoglycemia reduces the incidence of fetal breathing movements is still unclear but may involve changes in cerebral metabolism and acid-base balance.[2,3,7] Fetal hypoglycemia, induced by insulin administration, reduces cerebral glucose utilization and leads to changes in the acid-base status of the peripheral circulation.[5,6] On the other hand, hypoglycemia induced by fasting has no apparent effect on cerebral glucose consumption, although there is a reduction in sagittal sinus P_{CO_2} and H^+ ion levels, which suggests that less carbon dioxide is being produced by the fetal brain under these circumstances.[3] Certainly, when glucose is infused into hypoglycemic fetuses of fasted ewes, there is a rise in cerebral glucose utilization that is accompanied by central acidosis and an increase in fetal breathing activity.[3] These observations suggest that fetal glycemia may alter fetal breathing activity by changing the chemical environment of the central chemoreceptors. These receptors are responsive in utero and known to be active in the control of ovine fetal breathing movements during late gestation.[20,21]

It has also been postulated that central chemoreceptors mediate the respiratory effects of prostaglandins in the fetus.[7,21,22] Infusions of prostaglandin synthetase inhibitors produce central acidosis in the sheep fetus, whereas PGE infusion may cause cerebral vasodilatation and lead to central alkalosis as a consequence.[22] Changes in the fetal concentrations of PGE and glucose may therefore act on fetal breathing movements through a common pathway, which, in the case of maternal fasting, would have additive effects at the chemoreceptors and lead to a reduced incidence of fetal breathing movements. However, the effect of the increment in PGE induced by fasting must be relatively small, as no change in fetal breathing movements was observed in the current study when fetal PGE levels increased in the absence of any change in fetal glucose concentrations. Whatever the central mechanisms involved, these findings show that the respiratory effects of fetal hypoglycemia, induced by fasting, are not mediated through changes in fetal plasma PGE.

Uteroplacental prostaglandin synthesis. Hypoglycemia in either the mother or fetus appears to be a potent stimulus to prostaglandin synthesis in the pregnant ewe. When maternal glucose levels fall during fasting or insulin administration, there are increases in the maternal concentrations of PGE and 13,14-dihydro-15-keto-prostaglandin $F_{2\alpha}$ (PGFM), the main metabolite of prostaglandin $F_{2\alpha}$.[11-13] Similarly, when the fetus becomes hypoglycemic, its prostaglandin levels rise even when there is no change in maternal glycemia.[11-13] The most likely source of this PG is the uteroplacental tissues, because there are significant arteriovenous concentration differences in PG across both sides of the ovine placenta.[11, 12, 23] Furthermore, these concentration differences across the uterine circulation widen during hypoglycemia.[11-13]

The present finding that fetal plasma PGE levels increased during fasting in both twins, irrespective of their glucose concentrations, appears to suggest that maternal glucose levels may have the more dominant role in regulating uteroplacental PG production. However, when glucose is infused into single fetuses to maintain normoglycemia during maternal fasting, no rise in maternal plasma PGFM occurs in spite of sustained hypoglycemia in the ewe.[24] Although neither $PGF_{2\alpha}$ nor PGE was measured in this study,[24] these findings suggest that uteroplacental prostaglandin production can be inhibited by glucose infusion into a single fetus. However, infusion of glucose into one of a pair of fetuses, even at rates higher than its normal use, clearly is not sufficient to overcome the combined effects of hypoglycemia in its mother and uninfused twin. Increased PGE production therefore occurs in the uteroplacental tissues of the uninfused twin and leads directly to elevated PGE levels in the ewe and hypoglycemic fetus. Because PGE crosses the ovine placenta[25] and maternal PGE concentrations are invariably higher than those in the fetus, the high plasma PGE level found during fasting in the normoglycemic fetus could be due merely to transplacental passage of PGE down its concentration gradient from the ewe.

The way in which glycemia affects prostaglandin synthesis remains unknown, although the results of this and previous studies indicate that the rate of placental glucose consumption is probably a key factor in determining prostaglandin production by the uteroplacental tissues.[12, 24] However, further studies of uteroplacental prostaglandin output in different nutritional conditions are required before the role of placental glucose consumption and the relative importance of fetal and maternal glucose in controlling prostaglandin synthesis can be ascertained fully. It may be that changes in the availability of other metabolites such as fatty acids, which accompany the changes in glycemia induced by fasting, are also important in determining prostaglandin production in utero.[11]

We thank Mrs. D. Houlton and Mr. P. Hughes for their help during surgery and sampling, Mr. I. Cooper and Mr. D. Clarke for their care of the animals, and Miss L. Mundy and Miss D. Brouwer for their assistance with the biochemical analyses.

Bound volumes available to subscribers

Bound volumes of the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY are available to subscribers (only) for the 1992 issues from the Publisher, at a cost of $68.00 for domestic, $95.76 for Canada, and $91.00 for international for Vol. 166 (January-June) and Vol. 167 (July-December). Shipping charges are included. Each bound volume contains a subject and author index and all advertising is removed. Copies are shipped within 60 days after publication of the last issue in the volume. The binding is durable buckram with the JOURNAL name, volume number, and year stamped in gold on the spine. *Payment must accompany all orders.* Contact Mosby–Year Book, Inc., Subscription Services, 11830 Westline Industrial Drive, St. Louis, MO 63146-3318, USA; phone (800) 325-4177, ext. 4351, or (314) 453-4351.

Subscriptions must be in force to qualify. Bound volumes are not available in place of a regular JOURNAL subscription.

Human vaginal leukocytes and the effects of vaginal fluid on lymphocyte and macrophage defense functions

Josaph A. Hill, MD, and Deborah J. Anderson, PhD
Boston, Massachusetts

OBJECTIVES: The purpose of this study was to quantify, characterize, and further define the role of vaginal white blood cells in defense mechanisms and human immunodeficiency virus infection.
STUDY DESIGN: Vaginal lavages were obtained from five hea thy women throughout three menstrual cycles. Lymphocyte subpopulations, macrophages, and granulccytes were characterized and quantified by an immunohistologic technique. Vaginal lavage fluid was addec to peripheral blood mononuclear cells, and effects on cell viability, lymphocyte proliferation, macrophage phagocytosis, and expression of various cell surface molecules critical to immunologic functions were assessed. Data were analyzed by Student's *t* test.
RESULTS: Few lymphocytes were found at any stage of the menstrual cycle; however, granulocytes and macrophages were abundant at menstruation and present at low levels through the proliferative phase. Vaginal lavage fluid collected during menses, at midcycle, and after coitus suppressed mitogen-induced lymphocyte proliferation but had no effect on surface expression of human leukocyte antigen or CD4 antigens, or on macrophage function. Likewise, low pH (<5.0) medium significantly inhibited lymphocyte proliferation but had no effect on macrophage phagocytosis. The spermicide nonoxynol 9 was toxic to both lymphocytes and macrophages.
CONCLUSION: White blood cells, including lymphocytes and macrophages, are infrequently present in cervicovaginal secretions of healthy women except during menses; the vaginal environment may effect their function. (Am J Obstet Gynecol 1992;166:720-6.)

Key words: Vagina, lymphocyte, macrophage, immune defense, human immunodeficiency virus type 1

Vaginal fluid is primarily derived from cervical secretions, exfoliated epithelial cells, bacterial products, and plasma transudation through the vaginal mucosa. Uterine, oviductal, follicular, and peritoneal fluid may also contribute.[1] Sexually communicable pathogens are transmitted through this vaginal milieu. A first line of defense is the mucosal secretory immune system of the cervix, which is capable of producing abundant amounts of secretory immunoglobulin A.[2] Cellular mechanisms important in host defense against pathogenic bacteria and viruses in the vagina include cytotoxic T-cell, natural killer cell, macrophage, and granulocyte-mediated defense mechanisms.[3, 4] This study was performed to characterize and quantitate lymphocytes and phagocytic cells in the vaginal environment and to determine the effects of lavage fluids on lymphocyte proliferation, macrophage phagocytosis, cell viability, and the expression of cell surface molecules on lymphocytes and macrophages, which are important in immunologic functions.

Material and methods

Vaginal lavage fluid collection. Five healthy women of reproductive age (range 24 to 37 years) volunteered for the study. Three were in monogamouos sexual relationships and were taking oral contraceptives or using barrier methods of contraception. The other two women were sexually inactive and were not using any method of contraception. Vaginal lavage fluids were obtained at weekly intervals through three consecutive menstrual cycles. Women collected their own samples with an adapted 20 ml syringe (extra holes drilled at end for ease in aspiration). The syringe was filled with sterile Hanks' balanced salt solution and was inserted into the vagina with the woman in a supine position. The solution was expelled and drawn into the syringe

three times, then emptied from the syringe into a 50 ml sterile test tube and delivered to the laboratory within 1 hour of collection. Samples containing <15 ml of fluid were not included in the study.

Vaginal lavage fluid preparation. Vaginal lavage fluids were centrifuged at 600 *g* for 10 minutes. The supernatant was filtered through a 0.22 μm Millex filter (Millipore Corp., Bedford, Mass.) and aliquots were stored at −70° C. For some experiments unfiltered aliquots of supernatant were incubated at 37° C overnight to promote growth of vaginal flora. The cell pellet was resuspended in 1 ml phosphate-buffered saline solution and 20 μl was transferred to a hemocytometer where cells of white blood cell morphologic type and size (5 to 15 μm) were counted. Cell viability was assessed by trypan blue exclusion. A smear of the cell suspension was made on a glass microscope slide and stained with eosin-thiazine (Hemacolor, EM Diagnostics, Gibbstown, N.J.).

In those patients with $>2 \times 10^4$ white blood cells per sample, cell smears were made on Teflon-coated slides for immunohistologic assessment of white blood cells subpopulations as previously described.[5]

Monoclonal antibodies. Various monoclonal antibodies to white blood cells subpopulations were used in the immunoperoxidase studies: pan-leukocyte (anti-HLe-1, Becton Dickinson, Mountain View, Calif.), cytotoxic/suppressor T lymphocytes (Leu-2a, Becton Dickinson), helper/inducer T lymphocytes and some monocytes/macrophages (Leu 3a + b, Becton Dickinson), pan-T cell (Leu 4a + 5b, Becton Dickinson), macrophages (Dako-macrophage, Dako Corporation, Santa Barbara, Calif.), B lymphocytes, (Pan-B, Dako Corp.), and natural killer cells (NKH-1, Becton Dickinson).

The following monoclonal antibodies to immunologically relevant lymphocyte/macrophage surface antigens were used in radioimmunoassay studies of antigen modulation by soluble vaginal fluid factors: HLA-A,B,C, HLA-DR, interleukin-2 receptor (Il-2R), and anti-CD4 (Leu 3a+b); all of these were from Becton Dickinson.

Immunoperoxidase technique. A streptavidin-biotin-peroxidase system (Histostain—SP kit, Zymed Laboratories, San Francisco) was used as previously described.[5] Briefly, acetone-fixed eight-spot Teflon slides were thawed and air-dried. Nonspecific binding sites were blocked by nonimmune rabbit serum (10 minutes). Appropriately diluted monoclonal antibodies (listed previously) or phosphate-buffered saline solution (negative control) were incubated on individual spots of eight-spot slides for 30 minutes at 37° C. Slides were washed, and a Histostain-SP kit with a biotinylated secondary antibody was used to visualize bound antibodies. Slides were counterstained with hematoxylin, and coverslips were mounted with glycerol–polyvinyl alcohol aqueous mounting medium.

Phagocytosis. Macrophage phagocytosis of fluorescent carboxylate microspheres (Polysciences, Inc., Warrington, Pa.) was determined as previously described.[6] Briefly, human peripheral blood mononuclear cells were isolated by Ficoll-Hypaque centrifugation, washed three times, and resuspended at a concentration of 1×10^6 cells per milliliter in RPMI 1640 tissue culture medium buffered with sodium bicarbonate and containing 10% fetal calf serum, 10 mmol/L L-glutamine, and 10 mmol/L penicillin-streptomycin (GIBCO, Grand Island, N.Y.). Macrophages were obtained by incubation of a suspension of 1 ml of peripheral blood mononuclear cells on 12 mm round glass coverslips (Rochester Scientific Co., Inc., Rochester, N.Y.) in 24-well tissue culture plates (Falcon, Becton Dickinson, Lincoln Park, N.J.) for 1 hour at 37° C followed by removal of nonadherent cells by gentle pipetting and aspiration. Macrophages were cultured overnight in wells containing 1 ml of vaginal lavage fluid, 10% seminal plasma, 10% saliva, 1% nonoxynol 9 ($C_{33}H_{60}O_{10}$; Ortho Pharmaceutical Corporation, Raritan, N.J.), or Hanks' balanced salt solution (control) and 1 ml tissue culture medium. Microspheres were added and incubation was continued for 4 hours, after which the cells were vigorously washed to remove nonadherent microspheres and recultured for an additional hour in tissue culture medium to reduce background binding of microspheres to cells. The coverslips with attached cells were rinsed in Hanks' balanced salt solution, fixed in acetone for 10 minutes, and then placed cell side up on glass slides. Coverslips (24 × 50 mm) were mounted over cell monolayers with 80% glycerol and phosphate-buffered saline solution. Macrophage phagocytosis (percent of macrophages with more than five intracellular microspheres) was assessed on a Zeiss (Carl Zeiss, Inc., Thornwood, N.Y.) phase/epifluorescence microscope.

Radioimmunoassay. Human peripheral blood mononuclear cells (7×10^6) were incubated in 1 ml undiluted vaginal lavage fluid, in 10% or 1% seminal plasma, 10% saliva, or 0.01% nonoxynol-9 diluted in Hanks' balanced salt solution, or in Hanks' balanced salt solution alone at 37° C for 1 hour. The cells were then washed three times in RPMI 1640 medium and resuspended at a concentration of 2×10^6 cells per milliliter in RPMI medium containing 1% bovine serum albumin (washing solution); 0.2 ml of cell suspension was than added in triplicate to individual wells of 96-well, round-bottom microtiter plates (Linbro Division, Flow Laboratories, Inc., McLean, Va.). Cells were pelleted by centrifugation (500*g* for 5 minutes), the supernatant was removed from each well, and 0.02 ml of appropriately diluted monoclonal antibodies was added

to the wells. After 1 hour of incubation at 4° C, the cells were washed three times and 200,000 counts/min of iodine 125–labeled rabbit antimouse immunoglobulin G (New England Nuclear, Boston) was added and incubated for an additional hour; then the cells were washed five times and counted in a γ-counter.

Lymphocyte proliferation. Lymphocyte proliferation was determined as previously described.[7] Briefly, peripheral blood mononuclear cells were adjusted to a concentration of 2.5×10^6 cells per milliliter in tissue culture medium. Cultures were set up in quadruplicate in 96-well tissue culture plates with each well containing 2.5×10^5 cells in 0.1 ml tissue culture medium; either 0.09 ml undiluted vaginal lavage fluid, 10% or 1% seminal plasma, 10% saliva, 0.01% nonoxynol-9, or Hanks' balanced salt solution; and 0.01 ml concanavalin A (Sigma Chemical Co., St. Louis; 30 gm/ml) or tissue culture medium. For the study of effects of pH on lymphocyte proliferation, tissue culture medium was made with RPMI 1640 that did not contain sodium bicarbonate and was pH adjusted with 0.1 mol/L phosphate buffer (pH range 3 to 12). Cultures were incubated for 72 hours at 37° C in a humidified atmosphere of 5% carbon dioxide and 95% air.

Lymphocyte proliferation was assessed by adding 0.5 μCi of [^{3}H]thymidine (13.1 Ci/mmol, New England Nuclear) 8 hours before harvesting with a MASH II (Microbiological Associates, Los Angeles) automatic sample harvester. Peripheral blood mononuclear cell viability was assessed before harvesting by trypan blue exclusion. Cells on dried glass fiber filter paper disks were suspended in 2 ml Betafluor scintillation cocktail (National Diagnostics, Somerville, N.J.), and radioactivity was measured in a Beckman liquid scintillation counter (Beckman Instruments, Inc., Fullerton, Calif.) (efficacy of the system 45%).

Statistical analysis. The unpaired Student t test and analysis of variance were used to calculate the significance of differences between test solutions. Statistical significance was assumed when the null hypothesis could be rejected with reasonable assurance ($p < 0.05$).

Results

Vaginal samples collected during menses and the proliferative phase of the menstrual cycle from healthy women contained numerous macrophages and granulocytes but few T lymphocytes, B lymphocytes, or plasma cells (Table I). Fewer than 10^4 leukocytes were found in samples from the periovulatory and secretory phases of the menstrual cycle, except in two women during one cycle each in which a symptomatic vaginal yeast infection was noted at midcycle and during the secretory phase. In these samples 2 to 3 $\times 10^5$ vaginal white blood cells were recovered; the majority of cells were macrophages and granulocytes, although $CD4^+$ lymphocytes and interleukin-2 $receptor^+$ lymphocytes were also observed. Few ($<10^4$) $CD8^+$ cytotoxic/suppressor T lymphocytes and no B lymphocytes were found. Within 1 week of therapy with fungicidal cream, hyphae and white blood cells were no longer observed in the vaginal lavage fluids.

Peripheral blood mononuclear cells were used to study the effects of vaginal lavage fluids on cellular defense functions because insufficient numbers of vaginal cells could be recovered for such studies. Vaginal lavage fluids collected during various phases of the menstrual cycle did not adversely affect peripheral blood lymphocyte viability as measured by trypan blue exclusion after a 2-hour incubation. Alteration of pH in tissue culture medium by replacement of bicarbonate buffer with 0.1 mol/L phosphate buffer (pH range 3 to 12) likewise did not affect leukocyte viability after 2 hours of culture. Cell viability was also unaffected by 10% seminal plasma, 10% saliva, or postcoital vaginal secretions without nonoxynol-9. The vaginal spermicide nonoxynol-9, however, when tested alone at concentrations ranging from 10% to 0.01% or when present in certain postcoital vaginal lavages, significantly affected peripheral blood leukocyte viability after 2 hours of exposure (<10% viable).

The function of peripheral blood–derived macrophages, as assessed by the ability of adherent cells to phagocytose fluorescent latex beads, was not signifi-

cantly affected by vaginal lavage fluid, 10% seminal plasma, or saliva. Furthermore, macrophages from vaginal lavage fluids collected at both menstrual and periovulatory phases of the cycle could adhere to plastic and phagocytose latex beads. Likewise, macrophage phagocytosis was not significantly affected by low pH conditions. However, neither adherence nor phagocytosis was observed in macrophage cultures exposed to 0.01% nonoxynol-9 or postcoital vaginal lavage fluids containing nonoxynol-9, presumably because of the disruptive effect of this compound on cell membranes (data not shown).

Expression of class I (HLA-A,B,C) and class II (HLA-DR) major histocompatibility antigens and the CD4 antigen (human immunodeficiency virus type 1, [HIV-1] receptor) on peripheral blood mononuclear cells was not affected by exposure to precoital or postcoital vaginal lavage fluids, seminal plasma, or saliva. Nonoxynol-9, when tested alone at a concentration of 1%, significantly affected surface antigen expression of all three markers; however, various postcoital vaginal lavage samples containing nonoxynol-9 had no effect on surface antigen expression (Table II).

Data showing effects of vaginal lavage fluid on lymphocyte proliferation are presented in Table III. Vaginal lavage fluids collected during the periovulatory and menstrual phases significantly inhibited lymphocyte proliferation. Vaginal lavage fluid collected and processed within 4 hours after coitus also had a very strong suppressive effect on lymphocyte proliferation, presumably because of the presence of seminal plasma, which has a strong immunosuppressive effect in these assay systems.[8] Nonoxynol-9 at a 0.01% concentration almost completely abolished lymphocyte proliferation, and postcoital samples containing nonoxynol-9 were more immunosuppressive than postcoital samples without nonoxynol-9 (48% vs 63% of control, $p < 0.01$). Saliva at a final concentration of 10% had no effect on lymphocyte proliferation. Aliquots of vaginal lavage fluids that were incubated overnight at 37° C before use had an increased inhibitory effect on lymphocyte proliferation (Table III), suggesting that vaginal flora may contribute to the immunosuppressive effect. Lymphocyte proliferation was significantly reduced in pH-controlled medium when the pH was <5 (Fig. 1).

Comment

Vaginal protective mechanisms against pathogens include mucosal secretory immunity, cyclic menses, bioactive reproductive secretions, low pH, and metabolic

products of commensal organisms.[9-12] Cellular mechanisms of host defense in the vagina have not been adequately described nor have white blood cells in the healthy human vagina been systematically studied in relation to the menstrual cycle. In this study vaginal lavage fluid was collected in five women on the first day of menses and thereafter every 7 days for three consecutive menstrual cycles. A total of 60 samples were studied. Our findings indicate that in healthy women appreciable numbers of white blood cells ($>2 \times 10^4$ white blood cells per milliliter) are recovered from the vagina only during menstruation and the proliferative phase of the menstrual cycle. The relatively low number of white blood cells ($6.5 \times 10^4 \pm 8.8 \times 10^3$) that were recovered from menstrual lavage fluids was not surprising because on average <80 ml of blood is lost during menses, and this occurs over a 3- to 5-day duration.[13] Menstrual lavage white blood cells consisted primarily of granulocytes and macrophages, which are abundant in the human endometrium.[14] Few T lymphocytes and almost no B lymphocytes were observed even in menstrual lavages. Some of the lymphocytes present, however, appeared to be activated as determined by interleukin-2 receptor positivity. The low numbers of white blood cells (primarily granulocytes and macrophages) observed in proliferative phase lavage fluid may represent residual leukocytes within the vagina after menses. We recently detected asymptomatic cervical-vaginal leukocytosis ($>10^4$ white blood cells) in 20% of healthy patients with infertility at mid-

cycle in an artifical insemination program and found an association between leukocytosis and cervical factor infertility.[15]

There was no discernible difference in vaginal cell counts or effects of lavage fluids in immune function assays between the women in this study. However, the small sample size precludes a definitive statement regarding effects of contraceptives or sexual activity on these parameters. To minimize the variable of acute white blood cells infiltration after insemination as a result of chemotactic factors and leukocytes in human semen,[16, 17] routine vaginal samples were collected after at least 48 hours of sexual abstinence. Postcoital samples were only tested in a few functional assays.

Cell-free vaginal lavage fluid from the menstrual and periovulatory phases of the cycle significantly inhibited concanavalin A–induced lymphocyte proliferation. Immunosuppressive effects of vaginal lavage fluids collected during menses and in the periovulatory phase of the menstrual cycle may indicate an attenuation of normal immune surveillance and enhanced susceptibility to infection during these times. Reports of an increased prevalence of endometritis-salpingitis and peritonitis as a result of *Neisseria gonorrhoeae* at the time of menses[18] support this speculation. Immunosuppression during the periovulatory phase may also be a mechanism for attenuation of a woman's immune response to spermatozoa. Data from this study indicate that lymphocyte proliferation is sensitive to low pH. The usual pH of the vagina in women of reproductive age is approximately 4; the lowest pH values are detected at midcycle during the periovulatory phase.[1] Therefore the low pH environment of the vagina may normally affect lymphocyte function, especially at midcycle. In our study vaginal samples were mixed with biocarbonate-buffered tissue culture medium (pH 7.4) and therefore were no longer at their physiologic pH. Thus pH was not the factor responsible for the immunosuppressive effect of vaginal lavage fluid obtained during mensturation and the proliferative phase of the cycle. In addition to organic acids that lower the vaginal pH, other immunosuppressive components have been described to be present in vaginal secretions.[19]

Data from this study may also have relevance to better defining mechanisms of sexual transmission of the HIV-1.[20] $CD4^+$ lymphocytes and macrophages can host HIV-1.[20] Epidemiologic studies have not revealed an increased risk of human immunodeficiency virus transmission during one phase of the menstrual cycle as opposed to another; however, traumatic bleeding during intercourse has been shown to be a risk factor for male-to-female human immunodeficiency virus transmission.[21] Our finding of few $CD4^+$ lymphocytes and macrophages in vaginal fluid of healthy women throughout the menstrual cycle supports this epidemiologic observation and suggests that healthy women may have a low human immunodeficiency virus infection rate because of low levels of HIV-1 target cells in the vagina. Vaginal pH may also affect HIV-1 transmission. In this study we demonstrated that T lymphocyte activation is inhibited by low pH, a condition normally found in the vagina. Lymphocyte activation is associated with the production of HIV-1.[22] Free HIV-1 is also rapidly inactivated by low pH.[23] Vaginitis often causes an elevation in vaginal pH.[24] Therefore women with vaginal infections may be at higher risk for HIV-1 acquisition and transmission because of two factors: increased numbers of infected-infectable cells and a more hospitable pH for infection.

Cell viability, macrophage phagocytosis, and surface expression of class I and class II major histocompatibility antigens, interleukin-2 receptor, and CD4 antigens were unaffected by vaginal lavage fluids except in the presence of the spermicide, nonoxynol-9, which was toxic to lymphocytes and macrophages. This is not surprising, because this compound is a detergent and disrupts the cell plasma membranes. Our finding that nonoxynol-9 interfered with the detection of cell-associated major histocompatibility complexes and CD4 surface antigens by radioimmunoassay when added directly to peripheral blood lymphocyte cultures at a concentration of 0.01%, but not when present in postcoital vaginal lavage fluid, probably reflect differences in spermicide concentration. Nonoxynol-9 inhibits HIV-1 replication in vitro[25] and in our study was demonstrated to be toxic to HIV-1 host cells ($CD4^+$ lymphocytes and macrophages) and to affect expression of the HIV-1 receptor CD4. Therefore vaginal application of high concentrations of nonoxynol-9 may significantly interfere with certain mechanisms underlying the sexual transmission of human immunodeficiency virus.

In conclusion, relatively few white blood cells were recovered from vaginal lavage fluid of healthy women except at menses when a moderate number of granulocytes and macrophages were observed. Lymphocyte but not macrophage defense functions were inhibited by low pH, which is the normal physiologic condition of the vagina, and cell-free vaginal lavage fluid collected during menses and at midcycle inhibited lymphocyte activation and proliferation. These observations suggest that lymphocyte activity may be inhibited at certain stages of the cycle but that phagocytes probably play an active role in host defense in the normal vaginal environment. Furthermore, the principal spermicide, nonoxynol-9, was toxic to both lymphocytes and macrophages and significantly inhibited their function. Further studies are needed to characterize macrophage, dendritic cell, and lymphocyte populations in the vag-

inal epithelium and regional lymph nodes that also may play a role in host defense and in HIV-1 transmission. Further work is also needed to determine what effects various infections have on the vaginal environment and the recruitment of white blood cells to this site.

Effect of endothelium-derived relaxing factor inhibition on the umbilical-placental circulation in fetal lambs in utero

Jia-Kan Chang, MD,[a] Christine Roman, BS,[b] and Michael A. Heymann, MD[b]
Taipei, Taiwan, and San Francisco, California

OBJECTIVE: The purpose of this study was to examine whether basal endothelium-derived relaxing factor release contributes to regulation of resting umbilical-placental vascular resistance.
STUDY DESIGN: Because N^{ω}-nitro-L-arginine selectively inhibits the synthesis of nitric oxide, a major endothelium-derived relaxing factor, we investigated the effects of N^{ω}-nitro-L-arginine on umbilical-placental vascular resistance in 10 fetal lambs in utero. We inserted catheters and fitted an umbilical artery electromagnetic flow transducer around the common umbilical artery to measure umbilical blood flow and catheterized the left umbilical arterial hypogastric branch to allow selective umbilical-placental infusion (60 minutes) of pH-matched saline solution (control) or N^{ω}-nitro-L-arginine.
RESULTS: In seven normal fetal lambs, N^{ω}-nitro-L-arginine increased umbilical-placental vascular resistance and arterial pressures and decreased umbilical blood flow ($p < 0.05$); percentage changes from baseline were 50.8% ± 18.3%, 40.3% ± 8.1%, and −9.9% ± 6.4%, respectively. In three mildly asphyxiated (compromised) fetuses, these changes were 101.4% ± 28.7%, 31.2% ± 4.8%, and −37.9% ± 12.0%.
CONCLUSION: These data support the hypothesis that the basal endothelium-derived relaxing factor release plays a role in regulating resting umbilical-placental vascular resistance. (AM J OBSTET GYNECOL 1992;166:727-34.)

Key words: Nitric oxide, N^{ω}-nitro-L-arginine, placental circulation, umbilical vascular tone, umbilical vascular resistance

The umbilical circulation receives about 40% of the combined ventricular output in near-term fetal lambs.[1] Normal fetal growth and viability depend on the umbilical circulation for the supply of nutrients and exchange of gases. Any impairment in this circulation may increase the possibilities of growth retardation, fetal distress, and intrauterine fetal death.

The umbilical-placental vascular bed represents a vast network of blood vessels without neural supply, so that umbilical blood flow is predominantly controlled by general circulatory effects, such as systemic blood pressure, or locally produced humoral vasoactive substances.[2] Several vasoactive substances, including bradykinin, prostacyclin, and histamine, have been shown to affect the umbilical circulation.[3-5] However, relatively little is known about the effects of another potent vasoactive substance, endothelium-derived relaxing factor (EDRF), on the umbilical circulation.[6-9] Recently, it has been proposed that EDRF, or one of its components, could be nitric oxide, originating from endothelial cell metabolism of L-arginine.[10, 11] EDRF plays an important role in regulating pulmonary and systemic vascular resistances by stimulating soluble guanylate cyclase and subsequently increasing guanosine 3′,5′-cyclic monophosphate levels in adjacent vascular smooth muscle cells to elicit a vasorelaxant effect.[10-13] We therefore considered that EDRF could also play an important role in regulating umbilical vascular tone. To test this hypothesis, we used N^{ω}-nitro-L-arginine, which has been demonstrated to be a potent inhibitor of the enzymatic synthesis of nitric oxide from L-arginine.[14, 15] After an infusion of N^{ω}-nitro-L-arginine directly into the umbilical circulation through a hypogastric branch of the left umbilical artery, we evaluated the hemodynamic changes in fetal lambs in utero to determine whether basal production and release of EDRF plays a role in maintaining the low vascular tone in the intact umbilical-placental circulation.

Material and methods

Surgical preparation. Ten mixed Western fetal sheep of 133 to 137 days' gestation (term 145 days) were studied. Before surgery, the ewe fasted for 24 hours and water was withheld overnight. Low epidural anesthesia was achieved with 4 ml 1% tetracaine hydrochloride. To maintain light sedation, 50 to 100 mg ketamine hydrochloride was administered frequently. For adequate analgesia the fetus and ewe also received local anesthesia with 2% lidocaine hydrochloride for each

skin incision. Polyvinyl catheters were inserted into the maternal pedal artery and vein to monitor blood gases and pressure and to administer 500 to 1000 ml 10% dextrose in 0.9% saline solution at a rate of 3 to 5 ml/min during surgery and to administer antibiotics subsequently.

With aseptic techniques, a midline incision was made and the pregnant horn of the uterus was palpated and exposed. On opening the uterus, two 3.5F multiple-side-hole polyvinyl catheters were introduced into a distal cotyledonary branch of the umbilical vein and each was advanced to one of the main umbilical veins. Then the fetal hind limbs were exteriorized through the same uterine incision, and polyvinyl catheters were inserted into one pedal vein and artery in each hind limb and advanced to lie in the inferior vena cava and distal abdominal aorta, respectively. The hind limbs were extracted further to expose the lower abdomen and left flank. Then, as we have described in detail,[16] a left flank incision was made parallel to the spine, extending 3 to 4 cm cephalad from the left iliac crest. After blunt retroperitoneal dissection, the lower abdominal aorta, left iliac artery, common umbilical artery, left umbilical artery, and hypogastric (posterior pelvic) branch of the left umbilical artery were visualized clearly. The hypogastric branch was catheterized with a small polyvinyl catheter (inner diameter 0.030 inch). The catheter's tip was positioned near the origin of the left umbilical artery from the common umbilical artery. A precalibrated electromagnetic flow transducer of appropriate size was fitted around the common umbilical artery to measure umbilical blood flow.[16] The incision was closed in layers, and the fetus was returned to the uterus. A 12F polyvinyl catheter was placed in the amniotic cavity before the uterine incision was closed, and 100 mg gentamicin sulfate and 1,000,000 U penicillin G potassium were administered into the amniotic cavity. Warmed normal saline-solution was infused to replace lost amniotic fluid; then the uterine incision was closed and oversewn to prevent leakage of amniotic fluid.

All vascular catheters were flushed with 1 ml heparin sodium solution (1000 U/ml) to keep them patent and then sealed with special plugs. The catheters and transducer cable were exteriorized through the abdomen to a Teflon cloth pouch on the left flank of ewe. The labarotomy was closed in layers. One hundred milligrams of gentamicin sulfate and 1,000,000 U penicillin G potassium were administered intravenously to the ewe.

Antibiotics were administered intravenously to the ewe and into amniotic cavity daily. The preparation was approved by the Committee on Animal Research, University of California at San Francisco.

Experimental procedures. Experiments were performed on the second to fourth postoperative days with the ewe in the nonfasted state while the ewe stood quietly in a study cage with free access to alfalfa pellets and water. To determine the effects of N^{ω}-nitro-L-arginine on the umbilical circulation, two sequential series of experiments were performed in 10 fetal lambs, one during infusion of control solution (pH-matched normal saline) and the other during infusion of N^{ω}-nitro-L-arginine. We recorded the variables during four sequential steps in each animal in this order: (1) at baseline 1, (2) after control solution infusion for 1 hour, (3) at baseline 2, and (4) after N^{ω}-nitro-L-arginine infusion for 1 hour. We measured the fetal systemic arterial and venous pressures, umbilical venous pressure, umbilical blood flow, amniotic cavity pressure, heart rate, arterial blood gases and pH, hemoglobin, and oxygen saturation during each experimental condition. Before starting the infusion of either control or N^{ω}-nitro-L-arginine solution, we assured that flow and blood gases were in a steady condition for at least 30 minutes. At the end of study, positions of all catheters and the flow transducer were checked at autopsy.

Hemodynamic measurements. Strain-gauge transducers (model P23Db, Statham Instruments, Oxnard, Calif.) were used for continuous recording of aortic, umbilical venous, inferior vena caval, and amniotic fluid pressures. Mean pressure was obtained by electrical integration, and heart rate was obtained by a Beckman type 9857B cardiotachometer triggered from the arterial pressure pulse tracing. Umbilical blood flow was measured with a Statham SP 2202 electromagnetic flowmeter (frequency response flat to 100 Hz; 5% error; 2% reproducibility of flow measurement). During the study, pressures, heart rate, and umbilical blood

Table II. Hemodynamic variables before and after 60-minute infusion of normal saline solution in fetal lambs

	Before	*After*
Normal fetal lambs (n = 7)

Umbilical blood flow (ml/min/kg)	138 ± 31.6	134 ± 28.0
Δ (SAP − UVP) (mm Hg)	34.7 ± 4.2	36.0 ± 4.4
Heart rate (beats/min)	177 ± 21.6	174 ± 19.7

Values are means ± SD. Δ *(SAP − UVP)*, Difference between mean systemic arterial and umbilical venous pressures.

flow were recorded on a Beckman eight-channel Dynograph direct-writing recorder. All fetal pressures were corrected to amniotic fluid pressure as a zero reference level. Umbilical-placental vascular resistance was calculated from umbilical blood flow measured by the precalibrated electromagnetic flow transducer, and mean pressures were measured in the umbilical vein and descending aortic simultaneously. We assumed no significant difference between descending aortic and umbilical arterial pressures. Fetal blood samples were obtained from the descending aorta for measurement of pH, P_{CO_2}, and P_{O_2} (model 158 pH/blood gas analyzer, CIBA Corning, Medfield, Mass.) and of hemoglobin concentration and hemoglobin oxygen saturation (model OSM 2 hemoximeter, Radiometer, Copenhagen) during each experimental condition.

Radioactive microsphere analysis. To revalidate the accuracy of umbilical blood flow measurements by the electromagnetic transducer method, we simultaneously measured umbilical blood flow 25 times in eight fetal lambs with radionuclide-labeled microsphere injections during periods when the flowmeter was recording a steady umbilical blood flow. In all instances microspheres labeled with cobalt 57, chromium 51, gadolinium 153, indium 114, manganese 54, niobium 95, tin 113, strontium 85, and zinc 65, selected at random, were injected into the inferior vena cava over 15 to 20 seconds. A reference blood sample was withdrawn from the fetal descending aortic catheter with a constant pump rate of about 4 ml/min, beginning immediately before injection of microspheres and continuing for at least 40 seconds after the injection had been completed. The total volume of blood removed for sampling was calculated, and an equal volume of fetal or maternal blood was replaced after the microsphere study.

On completion of the last experiment, the ewe was killed with an overdose of pentobarbital. The uterus and placenta were dissected, fixed in formalin, and then carbonized. The radioactivities of placental tissue and of the reference blood samples were counted with a well-type γ-scintillation counter and a 1000-channel pulse-height analyzer (Norland, Fort Atkinson, Wis.) Umbilical blood flow was calculated as previously described.[17]

Drug preparation and dosage. Immediately before the study, Nω-nitro-L-arginine (Sigma Chemical Co., St. Louis) was dissolved in normal saline solution at a concentration of 10 mg/ml and titrated to a pH of 2.8 to 3.0 by the addition of hydrochloric acid or sodium hydroxide to prevent precipitation. Each fetal lamb was given a 30 mg bolus of Nω-nitro-L-arginine followed by a 1.5 to 2.4 mg/kg/min infusion into the hypogastric branch of the left umbilical artery for 60 minutes. Previous experience in our laboratory has shown that the effects of EDRF on the pulmonary circulation could be inhibited by a 60-minute continuous infusion of Nω-nitro-L-arginine[18] and that the effects of Nω-nitro-L-ar-

*$p < 0.05$, between baseline and infusion observation.

ginine were reversible by L-arginine infusion.[19] We followed this dosage to study the effects on the umbilical-placental circulation. To make sure that the acidity of the N$^{\omega}$-nitro-L-arginine solution alone produced no significant alterations in the fetal hemodynamic variables and blood gases, each fetal lamb received an equivalent infusion of normal saline solution that had been titrated to the same pH.

Statistical analysis. All data are presented as means ± SD. Hemodynamic variables and blood gas values during each experimental condition were compared with baseline data by paired t test. We also compared the percentage changes in variables between infusions of normal saline solution and N$^{\omega}$-nitro-L-arginine by paired t test. A probability of $p < 0.05$ was chosen to represent statistical significance.

Results

Data were obtained from 10 near-term fetal lambs in utero with a mean weight of 3.04 kg (range 2.42 to 3.58 kg). Before infusion of N$^{\omega}$-nitro-L-arginine or normal saline solution, blood gases and hemodynamic variables were checked. The fetuses were divided into two groups according to the blood gas data (Table I). Data in group 1 fetuses (normal, n = 7) were within normal limits and those in group 2 (compromised, n = 3) were not (pH < 7.3, P_{O_2} < 20 torr, P_{CO_2} > 60 torr).

After a 60-minute infusion of normal saline solution, there were no significant changes in hemodynamic variables, including umbilical blood flow and umbilical vascular resistance, in groups 1 and 2 (Tables I and II). However, selective intravascular infusion of N$^{\omega}$-nitro-L-arginine resulted in a decrease in pH and oxygen saturation in both groups and an increase in P_{CO_2} in group 1 (Table III). Hemoglobin increased in group 2.

After infusion of N$^{\omega}$-nitro-L-arginine, there were significant increases in umbilical vascular resistance, systemic arterial pressure, and the difference between mean systemic arterial and umbilical venous pressures, especially in compromised fetal lambs (Table IV). Umbilical blood flow and heart rate decreased in both groups.

We compared the percentage changes in major determinants of umbilical-placental circulation effected by infusions of normal saline solution of N$^{\omega}$-nitro-L-arginine solutions, respectively. The percentage changes of umbilical vascular resistance, systemic arterial pressure, and umbilical blood flow from baseline after infusion of N$^{\omega}$-nitro-L-arginine were 50.8% ± 18.3%, 40.3% ± 8.1%, and −9.9% ± 6.4% in group 1 and 101.4% ± 28.7%, 31.2% ± 4.8%, and −37.9% ± 12.0% in group 2. After infusion of normal saline solution, there were no significant changes. These results are shown in Figs. 1 to 3.

Measurements of umbilical blood flow derived from electromagnetic flow transducers and those derived from the radionuclide-labeled microsphere injections correlated very well (Fig. 4).

Comment

An EDRF was first reported by Furchgott and Zawadzki[20] in 1980. Over the past 10 years it has been shown that at least one form of EDRF is nitric oxide or a compound that releases nitric oxide.[10, 11] This increases guanosine 3′,5′-cyclic monophosphate concentration in vascular smooth muscle cells by activating the soluble isoenzyme form of guanylate cyclase. Subsequently, guanosine 3′,5′-cyclic monophosphate evokes the relaxant effect by activating guanosine 3′,5′-cyclic monophosphate–dependent protein kinase and dephosphorylation of myosin light chain. Hence EDRF clearly plays an important role in regulating vascular tone in the pulmonary and systemic circulations.[10-13, 21]

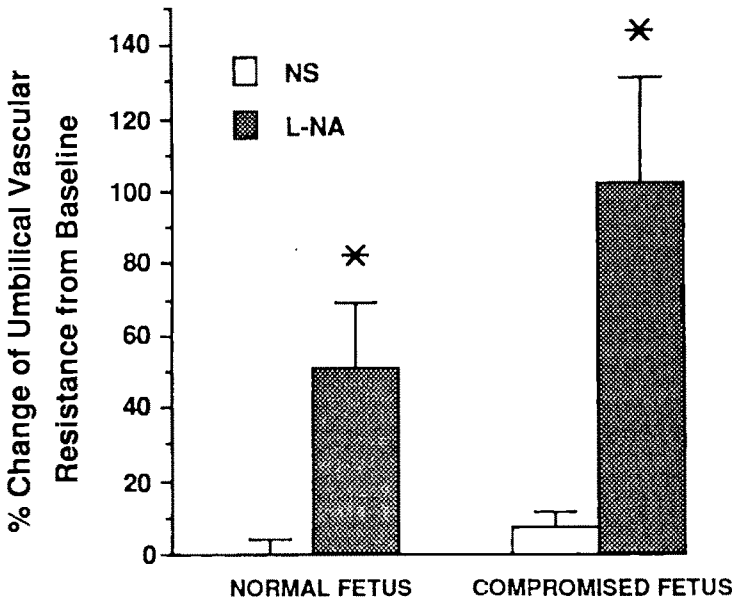

Fig. 1. Percent change in umbilical vascular resistance from baseline after infusions of normal saline solution *(NS)* and Nω-nitro-L-arginine *(L-NA)*, respectively. *Asterisk*, $p < 0.05$ Nω-nitro-L-arginine versus normal saline solution group.

However, limited and contradictory information is available on the effects of EDRF on the umbilical circulation. Van de Voorde et al.[6] reported that production of EDRF from human umbilical arteries and veins was stimulated by histamine and adenosine triphosphate but not by acetylcholine. Subsequently, Buga et al.[22] reported that EDRF could be released from human umbilical veins. However, Griggs et al.[23] found that human placental chorionic plate arteries did not have the ability to decrease vascular tone in response to either A23187 or histamine, and Monuszko et al.[24] reported that umbilical vessel rings had no relaxant response to either A23187 or acetylcholine. Therefore they considered that these vessels lacked an endothelium-dependent relaxant capability. Recently, Chaudhuri et al.[8] and Myatt et al.[7] found that the vascular tone of precontracted human umbilical or placental arteries could be reduced by glyceryl trinitrate or S-nitroso-N-acetylpenicillamine. They therefore considered that basal release of nitric oxide might contribute to regulating the low

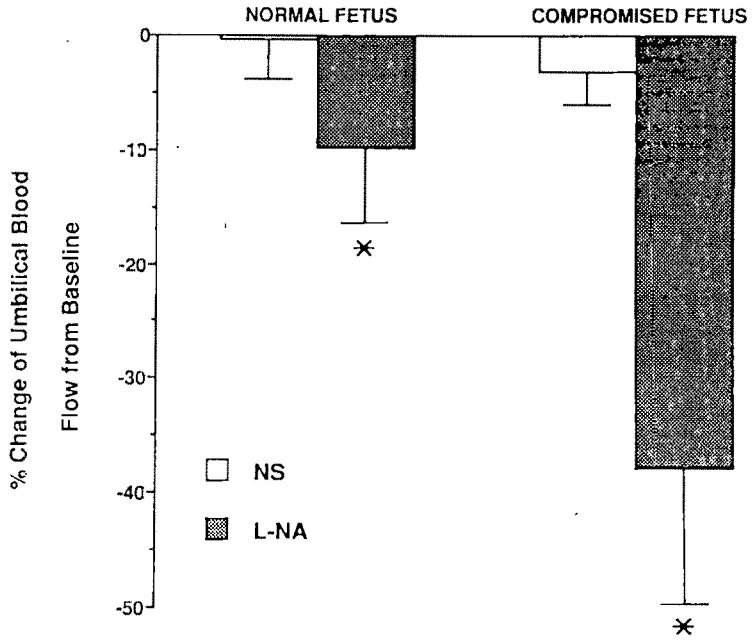

Fig. 3. Percent change in umbilical blood flow from baseline after infusions of normal saline solution *(NS)* and N$^{\omega}$-nitro-L-arginine *(L-NA)*, respectively. *Asterisk*, $p < 0.05$, N$^{\omega}$-nitro-L-arginine versus normal saline solution group.

resting umbilical vascular tone. A recent report by Chaudhuri et al.[9] may explain these differences because they showed that human umbilical arteries in vitro are less sensitive to EDRF than are chorionic plate arteries. It also is possible that the mechanism of stimulation of EDRF production differs between sites or even species. In this in vivo study we found that umbilical vascular resistance increased after a selective 60-minute infusion of N$^{\omega}$-nitro-L-arginine, an L-arginine analog that competitively inhibits the synthesis of EDRF from L-arginine. Although we did not demonstrate N$^{\omega}$-nitro-L-arginine specificity in these particular animals by reversing its effects with L-arginine, we have done this previously in newborn lambs[19] and also in a different group of fetal lambs (unpublished observations). These findings are consistent with those from the in vitro studies of Myatt et al.[7] and Chaudhuri et al.[8, 9] and show that basal release of EDRF might play an important role in maintenance of a low umbilical vascular resistance.

Autoregulation is an important physiologic mechanism for maintenance of constant organ blood flow with variations in arterial blood pressure. However, current evidence indicates that there is little autoregulation in the umbilical circulation.[25] Because the umbilical arteries are not innervated beyond their proximal segment, perfusion pressure is considered a major determinant of blood flow through the relatively passive umbilical circulation.[26] In this study, after infusion of N$^{\omega}$-nitro-L-arginine, both the systemic arterial pressure and calculated umbilical vascular resistance were increased and umbilical blood flow was decreased, in spite of the increase in perfusion pressure. This indicates that EDRF is normally produced in the resting fetal state and acts as an umbilical-placental vasodilator on a continuing basis, thereby regulating basal vascular tone.

We found that umbilical blood flows were markedly decreased by N$^{\omega}$-nitro-L-arginine infusion in compromised fetal lambs and that fetal condition deteriorated, whereas it was well tolerated in normal fetal lambs. This further suggests an important role for EDRF in maintaining umbilical-placental perfusion during periods of fetal stress. The stereospecific analog of L-arginine therefore appears to be a useful pharmacologic tool for further studies of basal or stress-related release of EDRF by the umbilical circulation.

Reliable information about the reactivity of the intact umbilical circulation to vasoactive drugs is scant because several factors may obscure or modify the responses during study. For example, umbilical vasospasm may be sustained during studies of acutely exteriorized animal models or in isolated perfused placental preparations.[27, 28] In addition, some investigators also found that when vasoactive drugs are infused into the inferior vena cava to evaluate the effects on the umbilical circulation, the systemic effects might obscure the true results. Parisi et al.[29] pointed out an unexpected result in their study. They found that administration of prostacyclin to the fetal lamb through the inferior vena cava apparently did not cause umbilical vasodilatation but

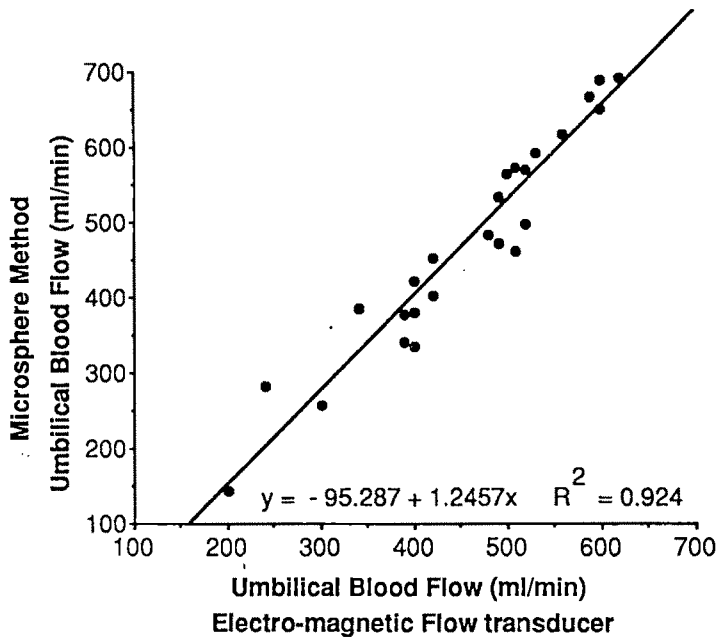

Fig. 4. Comparison of umbilical blood flow measurements derived from injections of microspheres and those recorded simultaneously by electromagnetic flow transducer.

caused vasoconstriction. This resulted from systemic and pulmonary vasodilatation shunting blood away from the placenta to the fetal lung. Therefore we used chronic unanesthetized preparations and infused Nω-nitro-L-arginine directly into the umbilical circulation to attempt to evaluate the true effects on the umbilical-placental circulation without additional stresses imposed and to avoid any possibility that these might modify the results. Although we allowed only a 2- to 4-day postsurgical recovery period, all baseline measurements in our normal group of animals were similar to those previously recorded by us and others in many different studies. We therefore consider that these studies were performed under relatively stress-free conditions.

In clinical situations maintaining an adequate umbilical circulation is essential for fetal growth. In the past, several authors have suggested that the synthesis of prostacyclin or EDRF by umbilical arteries of babies born to mothers after complicated pregnancies could be impaired.[30, 31] In addition, Pinto et al.[31] further considered that the production and release of EDRF by human umbilical vessels was inhibited because cytotoxic materials destroyed endothelial function and showed that the production of EDRF could not be restored by an infusion of superoxide dismutase or L-arginine.[31] Hence EDRF, together with prostacyclin, may play an important role in controlling platelet and leukocyte accumulation in the umbilical vascular wall and in regulating smooth muscle contraction to maintain adequate umbilical blood flow. Impairment of EDRF production could then result in intrauterine growth retardation.

In summary, the hemodynamic effects of Nω-nitro-L-arginine, a stereospecific L-arginine analog, on the umbilical-placental circulation in intact fetal lambs suggest that EDRF plays an important role in maintaining the normal low resistance in this circulation. We think impairment of EDRF production may contribute to umbilical vascular disorders, especially in babies born to preeclamptic mothers. Further studies may elucidate an important pathophysiologic mechanism for fetuses with intrauterine growth retardation or asphyxia without apparent reasons.

GnRH Analogs: Optimal Management Strategies

The following papers are from presentations given at the symposium, "GnRH Analogs: Optimal Management Strategies," held in New Orleans, Louisiana, on May 6 to 7, 1991.

This symposium was supported by a grant from Syntex Laboratories, Palo Alto, California.

Nafarelin in the management of endometriosis: Quality of life assessment

Kenneth A. Burry, MD

Portland, Oregon

Quality of life is important when comparing the relative advantages of nafarelin versus danazol for the treatment of endometriosis. Recent studies have investigated the potential differences between the safety profiles of nafarelin and danazol and the impact of these profiles on the patient's quality of life. Results show that although these drugs have similar efficacy, they are associated with very different safety profiles. Most notable are the androgenic effects such as weight gain associated with danazol. With nafarelin, hypoestrogenic side effects, such as hot flashes, are more common. More important, these differences in safety profiles may prove to be relevant to patient satisfaction and compliance with therapy. (AM J OBSTET GYNECOL 1992;166:735-9.)

Key words: Quality of life, androgenic, hypoestrogenic

The efficacy of nafarelin acetate in reducing the size of endometriotic implants has been demonstrated repeatedly in controlled trials.[1-4] Nafarelin dosages of 400 μg daily have compared favorably with 800 mg of danazol daily when laparoscopic scores were compared.[1, 2] These studies, conducted in the United States and Europe, have also shown that nasally administered nafarelin reduced both estradiol and estrone levels to the range associated with medical castration. In contrast, orally administered danazol, although achieving reductions in circulating levels of these hormones, did not achieve medical castration. These findings provide evidence to suggest that although both medical therapies are effective against endometriosis, they are not interchangeable with respect to their safety profiles. Indeed, data suggest that important differences exist between nafarelin and danazol that are not directly related to the objective measurement of improvement in endometriotic implants. Whether the goal is treatment of infertility or relief of pain and other symptoms, a careful examination is needed of the potential risks posed by treatment of endometriosis. Clinical experience with danazol suggests that its efficacy is often achieved at a cost of an increased incidence of androgenic side effects, such as weight gain, acne, and hirsutism.[4-6] Thus an alternative therapy that is associated with either fewer or more tolerable side effects is of clinical interest.

Estimates of the number of women with endometriosis are confounded by the considerable proportion who remain without symptoms. A definitive diagnosis still requires direct visualization with laparoscopy or laparotomy. Nevertheless, it has been suggested that as many as 7% of women of reproductive age (15 to 45 years of age) are affected by endometriosis[7] and that the rate of clinical recurrence after discontinuation of therapy is high.[8] Common symptoms in women who consult a physician for possible endometriosis are dysmenorrhea, dyspareunia, dyschezia, and abnormal menstrual bleeding; however, the symptom responsible for most patient complaints is chronic pelvic pain. The persistence of pelvic pain can have a negative impact on physical and sexual function as well as a sense of well-being and other psychological aspects. The result may be a measurable decrease in the patient's quality of life.

The potential impact on quality of life on the patient has prompted comparisons between nafarelin and danazol. The intent of these investigations is to evaluate the efficacy of these agents in the context of quality of

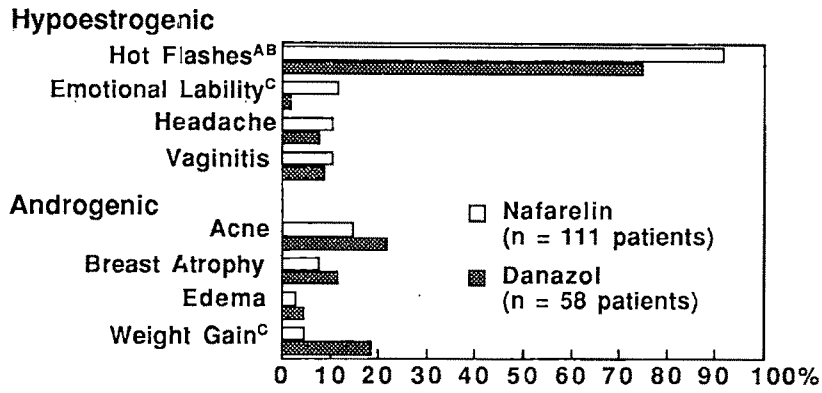

Fig. 1. Summary of most frequent adverse effects (probably related to therapy) in patients treated with nafarelin or danazol.[1] *A*, Women with hot flashes before treatment were excluded (five nafarelin; one danazol). *B*, $p < 0.01$ for between-treatment difference. *C*, $p < 0.05$ for between-treatment difference.

life variables using both objective and subjective measures of patient response. Danazol, administered orally in therapeutic doses of 800 mg daily, is a synthetic derivative of 17α-ethinyl testosterone that directly inhibits enzymatic synthesis of ovarian steroids and inhibits pituitary gonadotropin secretion. It is also highly androgenic partly because of perhaps increased androgen bioavailability that results from danazol binding to sex hormone–binding globulin.[9] This results in a substantial increase in free testosterone, which probably contributes to the androgenic side effects, such as hirsutism, lowering of voice, and especially weight gain, that are associated with danazol.

Nafarelin, administered as a nasal spray, is an analog or agonist of gonadotropin-releasing hormone (GnRH). When administered long term in dosages ranging from 400 to 800 μg daily, it paradoxically suppresses the release of luteinizing hormone and follicle-stimulating hormone, which in turn suppress gonadal production of estradiol and testosterone.[9] Both drugs deprive endometriotic implants of the gonadal steroids they need to remain viable.

Safety profiles

Nafarelin versus danazol. In the recent U.S. study,[1] 169 patients with laparoscopically confirmed endometriosis were enrolled in a multicenter, double-blind study. The randomization procedure assigned two of every three patients to receive nafarelin, 400 μg daily ($n = 111$), and one of three patients to danazol, 600 mg daily ($n = 58$). All patients were evaluated before treatment, 2 weeks after beginning treatment, monthly throughout the 6-month study period, and 1 month after therapy was stopped. Symptoms of endometriosis, such as pelvic pain, dyspareunia, and dysmenorrhea, were evaluated; pelvic examinations were performed; and all patients were asked to complete questionnaires designed to evaluate changes in quality of life indicators.

Of the patients randomized, six receiving nafarelin and three receiving danazol discontinued treatment because of adverse effects. An additional patient receiving danazol withdrew because of elevated liver enzyme levels. Twelve other patients were withdrawn for administrative reasons. A comparison of the 98 nafarelin-treated and 49 danazol-treated patients who completed the treatment phase of the study revealed that the two populations were well matched demographically. There was no statistically significant difference between the groups with regard to age, severity of clinical symptoms at admission, complaints of infertility, or history of pelvic inflammatory disease. The percentage of patients who desired pregnancy, pain relief, or both was also similar in the two groups.

The two therapies were similar in the magnitude of change in laparoscopic scores. Specifically, 77% of the nafarelin group and 83% of the danazol group had lower laparoscopic scores at the end of treatment compared with baseline scores. Similarly, equal efficacy was seen in the improvement in symptom scores. Patients reporting mild or no symptoms of endometriosis at the end of therapy comprised 96% of the nafarelin group and 92% of the danazol group. Among those who were reevaluated 6 months after the end of treatment, 79% of the nafarelin group and 75% of the danazol group reported mild or no symptoms.

Although the vast majority of patients found the side effects associated with the assigned therapy to be acceptable, approximately 5% of patients initially randomized to each study group discontinued therapy because of adverse events. Although the percentage of patients discontinuing therapy in the two groups was similar, the incidence of specific adverse effects differed substantially between the two groups.

The adverse effects associated with treatment could be divided into two categories: hypoestrogenic and androgenic effects (Fig. 1). As expected hypoestrogenic effects were more pronounced in nafarelin-treated pa-

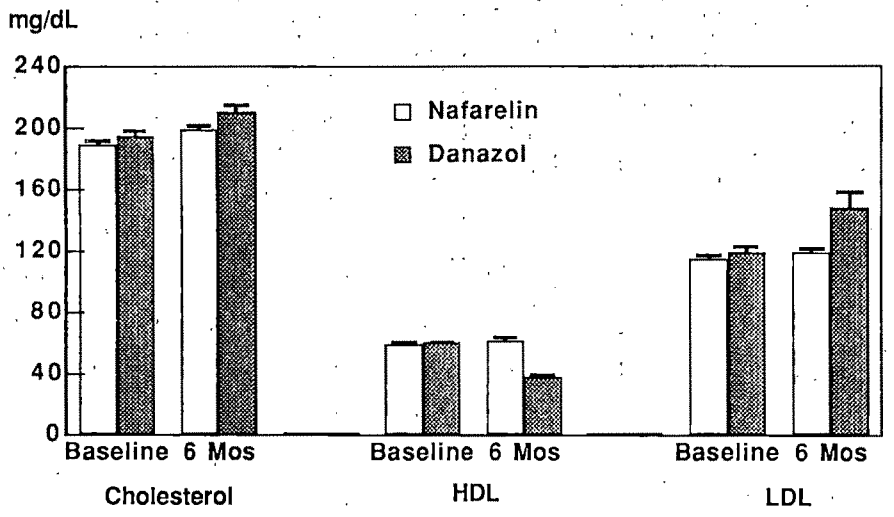

Fig. 2. Mean (±SE) lipid concentrations at baseline and after 6 months treatment with nafarelin or danazol for endometriosis.[1] *HDL,* High-density lipoprotein; *LDL,* low-density lipoprotein.

tients than in those receiving danazol. The incidence of hot flashes was 92% among those receiving nafarelin compared with 75% in patients receiving danazol ($p < 0.01$ for between-treatment differences). Emotional lability also was more common in the nafarelin group (12%) than among danazol-treated patients (2%; $p < 0.01$ for between-treatment differences). In addition, an increased incidence of headache and vaginal dryness (and vaginitis) was reported in the nafarelin group compared with danazol-treated patients. However, none of the nafarelin-treated patients discontinued therapy because of these symptoms.

Androgenic side effects were more marked among patients treated with danazol. The adverse effect responsible for most complaints was weight gain. In the U.S. study, 19% of patients in the danazol group complained of weight gain compared with only 5% in the nafarelin group ($p < 0.01$ for between-treatment differences). By the third month of treatment, there was a significant difference in weight between patients treated with danazol versus those given nafarelin. Moreover, no woman taking nafarelin showed an appreciable change in mean body weight throughout the 6-month study. Other androgenic adverse effects such as acne, breast atrophy, and edema tended to occur more frequently in danazol-treated patients. Myalgia, which was reported by 12% of danazol-treated patients, occurred in only 2% of those who received nafarelin. Also, seborrhea, hirsutism, and increased libido occurred more frequently in patients who received danazol.

The effects of nafarelin and danazol on lipid profiles were also evaluated. Results showed that danazol was associated with a significant ($p < 0.01$) decrease in high-density lipoproteins and an increase in low-density lipoproteins. In contrast, nafarelin significantly ($p < 0.01$) raised high-density lipoprotein levels, whereas low-density lipoprotein levels were unchanged (Fig. 2).[1] Deterioration of lipid profiles after danazol therapy may represent increased risk to the patient's cardiovascular profile.

Additionally, one patient in the danazol group and no patient in the nafarelin group discontinued therapy as a result of an abnormal liver function test. Patients treated with danazol have shown increases in alanine aminotransferase and creatine phosphokinase levels into the abnormal range; these effects are not observed with nafarelin.[10]

Quality of life evaluation. The quality of life measurements in the U.S. study were obtained by a questionnaire composed of 22 simple questions that comprised the Psychological General Well-Being Index plus a modification of Part II of the Nottingham Health Profile, which requires only a patient's visual qualification of psychological state rather than a numerical quantification. The psychological and general well-being score reveals types of psychological conditions such as anxiety, depressed mood, positive well-being, self control, general health, and vitality. The health profile looks into aspects of the patient's life such as work; the quality of work produced, self-image, ability to handle domestic concerns, social life, home life, sex life, outside activities, and quality of time spent away with the family.

The results of these questionnaires failed to reveal statistically significant differences between the entire treatment group. However, when those patients seeking relief of symptoms of endometriosis were evaluated separately from those seeking pregnancy only, a difference in scores was observed. For example, patients in both treatment groups who were seeking pregnancy began with and maintained a positive score for work-related quality of life. However, patients seeking pain relief started with a depressed work score that im-

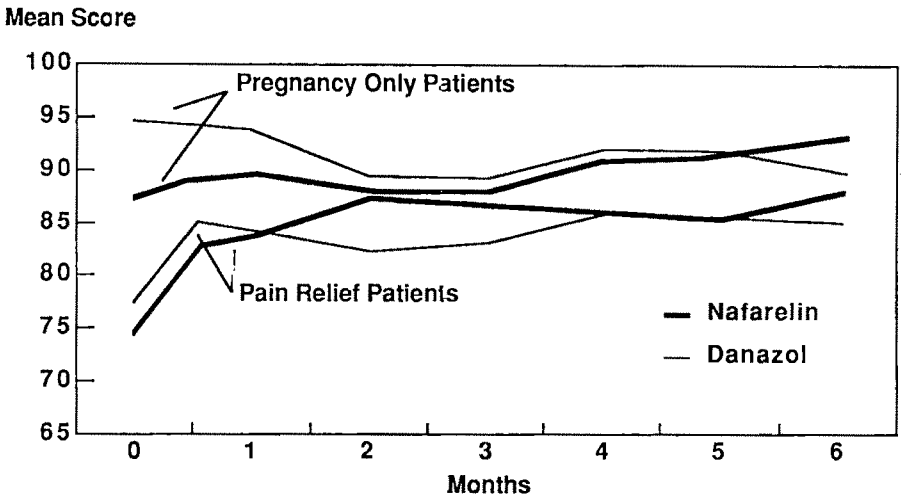

Fig. 3. Effect of treatment with nafarelin or danazol on quality of work scores.[1] Scores were stratified according to those seeking pain relief only or those seeking pregnancy.

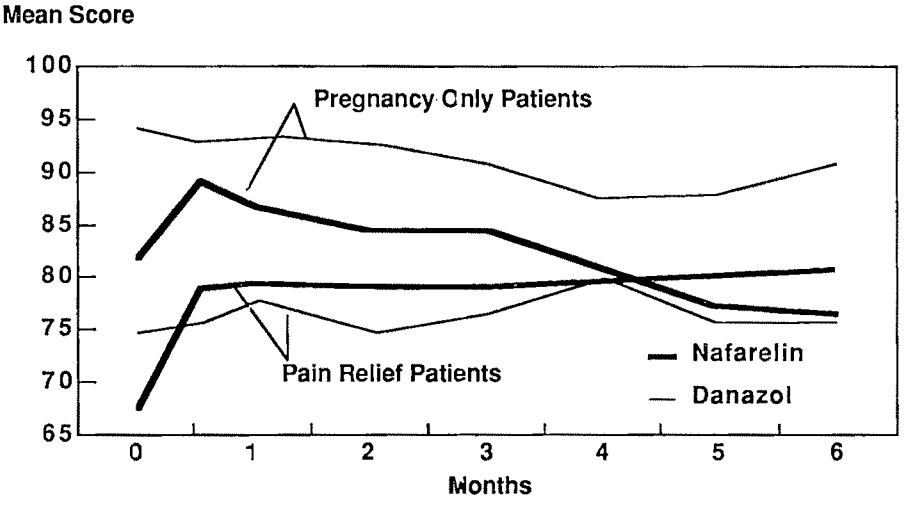

Fig. 4. Effect of treatment with nafarelin or danazol on the quality of sexual function.[1] Scores were stratified according to those seeking pain relief only or those seeking pregnancy.

proved during nafarelin but not during danazol treatment (Fig. 3). Although there were no between-group differences, overall, the nafarelin group showed significant ($p < 0.05$; paired t test) improvement from baseline in work productivity at all assessments, whereas there was no significant change in this measure in the danazol group.

The Nottingham Health Profile revealed another difference between the two treatment groups with respect to the quality of sexual function. Danazol-treated patients showed no significant improvement in quality of sexual function during treatment. Nafarelin-treated patients seeking pain relief had a lower mean score at baseline but did achieve and maintain a significant ($p < 0.01$; paired t test) improvement in quality of sexual function after 1 month of therapy (Fig. 4). The improved sexual function in this subgroup likely was the result of reduced pain in general and an improvement in dyspareunia. There was actually a decrease in the mean score over time among nafarelin-treated patients seeking pregnancy, however, this change was not statistically significant. Failure to show improvement in sexual function in the infertility subgroup, particularly in nafarelin-treated patients seeking pregnancy, was chiefly because of the complaint of vaginal dryness, an adverse effect associated with both nafarelin and danazol.

Comment

In the most recent U.S. study[1] and in past studies,[4-6, 11] nafarelin and danazol demonstrated similar efficacy for the treatment of endometriosis based on lap-

aroscopic scores. Thus the most important differences between these two agents may be their safety profiles and effect on the patient's perception of quality of life.

As has been shown in the past,[4-6, 12] most of the side effects attributed to danazol in this investigation were associated with its androgenic and anabolic properties. Although the 600 mg/day dose of danazol administered in this study is lower than the 800 mg/day typically administered for the management of endometriosis, the incidences of myalgia, weight gain, and acne still rose significantly above baseline levels and above incidences of these adverse effects in patients who received nafarelin. In contrast, the adverse effects associated with nafarelin appear to be associated primarily with hypoestrogenism.

A sensitive, qualitative instrument for measurement of quality of life in patients with endometriosis was difficult to find. Most instruments have been developed for an older population with chronic diseases. The quality of life profiles used in the U.S. study are generally not sensitive enough to differentiate between danazol and nafarelin. Scores of the Psychological General Well-Being Index improved significantly from baseline in both treatment groups. However, the Nottingham Health Profile scale did show that nafarelin was associated with a significant improvement in work-related indexes of quality of life that were not exhibited in the danazol group. Notably, when patients were grouped according to the goal of therapy, patients seeking pain relief showed an improvement in baseline quality of life measures, and the improvement seen with nafarelin on these measures was greater than with danazol.

More important, there is considerable evidence that nafarelin is comparable with danazol for the treatment of endometriosis. Because nafarelin exhibits a safety profile that is somewhat different from that of danazol, it represents an alternative to patients who cannot or are unwilling to tolerate danazol. Clinicians are more able to evaluate the relative risks of these two alternative therapies and to select an agent better suited to the goals and concerns of the individual patient.

I thank the following clinicians who participated in the study: Canada, J. Z. Scott, J. E. H. Spence, and A. A. Yuzoz; United States, V. C. Buttram, S. L. Corson, R. Davey, M. Farber, C. B. Hammond, A. J. Kresch, R. D. Miller, K. S. Moghissi, R. Rheindollar, and L. Wan. I also thank J. F. Gross for her assistance.

Hormone treatment of endometriosis: The estrogen threshold hypothesis

Robert L. Barbieri, MD
Stony Brook, New York

In women with recurrent pelvic pain caused by endometriosis, hormonal therapy with a gonadotropin-releasing hormone agonist is an effective alternative to surgical therapy. The basis for medical treatment of endometriosis is that endometriosis lesions are dependent on estradiol for continued growth. Further, end organ tissue varies in its sensitivity to estradiol. This forms the basis of the estrogen threshold hypothesis, that is, that a concentration of estradiol that will partially prevent bone loss may not stimulate endometrial growth. Thus there is a hierarchy of organ response to estradiol such that calcium metabolism is most sensitive followed by gonadotropin secretion, vaginal epithelial growth, lipid metabolism, and liver protein production. Similarly, breast cancer is most sensitive and endometriosis is least sensitive to estrogen. These differences may allow the design of regimens with a gonadotropin-releasing hormone agonist that maintain a therapeutic response and ameliorate potential adverse effects. (AM J OBSTET GYNECOL 1992;166:740-5.)

Key words: Endometriosis, estradiol, gonadotropin-releasing hormone agonists, progestins

Endometriosis is the presence of tissue resembling endometrial glands and stroma outside the uterine cavity. Women with endometriosis typically present for medical care with one of three problems: an adnexal mass (endometrioma), infertility, or pelvic pain. For women with an endometrioma, surgical removal of the mass is both diagnostic and therapeutic. For women with stage III or stage IV endometriosis and infertility, surgical resection of endometriotic lesions and adhesions probably improves fecundity.[1,2] For women with pelvic pain, diagnostic laparoscopy may reveal the presence of endometriosis. At the time of initial surgical diagnosis, most clinicians will attempt to ablate the endometriosis with laser or electrosurgical techniques. Some clinicians would also advocate ablation, transection, or resection of the uterosacral ligaments at the time of initial surgical diagnosis. Many women with endometriosis and pelvic pain experience relief of pelvic pain for 3 to 12 months after such surgical procedures. However, in my experience, after such surgical procedures, most women will have a recurrence of pain within 12 months. For these women with recurrent pelvic pain caused by endometriosis, hormone therapy is an appropriate therapeutic choice and is usually very effective. The basis for hormone treatment of endometriosis is that endometriotic lesions are dependent on estradiol for their continued growth.

Endometriosis is estrogen dependent

Clinical observations that suggest that endometriosis is sensitive to estrogen include the following: (1) Endometriosis is rare before puberty or after menopause; (2) surgical removal of both ovaries typically results in regression of endometriotic lesions; (3) production of a hypoestrogenic state with a gonadotropin-releasing hormone (GnRH) agonist such as nafarelin or leuprolide results in regression of endometriosis; and (4) endometriosis can develop in the prostatic utricle of men treated with diethylstilbestrol for prostate cancer.[3] Immunocytochemical studies indicate that virtually all endometriotic lesions contain estrogen receptors.[4] In experimental rat and human models of endometriosis, hypoestrogenism produces atrophy in endometriotic lesions, and estrogen administration causes the endometriotic lesions to grow.[5,6] In humans, the precise concentration of estradiol that will cause endometriotic lesions to atrophy or grow remains to be defined. However, estradiol concentrations in the range of 10 to 20 pg/ml typically result in the atrophy of endometriotic lesions.[7-10] Estradiol concentrations greater than 60 pg/ml are often associated with the growth of endometriotic lesions. Although estradiol concentrations in the range of 10 to 20 pg/ml result in the regression of endometriotic lesions, they also may be associated with loss of trabecular bone mineral, vasomotor symptoms, and atrophy of secondary sexual characteristics.[7-10] An important question is whether a circulating estradiol concentration in the range of 30 to 45 pg/ml might be associated with no growth of endometriotic lesions and minimal changes in bone mineral density. Preliminary evidence to support this concept is reviewed below.

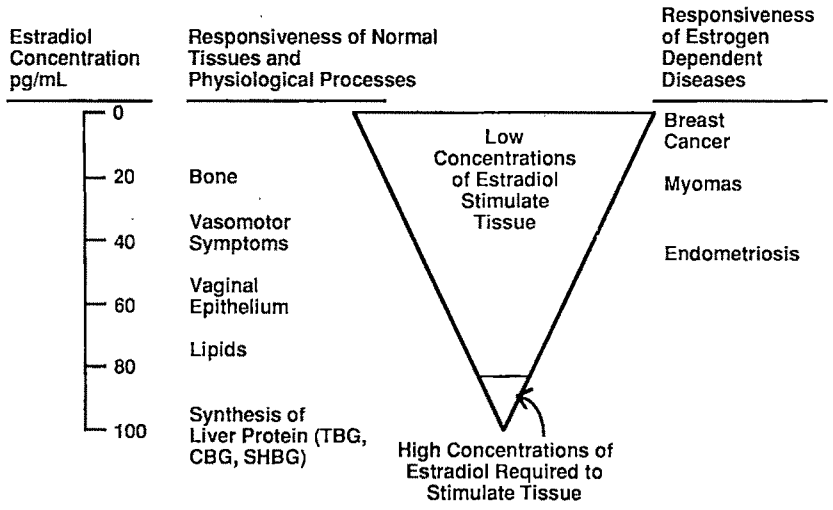

Fig. 1. Hierarchy of tissue and disease response to various concentrations. Calcium metabolism and bone may be more sensitive to estradiol than vaginal epithelium and lipid metabolism. *TGB*, Thyroid-binding globulin; *CBG*, cortisol-binding globulin; *SHBG*, sex hormone–binding globulin.

Tissues vary in their sensitivity to estradiol

The essence of the estrogen threshold hypothesis is that tissues vary in their sensitivity to estradiol and that a concentration of estradiol (30 to 45 pg/ml) that will partially prevent bone loss may not stimulate endometriotic lesions to grow. Evidence to support the concept that tissues vary in their sensitivity to estradiol has been provided by Chetowski et al.[11] In a brilliantly designed and executed study, Chetowski et al. randomized menopausal, hypoestrogenic women to receive one of four different doses of transdermal estradiol: 25, 50, 100, or 200 μg/day or two doses of oral conjugated estrogens, 0.625 or 1.25 mg/day.

Before estradiol replacement therapy was initiated, women had a circulating estradiol concentration of less than 10 pg/ml, elevated urinary calcium excretion, elevated serum gonadotropin concentrations, decreased vaginal superficial epithelial cells, and elevated low-density lipoprotein cholesterol. The transdermal estradiol replacement therapy produced an increase in circulating estradiol proportional to the dose administered. For example, at doses of 25, 50, 100, and 200 μg/day, the circulating estradiol concentrations were approximately 28, 25, 65, and 110 pg/ml, respectively. At the lowest estradiol replacement dose, 25 μg/day, a significant decrease in urinary calcium excretion and follicle-stimulating hormone concentration was noted. However, an estradiol replacement dose of 25 μg/day produced no significant change in luteinizing hormone concentration, vaginal superficial epithelial cells, or circulating lipids. This suggests that calcium turnover may be exquisitively sensitive to estradiol. This contrasts to the relative lack of sensitivity of vaginal epithelium and circulating lipids to small doses of estradiol. At an estradiol replacement dose of 100 μg/day, urinary calcium excretion was suppressed, follicle-stimulating hormone and luteinizing hormone concentrations were decreased, and vaginal superficial cells increased. This indicates that to increase the percentage of vaginal superficial cells, more estradiol is needed than required to suppress urinary calcium excretion.

These observations suggest a hierarchy of responsiveness of various organs to estradiol. Fig. 1 depicts this hierarchy. From the studies of Chetowski et al.,[1] it appears that the hierarchy of most sensitive to least sensitive estrogen-responsive processes is: (1) calcium turnover, (2) gonadotropin secretion, (3) vaginal epithelial growth, (4) lipid production, and (5) liver protein production, such as sex hormone–binding globulin production. In a like manner, estradiol-dependent disease processes also appear to have a hierarchy of responsiveness to estradiol. Breast cancer can be very sensitive to the growth-promoting effects of estradiol concentrations as low as 10 to 20 pg/ml.[12] To reduce myoma volume in premenopausal women by 50%, estradiol concentrations in the range of 15 to 25 pg/ml must be achieved.[13, 14] Estradiol concentrations in the range of 30 pg/ml reliably produce regression in endometriotic lesions.[15] The hierarchy of most sensitive to least sensitive estrogen-responsive disease processes appears to be: (1) breast cancer, (2) myomas, and (3) endometriosis (Fig. 1).

The estrogen threshold hypothesis: Surgical oophorectomy and estrogen add-back

At very low concentrations of estradiol (in the range of 10 to 20 pg/ml), most endometriotic lesions regress, but bone mineral loss can be substantial. At high estradiol concentrations (in the range of 100 to 300 pg/ml), endometriotic lesions can grow, but bone min-

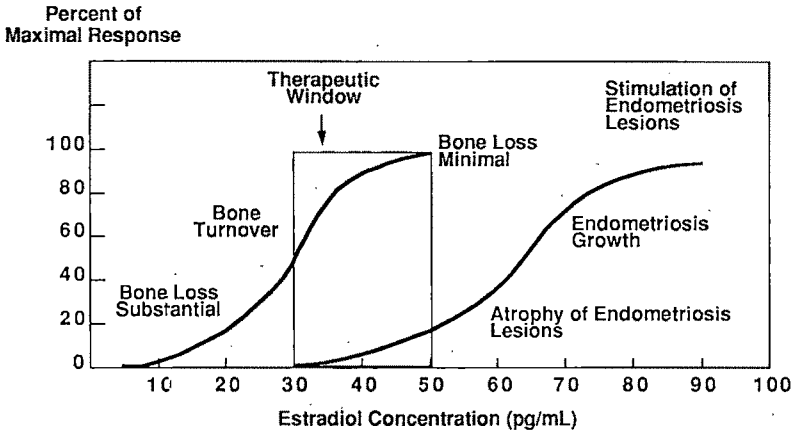

Fig. 2. Estradiol therapeutic window. The concentration of estradiol required to cause growth of endometriosis lesions may be greater than the concentration required to stabilize bone mineral density.

eral density does not decrease. Evidence to support the concept that there may be an "estradiol therapeutic window" comes from studies in which surgical oophorectomy plus estrogen add-back was used to successfully treat women with endometriosis.[16-18] Before reviewing these studies, it should be noted that no randomized prospective studies to assess the risks and benefits of estrogen replacement therapy in women with endometriosis who have undergone bilateral oophorectomy and hysterectomy for the treatment of endometriosis have been reported. All the studies to date are retrospective studies with no control group and are subject to a variety of possible biases. However, the results of all three retrospective studies are similar: estrogen replacement therapy after total hysterectomy and bilateral oophorectomy (TAH-BSO) was associated with a low rate (<10%) of recurrence of endometriosis. For example, Ranney[18] reported on 144 women with endometriosis who were treated with definitive surgery (TAH-BSO). Of these women, 48 patients were not given estrogen replacement therapy because 13 had severe involvement of the bowel or ureters by endometriosis, 15 had endometrial, ovarian, or breast cancer, and 20 had no menopausal symptoms. The remaining 96 women received ethinyl estradiol in oral doses between 0.02 and 0.05 mg daily. For 32 women, the hormone therapy was started more than 3 months after the surgery. In 3 of these 96 patients, the symptoms of endometriosis recurred, which required the discontinuation of the estrogen therapy. Gray[16] observed similar results, with 8 of 56 women developing recurrent endometriosis during treatment with conjugated estrogens (0.3 or 0.6 mg) after TAH-BSO. The observation that doses of estrogen known to protect bone mineral density can be safely prescribed to most women with endometriosis who undergo TAH-BSO strongly suggests the existence of an estrogen therapeutic window (Fig. 2).

If surgical oophorectomy plus estrogen add-back can be successful in the treatment of endometriosis, then medical oophorectomy with the GnRH analogs plus estrogen add-back also might be successful. To date no large randomized prospective trials to test this hypothesis have been published. Such studies are currently being conducted. Until these studies are completed, the precise risks and benefits of a treatment strategy combining long-term GnRH analog therapy with estrogen-progestin add-back will be unclear. However, from my clinical experience in the treatment of women with endometriosis and pelvic pain, the regimens combining long-term GnRH analog therapy with low-dose estrogen replacement appear to be effective in controlling pelvic pain and minimizing the loss of bone mineral density.

The estradiol therapeutic window

The basic tenant of the estradiol threshold hypothesis is that tissues vary in their sensitivity to estradiol (Fig. 1). Bone and calcium metabolism may be very sensitive to estradiol, whereas many endometriotic lesions are somewhat less sensitive to estradiol. This difference in estradiol sensitivity means that an estradiol therapeutic window may exist (Fig. 2). At estradiol concentrations of less than 20 pg/ml, endometriotic lesions will tend to atrophy, but loss of bone mineral density will be substantial. At estradiol concentrations of greater than 100 pg/ml, endometriotic lesions will flourish, but loss of bone mineral will not occur. At estradiol concentrations of 30 to 45 pg/ml, many endometriotic lesions may not be stimulated to grow, and

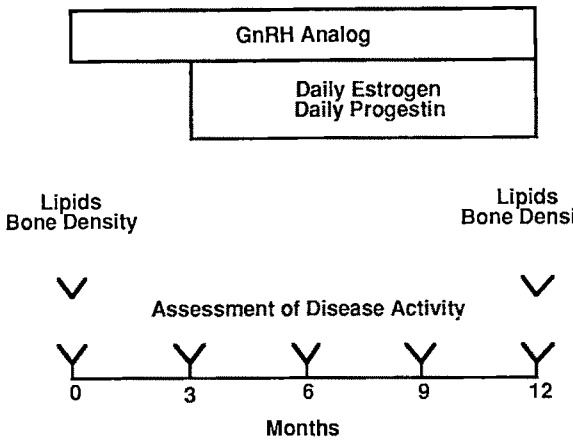

Fig. 3. Regimen I. GnRH analog is used as a single agent for 3 months to produce regression of endometriotic lesions. Combined GnRH analog plus daily estrogen-progestin therapy is then initiated to try to prevent the adverse effects associated with a prolonged hypoestrogenic state.

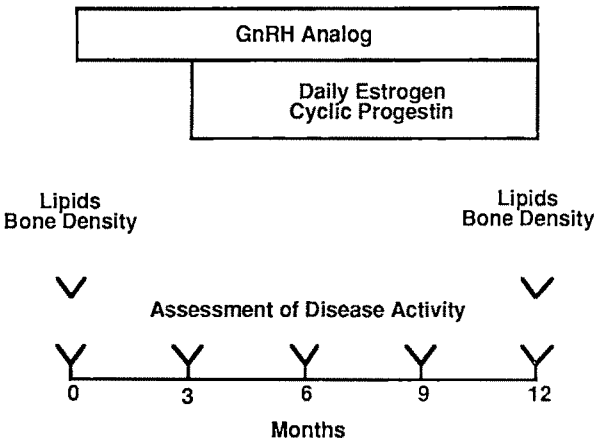

Fig. 4. Regimen II. GnRH analog is used as a single agent for 3 months to produce regression of endometriotic lesions. Combined GnRH analog plus daily estrogen and cyclic progestin therapy is then initiated to try to prevent the adverse effects associated with a prolonged hypoestrogenic state.

bone loss may be minimal. Whether an estradiol therapeutic window exists in every woman is unclear. An occasional endometriotic lesion may be extremely sensitive to the stimulatory effects of estradiol. In addition, the "width" of the window may vary from woman to woman. In some women, the window may be extremely narrow, and it may be difficult to target the circulating estradiol concentration to stay within the estradiol therapeutic window.

The estrogen threshold hypothesis: Practical applications in the treatment of endometriosis

The design of clinical trials to evaluate the efficacy of medical treatment of endometriosis is complicated by the need for repetitive laparoscopies to objectively evaluate the extent of disease. Many women are unwilling to enter study protocols in which two or more laparoscopies will be required. Consequently, many investigators interested in the biology and treatment of estrogen-dependent gynecologic diseases have turned to uterine leiomyomas as their experimental model of choice. The prevalence of uterine leiomyomas is very high; thus many women are eligible for study protocols. In addition, the objective response of uterine myomas to medical treatment can be monitored with noninvasive techniques such as sonography, magnetic resonance imaging, and physical examination. Many of the management principles generated in studies of the medical treatment of myomas may be applicable to the treatment of endometriosis. A basic management principle in the use of long-term combined GnRH analog plus estrogen-progestin add-back therapy is to treat with the GnRH analog alone for 3 months and then

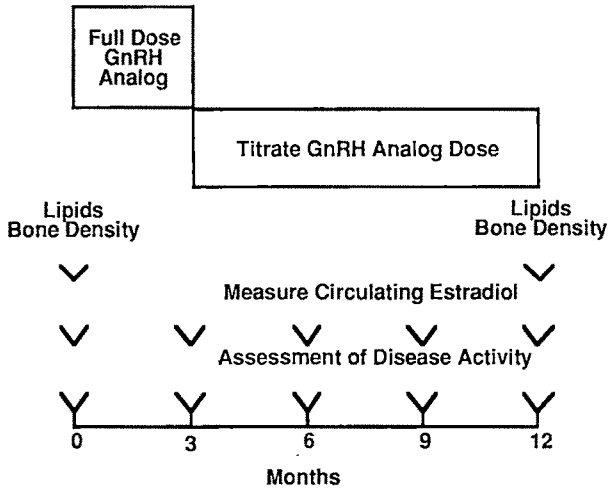

Fig. 5. Regimen III. GnRH analog is used as a single agent at full dose for 3 months to produce regression of endometriotic lesions. The dose of GnRH analog is then titrated in an attempt to produce a circulating estradiol in the range of 30 to 45 pg/ml.

"add-back" estrogen plus progestin.[13, 19, 20] This strategy allows the GnRH analog to produce near-maximal regression of disease before steroid add-back. It is possible that the hypoestrogenic state forces the estrogen-dependent disease into a state of "hibernation" in which it is less responsive to the possible stimulating effects of the estrogen-progestin add-back. This basic principle is incorporated into all the treatment regimens described below.

Four regimens that I have used in the long-term hor-

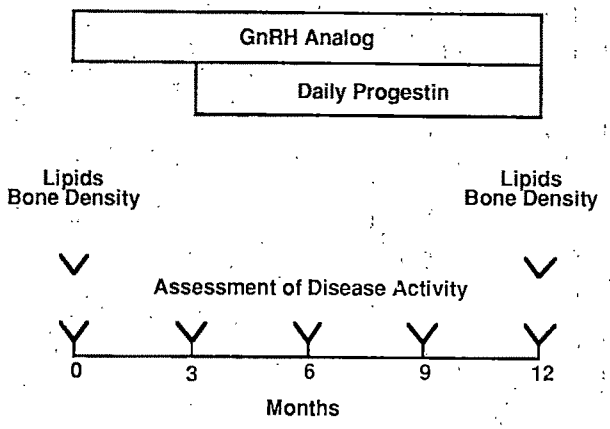

Fig. 6. Regimen IV. GnRH analog is used as a single agent for 3 months to produce regression of endometriotic lesions. Combined GnRH analog plus daily progestin therapy is then initiated to try to prevent the adverse effects of a hypoestrogenic state.

monal treatment of endometriosis are presented in Figs. 3 to 6. The efficacy of these regimens has not been documented in large prospective, randomized trials. Surgical documentation of endometriosis is necessary for patients to be entered into these treatment regimens. For all long-term regimens (>6 months of GnRH analog therapy), measurement of serum lipids and bone mineral density may be useful to gauge potential adverse effects of these protocols. The clinician might also want to ensure that the patient is receiving adequate dietary calcium.

Regimen I involves the use of a GnRH analog alone for 3 months followed by the combined use of GnRH analog plus continuous daily estrogen plus progestin. In initiating the estrogen add-back, low doses of estrogen can be used (0.3 mg of conjugated estrogen daily; 50 μg/day of transdermal estradiol), and the dose of estrogen can be increased (0.625 mg of conjugated estrogen) if symptoms and physical findings suggest that the endometriosis is in good control. Oral medroxyprogesterone, 2.5 mg daily, or norethindrone, 0.35 mg daily, can be used as the progestin.

In regimen II, a GnRH analog alone is used for 3 months followed by the combined use of GnRH analog plus continuous daily estrogen and cyclic progestin. As in regimen I, the clinician may want to use low doses of estrogen in initiating the estrogen add-back (0.3 mg of conjugated estrogen daily) and the estrogen dose can be increased (0.625 mg of conjugated estrogen daily) if symptoms and physical findings suggest that the endometriosis is in good control. In women receiving the combined GnRH analog plus daily estrogen replacement therapy, the frequency of progestin cycles needed to prevent endometrial hyperplasia remains to be determined. It is conceivable that endometrial hyperplasia could be prevented by the use of a progestin cycle every other month rather than every month. A disadvantage to regimen II is that cyclic menses, at best with minimal bleeding, may occur. An advantage of regimen II is that minimal doses of progestin are used, which reduces the adverse effects of a progestin on circulating lipids.

In regimen III, a novel approach to "estrogen add-back" is used: adjust the dose of GnRH analog to allow the ovary to produce enough estradiol to achieve a circulating estradiol concentration in the range of 30 to 45 pg/ml. In regimen III, full-dose GnRH analog treatment (e.g., nafarelin nasal solution, 200 μg twice daily) is used for 3 months. The dose of the GnRH analog is then adjusted to produce the desired circulating estradiol concentration. Previous studies suggest that a dose-response relationship exists between nafarelin and circulating estradiol.[15, 21] In using such a regimen, care must be taken to avoid missed GnRH agonist doses. In regimen III the possibility exists that the pituitary-ovarian axis could escape from GnRH analog suppression, and a dominant follicle and ovulation could occur. Patients treated with GnRH analogs should use non-hormonal contraceptives to avoid the rare possibility of a unintended pregnancy.

Regimen IV involves the use of a GnRH analog alone for 3 months followed by the combined use of a GnRH analog plus a daily progestin. Judd et al. have evaluated the use of regimens of combined GnRH analogs plus daily progestin in the treatment of endometriosis.[22, 23] The progestin appears to suppress vasomotor symptoms caused by the GnRH analog. However, progestins are probably not as effective as estrogen in protecting bone mineral density. In addition, high-dose progestins may suppress circulating concentrations of high-density lipoprotein cholesterol, which results in an atherogenic lipid profile. If an estradiol therapeutic window exists, it is probably better to use estrogen add-back than progestin only add-back in combined GnRH analog plus steroid add-back regimens.

Conclusions

Estradiol is an important growth factor for endometriotic lesions.

Hypoestrogenic states clearly result in the atrophy of endometriosis lesions.[7-10]

A major question that is still unresolved is: What *precise* concentration of estradiol is required to produce atrophy of endometriotic lesions? Data that definitively answer this question will allow us to develop truly scientific regimens for the treatment of endometriosis.

Treatment of uterine fibroids: Current findings with gonadotropin-releasing hormone agonists

G. David Adamson, MD
Palo Alto, California

The gonadotropin-releasing hormone agonists have potential benefit as presurgical adjuncts in the management of uterine leiomyomas or fibroids. Uterine fibroids contain estrogen receptors and are responsive to therapeutic hormonal manipulation; gonadotropin-releasing hormone agonists are effective by inducing a state of hypoestrogenism. Clinical trials with gonadotropin-releasing hormone agonists consistently have demonstrated efficacy for decreasing both myoma size and uterine volume. The advantages of the preoperative use of gonadotropin-releasing hormone agonists include a reduction in uterine and myoma size and vascularity and potentially improved operative technique and uterine cavity integrity. Ongoing clinical trials will be needed to confirm the role of gonadotropin-releasing hormone agonists in the treatment of uterine fibroids. (AM J OBSTET GYNECOL 1992;166:746-51.)

Key words: Gonadotropin-releasing hormone analog, leiomyoma, uterine fibroids, leuprolide, nafarelin

Uterine fibroids is a common medical problem among women, and surgery is often recommended for management. Recently, gonadotropin-releasing hormone (GnRH) agonists have been investigated for use in uterine fibroid disease, but many questions remain about their role in overall management. To help clarify the role of GnRH agonists in myomatous uteri, this article will review the effect of GnRH agonists on uterine myomas and the uterus. The clinical implications of these actions and the potential disadvantages of GnRH agonists will also be discussed. Finally, a brief summary of the current role of GnRH agonists in the management of uterine myomas will be offered.

Uterine fibroids

Leiomyomas or uterine fibroids are neoplasms of the smooth muscle found in about 20% of women over the age of 30 years.[1] Although uterine leiomyomas are the most common solid tumor of the female genital tract, they are benign. Thus therapeutic intervention is not required for all women with uterine fibroids. Indications for the treatment of uterine myomas include menorrhagia with iron deficiency anemia, uterine pressure or pain, rapidly increasing fibroid size, recurrent abortion with endometrial cavity distortion, and infertility with endometrial cavity distortion. Unexplained or refractory infertility may also be an indication for myomectomy.[2]

Until recently, there has been no generally accepted medical therapy for the management of leiomyomas. Rather, management of patients with symptoms of uterine myomas has traditionally been surgical ranging from myomectomy to hysterectomy. Of the 650,000 hysterectomies performed annually in the United States, approximately 27% or 175,000 are performed for uterine myomas.[3] Myomectomy is performed in about 18,000 patients per year. Myomectomy has a recurrence rate of 15% (range, 4% to 59%) and a repeat operation rate of 10% (range, 3% to 21%), and subsequent hysterectomy is required in an additional 1% to 5% of patients.[4, 5]

Although the pathogenesis of myomas is not well established, it has been recognized that fibroid growth and maintenance are stimulated by estrogen and are affected by hormonal cyclic changes.[6] Estrogen and progesterone receptors have been identified in myomatous tissue.[7] Because leiomyomas can be influenced by changes at the estrogen and progesterone receptors, GnRH agonists have been investigated as a potential treatment.

Several pilot and small studies have been reported in which GnRH agonists were evaluated for the treatment of uterine fibroids.[1, 2, 8-11] Potential benefits of GnRH agonist therapy are a reduction in uterine fibroid size and uterine volume, decreased preoperative and perioperative blood loss, and an improvement in operative conditions.

Effect of GnRH agonists on fibroid size

A primary effect of GnRH agonists on uterine fibroids should be to decrease fibroid size. In one study, the effect of daily administration of nafarelin on uterine and myoma size was evaluated in 10 patients with the use of magnetic resonance imaging.[12] After 6

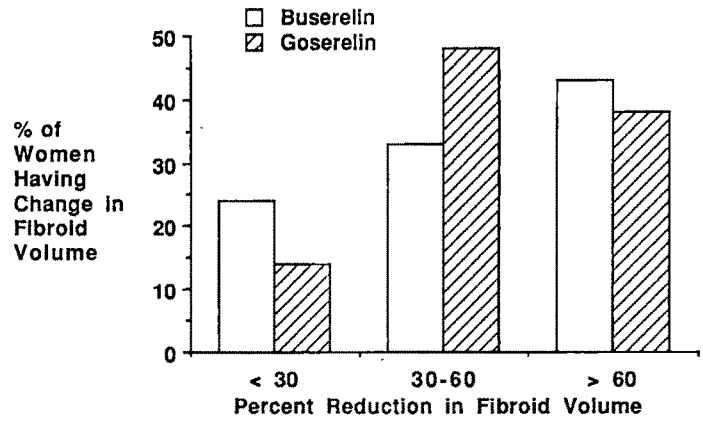

Fig. 1. Proportion of women having a change in fibroid volume from baseline to 6 months after treatment with buserelin (n = 21) or goserelin (n = 21). (Modified from Costantini et al. Eur J Obstet Gynecol Reprod Biol 1990;37:63-9, by permission of Elsevier Science Publishers.)

months of treatment, the size of the largest myoma decreased by a mean of 46% from baseline in 9 of 10 women. Uterine volume decreased by an average of 57% in all treated patients. Of note, both small and large myomas responded to nafarelin therapy, but consistent with other trials, myomas became enlarged again after discontinuation of nafarelin in several women.

In a more recent trial, Costantini et al.[13] compared the effects of 6 months of treatment with intranasal buserelin or subcutaneous goserelin on myoma size. A reduction of more than 30% in myoma volume was seen in 34 of 42 (81%) patients, and no difference was seen between the two GnRH agonists (Fig. 1). As reported in other clinical trials, regrowth of the myomas followed the discontinuation of therapy.[14]

One of the largest trials conducted to date with a GnRH agonist was a multicenter, randomized, placebo-controlled trial in which the effects of intranasal nafarelin on menstrual blood loss and uterine and fibroid volume were evaluated in 166 patients scheduled for elective hysterectomy (Ylikorkala, personal communication). Patients scheduled for hysterectomy for nonmalignant conditions, including uterine fibroids, menorrhagia, or pelvic pain, were evaluated by ultrasound examination. Patients were randomized in a 2:1 ratio to treatment with either intranasal nafarelin, 200 μg twice daily, or placebo for 3 months or until hysterectomy. In patients with fibroids, the total volume of the three largest fibroids decreased by 31% from admission to 3 months in the nafarelin group but increased by 1.2% in the placebo group (p = 0.024; Fig. 2). Assessment of the largest fibroid at the time of surgery showed a decrease in the volume of the largest fibroid with nafarelin compared with placebo (p = 0.055).

All the studies done to date with GnRH agonists show a variable but significant decrease in myoma size; however, in most instances, myomas returned to pretreatment size after discontinuation of GnRH agonist therapy. The reasons for this response within a few months to GnRH agonist therapy have been studied. Pasqualini et al.[15] looked at the effect of a GnRH agonist, decapeptyl, on hormone levels and receptors in uterine myomas and found that myoma tissue was very sensitive to changes in hormone levels. This occurs because myoma tissue has receptors for estrogen and progesterone and thus is affected by both cyclic changes in hormone levels and pharmacologic therapy such as GnRH agonists, which alter hormonal levels.[16] The number of estrogen receptors decreases during the postovulatory phase and is greatest during the follicular phase. Further, estrogen and progesterone receptors are more numerous in submucous than subserosal myomas. This has led to the hypothesis that submucous myomas may respond better to GnRH agonist therapy than large subserosal myomas. In addition, the effect of GnRH agonists on myomas is to decrease cell size and intracellular matrix but without changes in the number of cells. Therefore it is not surprising that after the GnRH agonist is discontinued, myomas return to pretreatment size.

Effect of GnRH agonists on uterine size

GnRH agonists are also known to decrease uterine size. In a prospective randomized trial, Friedman et al.[14] demonstrated a reduction in uterine volume with leuprolide acetate. Eighteen women were randomly assigned to receive monthly intramuscular injections of leuprolide or placebo for 24 weeks. A significant ($p < 0.05$) reduction in uterine volume was noted at 12 and at 24 weeks in the leuprolide group compared with pretreatment volume (Fig. 3). However, uterine volume returned to 88% of pretreatment levels by 3 months after discontinuation of GnRH therapy.

In another large double-blind multicenter trial, leu-

prolide acetate or placebo were administered to 128 women with leiomyomata uteri every 4 weeks for 24 weeks.[17] Mean uterine volume decreased by 45% in patients treated with leuprolide compared with a 5% increase in those given placebo. Uterine volume returned to pretreatment size by 24 weeks after leuprolide was stopped.

The Finnish study that used nafarelin also showed that both the length and volume of the myomatous uteri were decreased significantly ($p < 0.05$) in the nafarelin group compared with the placebo group (Ylikorkala, personal communication). These findings were confirmed during surgery where the uterine weight was measured. There was a significant decrease in uterine weight in the nafarelin group compared with the placebo group in all patients and in the patients with fibroids only. Thus the results from these studies demonstrate that GnRH agonists reduce uterine and myoma size.

Implications of GnRH treatment of uterine fibroids

With a documented reduction in uterine and myoma size, the question becomes "What are the implications of the effects of GnRH agonists in the clinical management of myomas?" One of the potential benefits of preoperative GnRH agonist treatment of uterine fibroids is a reduction in menstrual blood loss. Results

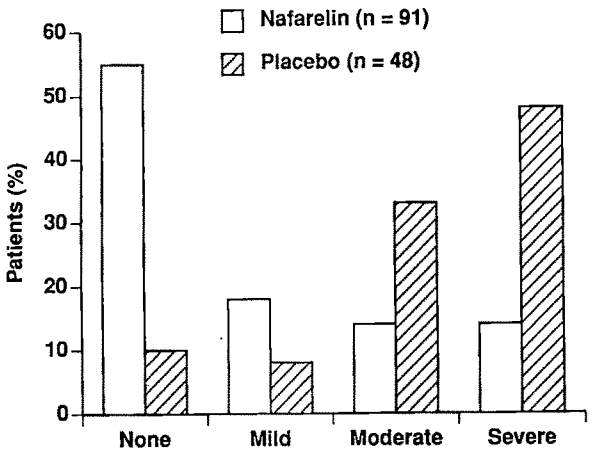

Fig. 4. Severity of menstrual blood loss at 3 months in women treated with nafarelin or placebo before elective hysterectomy (Ylikorkala, personal communication). $p < 0.001$ for nafarelin vs placebo by Cochran-Mantel-Haenszel test.

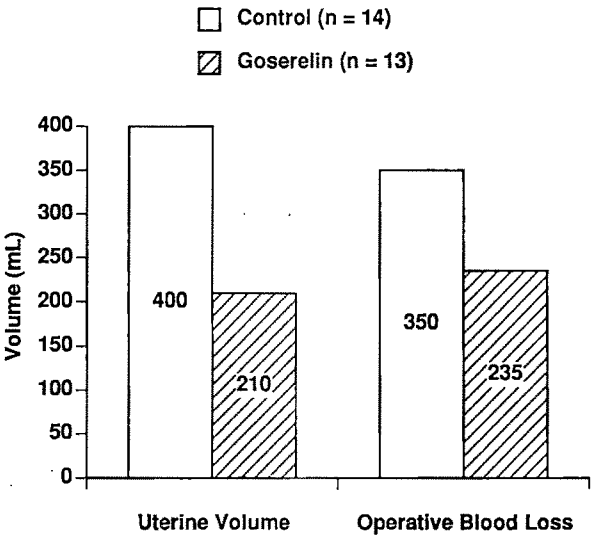

Fig. 5. Uterine volume and operative blood loss in women with symptomatic uterine fibroids treated for 3 months before elective hysterectomy. $p < 0.01$ for goserelin vs placebo by Wilcoxon two-sample test. (Modified from Lumsden MA et al. Lancet 1987;1:36-7.)

from the Finnish study confirm this effect (Ylikorkala, personal communication). In patients with severe blood loss at baseline, 55% of those randomly assigned to nafarelin therapy had no bleeding at the end of the 3-month treatment period compared with 10% of the placebo-treated patients ($p < 0.001$). In contrast, 48% of patients receiving placebo continued to have severe menstrual bleeding at the end of therapy compared with only 14% of patients receiving nafarelin (Fig. 4). In addition, a mean increase of 4.2% in hemoglobin levels was noted before surgery in patients treated with nafarelin compared with a decrease of 2.7% in the placebo group ($p = 0.032$).

In another study, patients were treated with 3.6 mg of subcutaneous goserelin every 28 days for 6 months.[10] In addition to a reduction in myoma and uterine size, there was a reduction in both menstrual blood loss and blood loss at the time of surgery (Fig. 5). Similar findings were reported in the large leuprolide study.[17] In addition to improvement in symptoms in most patients, 37 of 38 patients (97%) with menorrhagia at baseline had resolution by the end of treatment with leuprolide.

The decrease in blood loss and the increase in hemoglobin and hematocrit afforded by GnRH agonist therapy have several potential benefits, although it must be emphasized that prospective randomized studies proving these potential benefits have not yet been performed. The patient's hematocrit level may be sufficient to allow the patient to give autologous blood donations before surgery. Further, the lessened perioperative blood loss may reduce the need for blood transfusion and hysterectomy at the time of surgery. Thus the risks associated with blood transfusion, which are often overlooked or underestimated, may be reduced. Between 8% and 18% of patients require blood or blood products at surgery; the current risk of hepatitis is approximately 8% per transfusion.[5, 18, 19] Other potential advantages from the use of GnRH agonists may result from a reduction of uterine myoma size. These include the use of more conservative surgery; that is, the condition may be managed with myomectomy rather than hysterectomy. Smaller and fewer incisions may result in decreased tissue trauma and increased preservation of normal tissue, possibly reducing adhesion formation after surgery. Other potential advantages are listed in Table I.

Table I. Potential advantages of a reduction in uterine and myoma size by GnRH agonists

Reduced vascularity
• Reduced menorrhagia
• Increased hematocrit and iron
• Autologous donation
• Less operative blood loss
• Reduced risk of blood transfusion
• Reduced risk of hepatitis
Operative technique
• Hysterectomy less likely
• Operative laparoscopy more likely
• Fewer, smaller incisions
• Less tissue trauma
• Less risk of injury
• Pfannenstiel incision more feasible
• Vaginal hysterectomy more feasible
Integrity of uterine cavity
• Hysteroscopic approach
• Avoidance of uterine cavity at laparotomy

Disadvantages of GnRH agonist therapy

Treatment with GnRH agonists is not benign. The known hypoestrogenic side effects are hot flashes and bone loss. About 2% of patients receiving GnRH agonist therapy can experience a very profuse vaginal hemorrhage requiring immediate surgical management.[20] This serious clinical problem has been reported to date only in patients with submucous myomas. The cause of this adverse event is thought to be a reduction in myoma size and a loss of mechanical compression of the vessels within the uterus. Also, painful fibroid degeneration may occur. There is also concern about making the fibroid so small as to avoid detection at the time of surgery.

Some investigators have been concerned that myomas may be reduced to an undetectable size by preoperative GnRH agonist use. Results from a recent trial of buserelin before myomectomy suggested that this phenomenon occurs.[21] In this randomized trial, a 44% decrease in uterine volume was observed during buserelin therapy in eight patients compared with no change in 16 untreated control patients. Intraoperative blood loss and postoperative morbidity did not differ between groups. However, at the 6-month postoperative evaluation, only 2 of 16 (13%) patients in the untreated group had myomas smaller than 1.5 cm in size compared with 5 of 8 (63%) patients in the buserelin group. These data suggest that small myomas may have been missed at the time of surgery because of preoperative treatment with buserelin. The results of this study need to be confirmed by others, and if true, its clinical relevance established.

Strategies for managing uterine myomas

Despite the promising results of studies with GnRH agonists for the treatment of uterine fibroids, surgery remains the treatment of choice. Several different procedures are appropriate including myomectomy by either laparoscopy, laparotomy, or hysteroscopy or hysterectomy by various surgical approaches. However, the use of a GnRH agonist as a preoperative adjunct has some potential benefits to the patient. Preoperative use of GnRH agonists may increase the feasibility of using myomectomy instead of hysterectomy, increase the use of laparoscopic, hysteroscopic, or vaginal procedures, preserve normal uterine tissue, facilitate the operative technique, and reduce blood loss. The choice of therapy will depend on the surgical aspects of treatment, but also on the size and number of myomata, the age of the patient, and the desire to preserve fertility and uterine function.

One innovative strategy for managing uterine fibroids with medical therapy only is to combine the GnRH agonist with an estrogen-progestin combination. In a preliminary trial, five women with leiomyomata uteri were treated with leuprolide for 24 weeks.[22] After 3 months, conjugated estrogens were added on days 1 to 25 and medroxyprogesterone acetate from days 16 to 25. Patients were followed for as long as 2 years. A 49% decrease in uterine volume was seen at 3 months, but no further decrease was seen during the next 2 years. There was also a decrease in vasomotor symptoms, and bone density was preserved. These results were encouraging, but additional data obtained on more patients and a longer duration of study have shown a regrowth of the myomas in some patients taking this regimen. This confirms not only that leiomyomata and myometrium are estrogen sensitive, but suggests that an estrogenic threshold exists for uterine growth. It can be seen that different treatment strategies that use GnRH agonists show promise, but the optimal approach to medical treatment of uterine fibroids is unclear. Further studies, many currently ongoing, will help us understand and use GnRH agonists better in the future.

In conclusion, results from clinical trials have consistently shown the efficacy of GnRH agonists as a preoperative adjunct for reducing myoma and uterine size and preoperative and perioperative blood loss. Uterine myomas are very sensitive to hormonal changes probably mediated through estrogen and progesterone receptors, the likely mechanism by which GnRH agonists can effect changes. Although the role of the GnRH agonists in the management of uterine leiomyoma has not been fully defined, use as a presurgical adjunct may allow preservation of uterine tissue because of removal of smaller myomas and more conservative surgical procedures.

Gonadotropin-releasing hormone agonists: Strategies for managing the hypoestrogenic effects of therapy

Howard L. Judd, MD
Los Angeles, California

Gonadotropin-releasing hormone agonists have been shown to be comparable with danazol for the treatment of endometriosis. These results are important because danazol is associated with a significant number of side effects, particularly androgenic effects, such as weight gain and acne. Although gonadotropin-releasing hormone agonists are associated with hypoestrogenic side effects, such as hot flashes and reversible bone density loss, recent studies suggest that the risk of these side effects may be modified when gonadotropin-releasing hormone agonists are combined with a progestin. These findings suggest that such regimens may further enhance the clinical usefulness of gonadotropin-releasing hormone agonist therapy for endometriosis and other estrogen-mediated diseases. (Am J Obstet Gynecol 1992;166:752-6.)

Key words: Hypoestrogenism, norethindrone, vasomotor symptoms

Gonadotropin-releasing hormone (GnRH) agonists were discovered in the early 1970s and subsequently have been studied extensively for the treatment of a broad range of endocrine disorders, including endometriosis and uterine leiomyomata.[1] Two GnRH agonists, nafarelin and leuprolide, have been approved for the treatment of endometriosis, and clinical investigations with these and other GnRH agonists are ongoing for other indications.

The GnRH agonists were first used clinically in the 1980s. Soon after it was realized that although these potent agents produce important pharmacologic effects, they also were associated with some side effects.[2] GnRH agonists suppress luteinizing-hormone and follicle-stimulating hormone to turn off gonadal production of estradiol and testosterone.[1] Thus the side effects associated with GnRH agonists appear to be linked to the rapid and complete suppression of circulating estrogen induced by GnRH agonists. Prominent among these are typical hypoestrogenic side effects such as hot flashes and vaginal dryness.[3] Of more concern are reductions in bone density. Although some investigators have found no significant loss in bone density,[4] others have found reversible bone density loss,[5] and still others have found the loss to be irreversible.[6] Nevertheless, in many individuals these adverse effects are not considered an obstacle to routine use of GnRH agonists because the overall benefits of treatment are favorable. Moreover, the desire to modify these risks by combining GnRH agonists with other agents has prompted a series of experimental and clinical studies to identify treatment strategies that will ameliorate these side effects.

Of the potential approaches to this situation, two strategies are most promising. One is to first suppress circulating estrogen with a GnRH agonist, thereby inducing control of endometriosis, and then add-back exogenous estrogen in small amounts to reverse some of the unwanted hypoestrogenic effects. The other approach is to administer small amounts of exogenous progestin concurrently with the GnRH agonist in an attempt to circumvent the hypoestrogenic effects altogether.

Pilot studies of add-back regimens of estrogen have yielded promising results, but clinical trials with this approach have been initiated only recently. More widely evaluated has been the concurrent administration of progestins, which has now been studied in several trials. Although these studies have yet to identify a regimen that eliminates side effects while preserving the efficacy of the GnRH agonist, they have demonstrated that this approach is viable and have prompted a more vigorous search for an optimal combination. At my institution, where some of the initial studies in this area were performed, controlled trials have suggested that it is possible to deliver effective but more tolerable doses of GnRH agonists when progestins are used to modify associated adverse effects.

GnRH agonist plus medroxyprogesterone acetate

A pilot study was performed at my institution with the use of medroxyprogesterone acetate in an attempt to modify GnRH agonist side effects.[7] Eight women with endometriosis were studied. Each received a daily subcutaneous dose of a GnRH agonist plus medroxy-

From the Division of Reproductive Endocrinology, Department of Obstetrics and Gynecology, UCLA School of Medicine.
Reprints are not available.
6/0/34760

progesterone acetate, 20 to 30 mg daily for 24 weeks. Patients were evaluated at baseline and at 6 months with laparoscopy and bone density measurements. Objective and subjective hot flash scores were obtained routinely. Results with this combination were compared with results obtained previously in patients treated with a GnRH agonist alone.[8]

Serum estrogen and gonadotropic hormone levels were reduced at 1 month to levels typically seen with a GnRH agonist alone and remained suppressed throughout the course of therapy. Subjective hot flash scores were increased with the combination therapy, but the scores with the GnRH agonist alone were significantly higher during the 6 months of therapy. In addition, objective hot flashes occurred more frequently in patients receiving a GnRH agonist alone than with GnRH agonist plus medroxyprogesterone acetate. In contrast with the effects of a GnRH agonist alone, there was no change in bone density of the distal radius or lumbar spine during treatment with a GnRH agonist plus medroxyprogesterone acetate (Table I).

However, even though ovarian estrogen secretion was reduced to levels seen in castrated women, the regimen failed to significantly reduce symptoms such as pelvic pain. Furthermore, there was no significant improvement in the American Fertility Society score from baseline to 6 months in contrast to a 50% to 60% improvement with the GnRH agonist alone (Fig. 1). Although these results were not expected, they did provide evidence that at least some of the hypoestrogenic effects of a GnRH agonist could be modified with the addition of a progestin. Barbieri et al.[9] found similar results in patients with uterine fibroids. Little or no suppression of fibroid size was observed with the combination of GnRH agonist and medroxyprogesterone acetate.

GnRH agonist plus norethindrone

The reason for the lack of efficacy with a GnRH agonist and MPA is not clear, but it was hypothesized that another progestin with less estrogenic activity may be more effective for reducing hypoestrogenic side effects while maintaining the endometriotic efficacy of the GnRH agonist. In a subsequent study, the GnRH agonist, histrelin, was administered in combination with the 19-nortestosterone derivative, norethindrone.[10] In this study, 10 women with endometriosis were given daily subcutaneous injections of histrelin along with a daily dose of norethindrone that was titrated upward from 0.35 mg to a dose that eliminated vasomotor symptoms. All patients had failed to tolerate or respond to conventional treatment of endometriosis, including danazol, oral contraceptives, conservative surgery, or progestins. Therapy was continued for 24 weeks, and all patients kept diaries beginning 4 weeks before therapy and continuing for 8 weeks after therapy was discontinued. Pain, hot flashes, and additional side effects were recorded and scored in these diaries. Patients also underwent diagnostic laparoscopy before treatment and 4 weeks after the completion of therapy. Bone mineral density was measured before therapy, immediately after therapy, and 24 weeks after treatment. Serum cholesterol and gonadotropin assays were obtained periodically during treatment. The results were compared with 16 patients treated with GnRH agonist alone.[8]

The mean dose of norethindrone was 2 mg during the last 8 weeks of study. A significant reduction in

(From Surrey ES, Gambone JC, Lu JKH, Judd HL. The effects of combining norethindrone with a gonadotropin agonist in the treatment of symptomatic endometriosis. Fertil Steril 1990;53:620-6. Reproduced with permission of the publisher, The American Fertility Society.)

American Fertility Society scores of endometriosis was observed in patients treated with the GnRH agonist plus norethindrone. The mean American Fertility Society score before therapy was 14.6 ± 3.6 and decreased to 6.4 ± 2.0 after therapy ($p < 0.005$). These results were similar to those observed in women treated with a GnRH agonist alone. More important, the reduction in endometriosis score was accompanied by a significant improvement in pain scores. Pain scores were significantly ($p < 0.005$) reduced at 4 weeks, and this effect was sustained throughout therapy. Again, this pattern of response was similar to results achieved with GnRH agonist alone. Thus the efficacy of the GnRH agonist did not appear to be adversely affected by the addition of this progestin.

Interestingly, the combination regimen was associated with a lower incidence of side effects compared with the control group given the GnRH agonist alone. Subjective hot flash scores were reduced with the GnRH agonist plus norethindrone, and the incidence did not increase beyond week 4 (Fig. 2). Objective hot flashes were seen in only 40% of patients at week 4 and 20% of patients at week 20 with the combination. In the control group receiving the GnRH agonist alone, 60% reported hot flashes at week 4, and 80% reported vasomotor symptoms at week 20. The reduction in vasomotor symptoms in the combination regimen group was associated with increasing dosages of norethindrone. Furthermore, the decrease in vasomotor symptoms with GnRH agonist plus norethindrone occurred

despite a reduction in serum estradiol concentrations to levels expected in the castrated woman.

Bone density of the distal third of the radius was not reduced significantly by the GnRH agonist and norethindrone when measured by single-photon absorptiometry. However, bone density of the lumbar spine declined by a mean of 5.6% at 24 weeks using quantitative computerized tomography (Fig. 3). The change appeared to be completely reversed by 24 weeks after discontinuation of therapy, and no significant difference in bone density of the lumbar spine was detectable between baseline and 24 weeks after therapy. Overall, the findings suggest that the amount of bone loss occurring with GnRH agonist therapy may be either reversible or substantially reduced with the addition of norethindrone.

It is also important that the results from this study on bone density changes were supported further by a report from Riis et al.[11] In this study 17 premenopausal women with endometriosis were treated with nafarelin, 400 μg/day, plus norethisterone, 1.2 mg daily for 6 months, and then norethisterone alone for 6 months. The results were compared with two groups of patients; 20 healthy premenopausal women and 9 premenopausal women with endometriosis treated with nafarelin, 400 μg/day alone. Bone density measurements were obtained in at baseline, 6 months, and 6 months after nafarelin therapy was stopped.

In the group treated with nafarelin only, bone density in the distal radius and lumbar spine decreased by 2% to 6% after 6 months of treatment ($p < 0.05$ vs baseline). All values were not significantly different from baseline at the 6-month posttreatment assessment. In contrast, the group treated with nafarelin plus norethisterone had no significant decrease in lumbar spine density compared with control subjects and only a minor decrease in bone density of the distal radius. Also, fasting urinary hydroxyproline, a measure of bone resorption, was unchanged with the combination regimen but significantly ($p < 0.05$) increased with nafarelin alone. Further studies involving double-blind, randomized comparison of women treated with a GnRH agonist plus norethindrone and control subjects treated with a GnRH agonist alone are needed.

In conclusion, 5 to 6 years of experience has been gained studying the effects of adding a progesterone or estrogen-progesterone to GnRH agonist therapy for endometriosis or leiomyomata uteri. This experience has provided some important information. The combination of a progestin and a GnRH agonist has a positive impact on the incidence of postmenopausal symptoms and loss of bone density experienced by patients treated with a GnRH agonist alone. The improvements occur without sacrificing the efficacy of the GnRH agonist. However, these benefits may occur at the expense

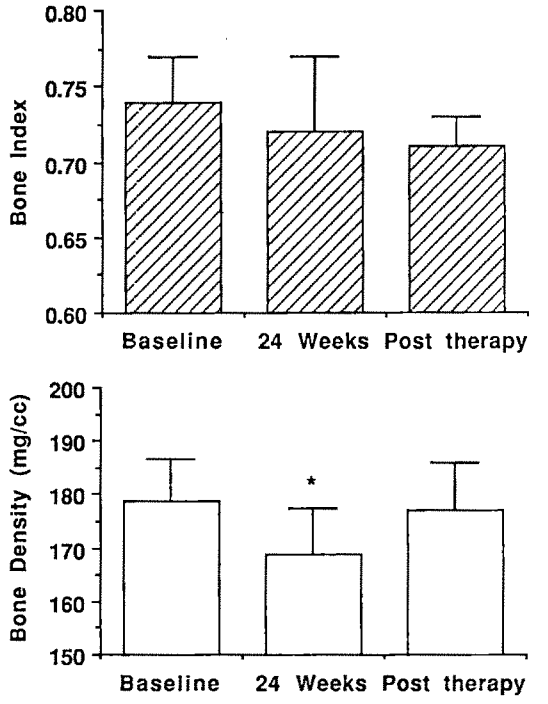

Fig. 3. Bone density measurements of the distal radius *(top)* and lumbar spine *(bottom)* at baseline, after 24 weeks of therapy with a GnRH agonist plus norethindrone, and 24 weeks after therapy. Values are mean ± SE. *$p < 0.05$ vs baseline. (From Surrey ES, Gambone JC, Lu JKH, Judd HL. The effects of combining norethindrone with a gonadotropin agonist in the treatment of symptomatic endometriosis. Fertil Steril 1990;53:620-6. Reproduced with permission of the publisher, The American Fertility Society.)

of an adverse change in the lipid profile; the clinical importance of this change is not known.

Based on these results, the following recommendations can be proposed. In patients with endometriosis in whom a GnRH agonist may be considered, the diagnosis first must be established with laparoscopy. For most patients, initial treatment will be with laser, cautery, or excision. In patients who experience a recurrence of symptoms, consideration should be given to using a GnRH agonist. These agents relieve pain, prevent progression, and delay recurrences of endometriosis.

My recommendation is to add norethindrone, 2.5 mg daily, to the GnRH agonist regimen. This dose of norethindrone will not prevent bone loss but will eliminate vasomotor symptoms that are inherent with GnRH agonist use. Patients who require treatment for longer than 6 months or require a repeat course of therapy with the GnRH agonist should have bone density measurements of the spine or hip obtained before the second course of therapy. The bone density status must be balanced with the patient's severity of symptoms to determine whether to proceed with therapy. If further

therapy is indicated, a higher dose of norethindrone, such as 10 mg daily, could be combined with the GnRH agonist. This higher dose of norethindrone has been found to decrease bone loss in postmenopausal women.[12]

In summary, GnRH agonists are important additions to the management of endometriosis and other reproductive endocrinopathies. Short-term therapy is accompanied by benign but annoying vasomotor symptoms. Long-term therapy is limited by a loss of bone density. Research during the past 5 years has identified alternative treatment regimens that potentially overcome these limitations. Ongoing research will help clarify the role of progestins or estrogen-progestin combinations added to GnRH agonist therapy for the treatment of these conditions.

Gonadotropin-releasing hormone analogs: Update on new findings

Milan R. Henzl, MD
Palo Alto, California

Clinical trials are under way to investigate the optimal use of nafarelin. In one series of studies, the effect of nasal mucosal inflammation and the concomitant use of nasal decongestants on the nasal absorption of nafarelin was evaluated in women with perennial rhinitis. Neither rhinitis nor concomitant therapy with a long-acting nasal decongestant substantially affected the nasal absorption of nafarelin. Other clinical studies are investigating strategies for second treatment of endometriosis or to improve the safety profile of nafarelin. In one trial, a second 3-month treatment course with nafarelin in patients with recurrent symptoms of endometriosis provided substantial pain relief. In another trial, preliminary information indicates that the addition of norethindrone to nafarelin in patients with endometriosis attenuates bone density changes and menopausal symptoms associated with nafarelin treatment. (Am J Obstet Gynecol 1992;166:757-61.)

Key words: Endometriosis, nafarelin, norethindrone, absorption

The intranasal administration of systemically active therapeutic agents is a novel approach to drug delivery, especially for certain chemical classes of drugs such as peptides. The most important conditions for the successful administration of synthetic peptides by the nasal route are their high intrinsic biologic potency and their ability to enter solutions that are easily absorbed by the nasal mucosa.[1] Nafarelin acetate (further referred to as nafarelin), a decapeptide of the class of gonadotropin-releasing hormone (GnRH) agonistic analogs, is one of the compounds that fulfills these conditions.

Nafarelin is now available for general clinical use for the management of endometriosis. It is one of the most potent, if not the most potent, GnRH analog available, exhibiting 200- to 300-fold greater activity than native GnRH. Therefore it is uniquely suitable for intranasal administration. Previous studies have shown that after intranasal administration with 400 μg/day, nafarelin achieves adequate plasma concentrations to produce the therapeutically desired down-regulation of the pituitary-gonadal system.[1-3]

One of the concerns frequently expressed by practicing gynecologists and infertility specialists is about the adequacy of absorption of nafarelin in patients suffering from rhinitis. Therefore it became important to address this question in a series of clinical trials.

Another question relates to the safety and efficacy of repeated treatment with nafarelin in patients with recurrent symptoms of endometriosis. Although nafarelin has been extensively studied for the management of endometriosis, its current recommended use is limited to 6 months. Therefore we have designed studies in groups of patients who had completed one 6-month treatment course and after at least a 6-month post-treatment pause were started on a second course of nafarelin therapy. In addition, we were interested in identifying alternative treatment strategies that would prevent or reduce the incidence of menopausal symptoms and ameliorate bone density changes associated with the therapeutically induced hypoestrogenism.

This preliminary communication reviews results from current studies addressing these questions, namely, (1) nasal absorption of nafarelin in women with rhinitis, (2) efficacy and safety of retreatment with nafarelin, and (3) therapeutic strategies for prevention of menopausal symptoms and bone metabolism changes that accompany GnRH agonist therapy.

Nasal absorption of nafarelin in women with rhinitis

Results from pharmacokinetic studies in normal volunteers have demonstrated that nafarelin is rapidly absorbed into the systemic circulation after intranasal administration and that the absorption rate is constant over time.[5] To examine the effect of inflammation of the nasal mucosa, such as caused by rhinitis, on the absorption of nafarelin, a clinical trial was undertaken in a group of women with perennial rhinitis. The absorption of nafarelin by nasal mucosa in this group of patients was compared with a group of healthy woman volunteers. Nafarelin, 400 μg, was administered intranasally, and plasma levels of nafarelin were measured over an 8-hour interval.

In women with rhinitis, peak nafarelin plasma levels of 1 ng/ml were achieved within 30 minutes and grad-

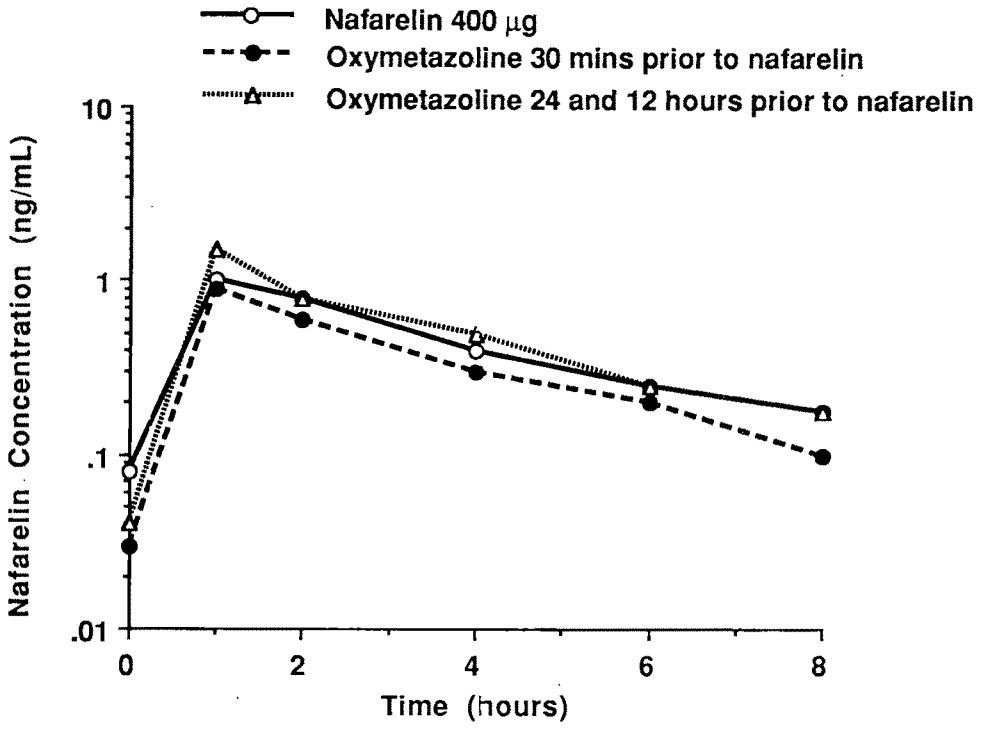

Fig. 1. Plasma nafarelin concentrations after administration of nafarelin, 400 μg, to 12 women. Nafarelin was administered alone, 30 minutes after oxymetazoline, and 12 and 24 hours after oxymetazoline.

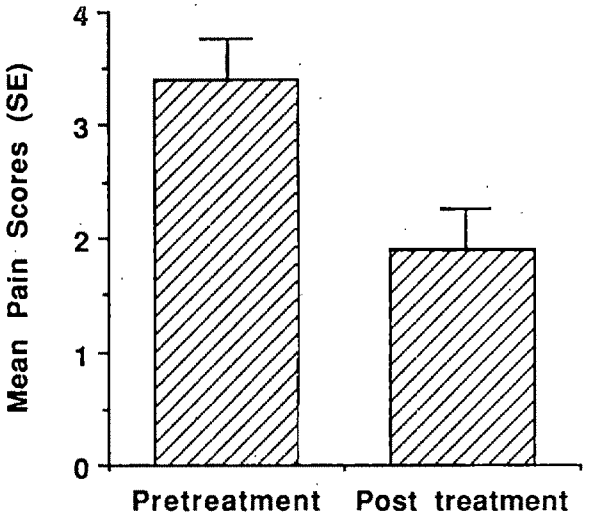

Fig. 2. Mean (±SE) pain scores after 3 months of treatment with nafarelin for recurrent endometriosis.

ually declined with a half-life of about 3 to 4 hours (Fig. 1). This was consistent with the results in normal women; however, nafarelin absorption was slightly enhanced in women with perennial rhinitis compared with the group of normal control subjects. It should be noted that plasma nafarelin levels of 0.5 ng/ml are associated with profound suppression of the pituitary-ovarian system.

In a second trial, the effects of oxymetazoline HCl (Afrin), a commercially available, long-acting decongestant that constricts the small arterioles of the nasal passages, on absorption of nafarelin were evaluated. Oxymetazoline was administered 30 minutes before the administration of 200 μg of nafarelin, and absorption was assessed by repeated measurements of nafarelin plasma levels. In addition, because oxymetazoline is a long-acting product with a duration of action of 12 hours, the absorption characteristics of nafarelin were also studied after the administration of oxymetazoline 12 and 24 hours before the administration of nafarelin.

When oxymetazoline was given 30 minutes before nafarelin, a slight, statistically nonsignificant decrease in nafarelin absorption was noted compared with the nafarelin control group. When oxymetazoline was administered 12 and 24 hours before nafarelin, the absorption of nafarelin was slightly enhanced (Fig. 1).

Thus these results demonstrate that perennial rhinitis and pretreatment with a long-acting nasal decongestant do not appear to affect substantially the nasal absorption of nafarelin. The current recommendations are that nasal decongestants be administered at least 30 minutes after the dose of nafarelin is given.

Efficacy and safety of retreatment with nafarelin

Nafarelin, is currently approved for only one 6-month course for the management of endometriosis.

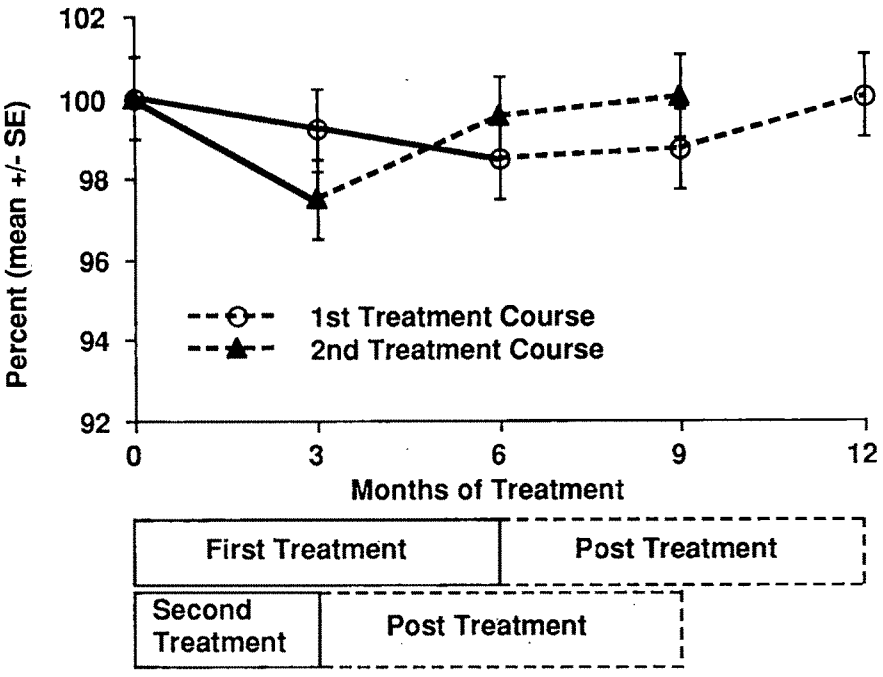

Fig. 3. Changes in lumbar spine bone density assessed by dual-photon absorptiometry during initial 6-month treatment and 6-month follow-up and during 3-month retreatment and 6-month follow-up with nafarelin for recurrent endometriosis.

This is partly because the hypoestrogenic state induced by GnRH agonists is associated with accelerated calcium metabolism in bone tissue and a slight decrease in bone mineral content.[3] The nafarelin-induced hypoestrogenism has little or no effect on bone density changes in compact bone[1,3,4]; rather, it manifests in the trabecular bone of the vertebrae.[3] However, some patients with endometriosis experience a recurrence of symptoms and require treatment with a second course of nafarelin.

In a current clinical trial, patients with recurrent symptoms of endometriosis were treated with a second 3-month course of nafarelin after an initial 6-month course of treatment. The treatment-free period between the first and the second course of therapy was generally 6 months or more. Pain symptoms of endometriosis were evaluated in the same way as in prior studies,[1,3] before the start of nafarelin administration, and at scheduled intervals throughout the study. Changes in bone density of the lumbar spine were measured by dual-photon absorptiometry before the initiation of nafarelin treatment, after completion of the 3-month treatment course, and at the end of the third and sixth months of the posttreatment period. Density of compact bone of the forearm was measured by single-photon absorptiometry. The 3-month regimen was chosen based on results from a previous study that showed that maximal pain relief had already been present at the third month of therapy.[3]

Most patients with endometriosis who received a second course of nafarelin experienced pain relief at the end of the 3-month treatment period. Mean pain scores decreased from about 3.5 before treatment to about 2 after completion of treatment (Fig. 2). As expected, the 3-month retreatment course produced essentially no change in compact bone density as assessed by distal forearm single-photon absorptiometry. Bone density determinations of the lumbar spine showed about a 2.5% to 3% mean decrease during nafarelin therapy; rapid restoration of bone density occurred after withdrawal of therapy (Fig. 3).

Thus it appears that treatment with a second 3-month course of nafarelin for recurrent symptoms of endometriosis affords substantial relief of pain symptoms. In addition, no effect on compact bone was recorded, and the slight loss of lumbar spine density seen during the second 3-month treatment period was rapidly restored after therapy was stopped. These data suggest that a second 3-month treatment course may be effective in patients with recurrent symptoms of endometriosis. Additional trials in a larger patient population will be necessary to confirm these findings.

Evaluation of norethindrone and nafarelin combination therapy on symptoms of hypoestrogenism

We will now discuss the effects of norethindrone on bone density changes and on the incidence of hot

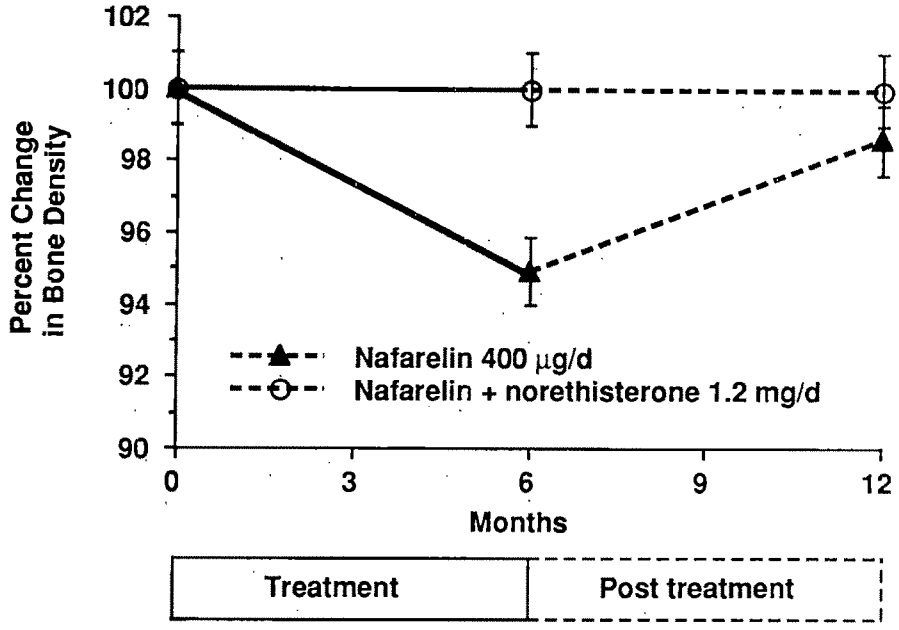

Fig. 4. Changes in lumbar spine bone density assessed by dual-photon absorptiometry with nafarelin, 400 μg/day alone, and combined with norethisterone, 1.2 mg/day. (Modified from Riis et al. Copyright 1990, Journal of Endocrinology and Metabolism.)

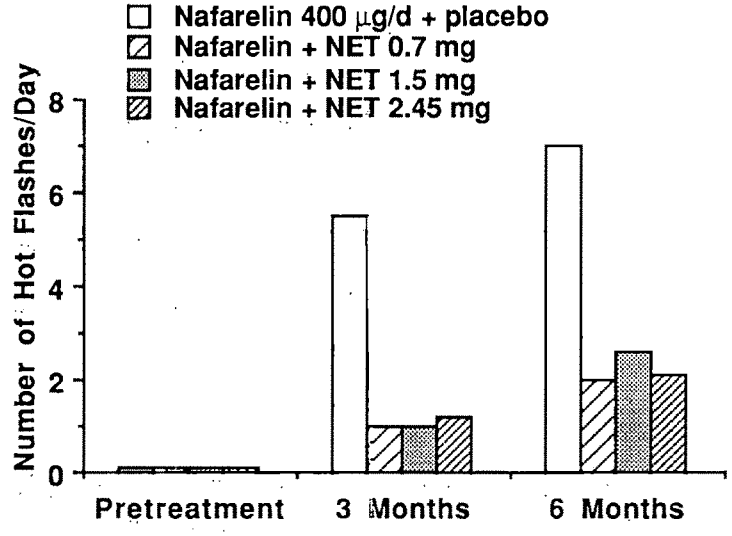

Fig. 5. Average frequency of hot flashes per day in women treated with nafarelin 400 μg/day alone or with combined norethindrone. **NET*, Norethindrone. (Modified from Eldred JM, Thomas EJ. Gynecol Endocrinol 1990;4[suppl 2]:111.)

flashes that are associated with long-term nafarelin treatment.

In the early 1980s, two independent research groups, one led by Mandel et al.[5] and the other by Hart et al.,[6] demonstrated that certain progestogens can counteract the effects of gonadal hormonal deprivation on calcium metabolism in menopausal women. Recently, Riis et al.[4] examined the specific question, does the simultaneous administration of norethindrone and nafarelin exert a bone-sparing effect in patients receiving this therapy for endometriosis. Groups of patients with laparoscopically confirmed endometriosis received either nafarelin alone, 400 μg/day intranasally for 6 months, or norethindrone, 1.2 mg/day orally, in addition to intranasal nafarelin, also for 6 months. Bone density in the lumbar spine was assessed by dual-

photon absorptiometry before treatment, after 6 months of treatment, and after completion of a 6-month posttreatment period. In patients receiving nafarelin alone, bone density in the lumbar spine decreased by an average of 5% at the end of the 6-month treatment period. However, bone density was restored to close to pretreatment levels during the 6-month period after discontinuation of nafarelin therapy. In the group of patients taking 1.2 mg/day of norethindrone in addition to nafarelin, changes in lumbar bone density were attenuated in individual patients, and the average values of trabecular bone density examined at the end of treatment, as well as at the end of the posttreatment observation period, remained unchanged when compared with baseline values (Fig. 4).

The effects of norethindrone on the incidence of hot flashes during nafarelin therapy were studied by Eldred and Thomas.[7] Patients with endometriosis were randomly assigned to treatment with nafarelin, 400 μg/day, and either placebo or norethindrone, 0.7, 1.4, or 2.45 mg daily, and treatment was continued for 6 months. This trial differs from a previously reported trial by Judd et al.[8] in that norethindrone was begun simultaneously with nafarelin.

Patients receiving nafarelin alone averaged about five hot flashes per day after 3 months of treatment, and this increased to about seven episodes daily at the end of the 6-month treatment period (Fig. 5). The addition of norethindrone in the three indicated daily doses substantially decreased the frequency of hot flashes to about two to three per day at the 3- and 6-month evaluations. No dose-response relationship was observed with norethindrone for the doses evaluated in this study.

Thus preliminary data suggest that the combination of nafarelin and norethindrone is associated with beneficial effects on bone density and reduced hypoestrogenic symptoms, such as hot flashes, which are associated with nafarelin treatment. These data are encouraging. Double-blind comparative studies with various doses of progestins administered for 6 months simultaneously with nafarelin are in progress to confirm the results from the described clinical trials.

In conclusion, results from the studies presented here show that nasal absorption of nafarelin is not substantially affected by either perennial rhinitis or concomitant use of long-acting nasal decongestants. Preliminary information from investigations on second treatment with nafarelin for recurrent endometriosis suggests that substantial relief of pain symptoms may be obtained without permanent loss of bone density. Finally, the addition of norethindrone to ameliorate some of the hypoestrogenic effects associated with nafarelin treatment appears to be promising. This research should aid the clinician in selecting optimal therapeutic strategies for the use of nafarelin in the patient with endometriosis.

Bioavailability of nafarelin in healthy volunteers

Melvin D. Chaplin, PhD
Palo Alto, California

The bioavailability of a single dose of intranasal nafarelin was evaluated in 15 healthy female volunteers. Each subject received a 400 μg intranasal and a 25 μg intravenous dose of nafarelin separated by at least 7 days. Blood samples were obtained frequently after each dose for determination of nafarelin plasma levels. After intravenous administration, time to maximum concentration (T_{max}) was 2 minutes, and maximum serum concentration (C_{max}) was 8.2 ± 2.09 (SD) ng/ml. For intranasal nafarelin, mean T_{max} was 18.4 ± 7.9 minutes (range, 5 to 40 minutes), and C_{max} was 2.04 ± 1.29 ng/ml (range, 0.49 to 5.7 ng/ml). Systemic bioavailability of nafarelin ranged from 1.15% to 5.62% and averaged 2.82% ± 1.23%. Nafarelin's bioavailability is adequate to achieve the desired therapeutic effect because of its inherent high biologic potency and its pharmacokinetic properties. Nafarelin is readily absorbed by the nasal mucosa, and therapeutic blood levels are rapidly achieved and maintained for a prolonged period of time. (AM J OBSTET GYNECOL 1992;166:762-5.)

Key words: Bioavailability, intranasal, nafarelin, volunteers

Nafarelin acetate (nafarelin) is a gonadotropin-releasing hormone (GnRH) agonist recently marketed for the treatment of endometriosis. GnRH agonists are rapidly inactivated by gastrointestinal enzymes after oral administration; therefore alternative routes of administration, including intravenous, intramuscular, and subcutaneous injection, are required to achieve the desired therapeutic effect. Because of the inconvenience and poor patient acceptance of multiple daily injections during long-term therapy, nafarelin is formulated for delivery by the intranasal route.

The purpose of this study was to determine the bioavailability of the commercially available intranasal formulation of nafarelin versus an intravenous formulation of nafarelin.

Material and methods

Subjects. This was an open label, randomized, crossover study in 16 healthy female volunteers. Subjects were between ages 21 and 55 years of age and must have been adequately protected from pregnancy with a method other than hormonal contraception. Subjects were excluded if they had a history of allergies or substance abuse, or if any hormones were taken in the 2 months preceding the study. Subjects were asked to avoid drugs that might interfere with the study for 2 weeks before the study. In addition, they were asked to refrain from any medication for 3 days and from alcohol consumption for 2 days before the study and through its completion. The study protocol was reviewed and approved by an institutional review board. Written informed consent was obtained from each subject.

Study design. Before the study, all subjects underwent a complete physical examination and medical history, and each submitted specimens for hematologic study, clinical chemistry, and urinalysis.

The study was conducted on 2 separate days separated by at least 7 days. Subjects were randomly assigned to receive a single dose of nafarelin, 25 μg intravenously, or 400 μg intranasally. Blood (7.5 ml) was obtained at 0, 2, 5, 10, 20, and 40 minutes and at 1, 2, 4, 6, 8, 12, and 24 hours after the administration of each dose of nafarelin. Serum was separated and frozen for analysis of nafarelin concentrations by radioimmunoassay.[1] The lower quantification limit was 0.04 ng/ml; levels below this limit at 0 and 2 hours were set to zero.

Subjects who received intravenous nafarelin were observed for adverse effects for the first 8 hours after administration of nafarelin. Blood pressure and pulse were measured every 15 minutes for 1 hour. Seven days after the final dose of nafarelin, subjects returned for a repeat physical examination and provided specimens for hematology, clinical chemistry, and urinalysis. Information was solicited about any adverse events or intercurrent complaints.

Statistical and pharmacokinetic analysis. Differences between body weight and vital signs at admission and the final examination were analyzed with the two-sided signed rank test. Changes in vital signs from admission to the start of the intravenous dose and from the intravenous dose to time points beyond were also analyzed with the signed rank test. The signed rank test was used to avoid the assumption of normality required for the repeated measures of analysis of variance. Hematologic and clinical chemistry test results

were summarized by the change between normal, low, or high as established from the normal limits of the clinical laboratory.

The following pharmacokinetic parameters were determined by noncompartmental methods: time to maximum serum concentration (T_{max}); maximum serum concentration (C_{max}); and serum half-life ($T_{1/2} = Ln2/\beta$). The elimination rate constant (β) was the magnitude of the slope obtained from linear regression of the natural logarithm (Ln) of serum nafarelin concentrations versus time. Total body clearance (CL) was calculated from the equation: CL = dose/(AUC) 0-inf)* × body weight. Volume of distribution (Vd) was calculated from the equation: $Vd = CL/\beta$.

Area under the curve (AUC) was determined from 0 to 8 hours (AUC 0 to 8) and from 0 to infinity. AUC values were obtained by summing the area segments under the serum concentration/time curves. AUC segments between time points with measurable nafarelin levels were calculated by the trapezoidal rule. AUC segments beyond the last measurable level were obtained by extrapolating along an exponential decay curve with the elimination rate constant β.

Systemic bioavailability (F) of intranasal nafarelin was calculated from the percent ratio of AUC 0-inf/dose for the nasal route versus the intravenous route:

$$F(\%) = \frac{AUC_{nasal}}{AUC_{IV}} \times \frac{Dose_{IV}}{Dose_{nasal}} \times 100$$

Dose-normalized serum levels for intranasal nafarelin were calculated by the equation: Normalized serum level = measured value (ng/ml) × 400 μg/estimated dose (μg), where the estimated dose was calculated from the change in the weight of the spray apparatus before and after administration.

Summary statistics and 95% confidence intervals were obtained for all pharmacokinetic parameters. Statistical analysis of these parameters was based on a two-period crossover design.[2] The significance level was 0.05.

Results

Sixteen subjects were randomly assigned to the study. Serum nafarelin data were incomplete in one subject because of interference from an endogenous substance with the radioimmunoassay of samples after both intravenous and intranasal nafarelin. This subject's data were excluded from pharmacokinetic analysis. For the subjects included in the analyses, the average age was 27.7 years (range, 23 to 38 years), the average height was 164.4 cm (range, 151 to 178 cm), and the average weight was 58.8 kg (range, 50 to 70 kg).

Estimated delivery of nafarelin dose. Two sprays from the intranasal apparatus were estimated to deliver 124% ± 51% of the target dose of nafarelin, 400 μg (i.e., 497 ± 203 μg). Serum level data were normalized to the target dose using the estimated dose; however, this did not decrease the variance of calculated pharmacokinetic parameters. Pharmacokinetic parameters calculated from the measured values are presented.

*AUC 0-inf = Area under the curve from 0 to infinity.

Table I. Pharmacokinetic values obtained after administration of single doses of intranasal and intravenous nafarelin to 15 healthy female volunteers*

Parameter	*Intranasal (400 μg)†*	*Intravenous (25 μg)*
T_{max} (min)	18.4 ± 7.9	2.0 ± 0
C_{max} (ng/ml)	2.04 ± 1.29	8.20 ± 2.09
Half-life (hr)	4.4 ± 1.8	3.9 ± 1.4
Clearance (ml/min × kg)	ND‡	0.93 ± 0.17
Volume of distribution (L/kg)	ND	0.31 ± 0.11
AUC 0 to 8 hr (ng × hr/ml)	3.35 ± 1.55	6.74 ± 1.28
AUC 0 to infinity (ng/ml × hr)	4.05 ± 1.82	7.90 ± 1.51
Bioavailability (%)	2.82 ± 1.23	100

*All values are mean ± standard deviation.
†Estimated dose was 497 μg.
‡Not determined.

Pharmacokinetic results. Pharmacokinetic values obtained from intranasal and intravenous administration of nafarelin are shown in Table I. After intravenous administration, T_{max} was 2 minutes, and C_{max} was 8.2 ± 2.09 ng/ml. For intranasal nafarelin, mean T_{max} was 18.4 ± 7.9 minutes (range, 5 to 40 minutes), and C_{max} was 2.04 ± 1.29 ng/ml (range, 0.49 to 5.7 ng/ml). Normalization of the C_{max} values to the 400 μg dose of intranasal nafarelin did not reduce the variability of the data. Mean measured serum levels for intranasal and intravenous nafarelin over the observation period are illustrated in Fig. 1.

The serum nafarelin half-life was similar after intranasal and intravenous administration. For the intranasal dose, half-life ranged from 2.9 to 10 hours (mean, 4.4 ± 1.8 hours). For the intravenous dose, the half-life ranged from 2.2 to 7.8 hours (mean, 3.9 ± 1.4 hours). The total AUC after intravenous administration ranged from 5.04 to 10.56 ng/ml × hours (mean, 7.90 ± 1.51), with a coefficient of variation of 19%. After intranasal administration, the total AUC ranged from 1.37 to 8.15 ng/ml × hours (mean, 4.05 ± 1.82), with a coefficient of variation of 45%. When the total AUC was normalized to the 400 μg dose based on the estimated dose, the total AUC ranged from 1.52 to 7.59 ng/ml × hours; again, normalization did not reduce the variability of data.

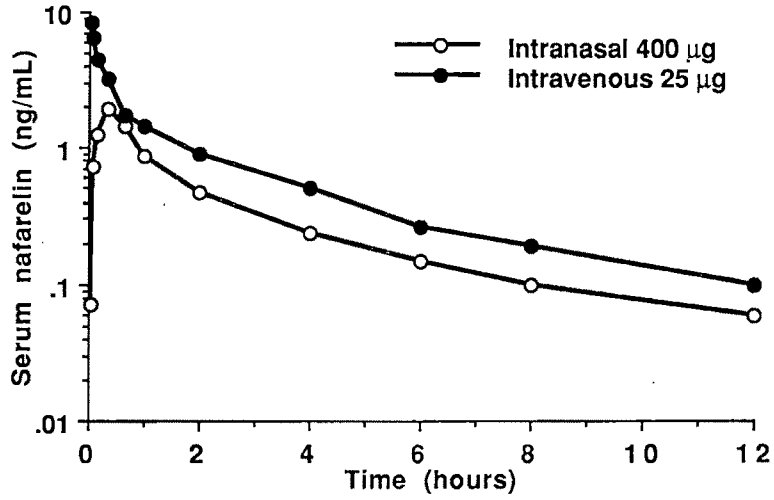

Fig. 1. Mean serum concentrations of nafarelin after a single 400 μg intranasal or 25 μg intravenous dose administered to 15 healthy female volunteers. Estimated delivered intranasal dose was 497 ± 204 μg.

Total body clearance and volume of distribution were determined only for the intravenous nafarelin dose. Clearance ranged from 0.67 to 1.38 ml/min × kg (mean, 0.93 ± 0.17), and volume of distribution ranged from 0.18 to 0.47 L/kg (mean, 0.31 ± 0.11).

The systemic bioavailability of intranasal nafarelin was calculated from measured total AUC values for intravenous and intranasal nafarelin. Systemic bioavailability ranged from 1.15% to 5.62% and averaged 2.82% ± 1.23%.

Comment

The results of this study document the rapid absorption and bioavailability of nafarelin after intranasal administration of a single 400 μg dose. The average T_{max} was 18.4 minutes, and the average C_{max} was 2.04 ng/ml. The average systemic bioavailability was 2.82%.

These results are comparable with those obtained previously in humans and animals.[3, 4] Chan et al.[4] evaluated the bioavailability of intranasal nafarelin relative to subcutaneous nafarelin in six men and observed a mean value of 3.6% ± 1%.[4] A wide interpatient variation in serum levels was noted with intranasal nafarelin in the present study; however, a considerable although lesser variation occurred in serum levels after intravenous administration.

After oral administration, GnRH agonists undergo rapid enzymatic inactivation and are rendered biologically inactive.[5] Thus GnRH agonists must be administered by intravenous, intramuscular, or subcutaneous injection or by nasal, vaginal, or rectal routes.[6] However, intranasal or subcutaneous methods are the only practical and convenient routes of administration for prolonged daily use. Nafarelin is ideal for intranasal administration because of its high biologic potency and long plasma half-life (mean, 4.4 hours). Absorption after intranasal administration is found to be reliable but variable. These properties permit the achievement of desired therapeutic responses by the administration of relatively low doses with a twice-daily regimen.

Intranasal administration of other GnRH agonists is less desirable because of a short half-life or low biologic potency.[7] For instance, tryptorelin, buserelin, and histrelin have biologic potency that is 100-fold greater than native GnRH.[6] However, the plasma half-lives of tryptorelin, buserelin, and histrelin range from 50 to 75 minutes. This necessitates administration of multiple daily doses, when given intranasally to achieve the desired therapeutic response. In contrast, leuprolide has a longer half-life of about 3 hours, but its low biologic potency (15-fold greater than native GnRH) and poor intranasal bioavailability (<5%) require administration of large daily doses to achieve a therapeutic response.[7] One investigator failed to obtain a therapeutic response with 1600 μg/day of intranasal leuprolide in patients with uterine fibroid disease.[8]

The effects of nasal congestion or concurrent use of topical decongestants on the nasal absorption of nafarelin have recently been studied.[9] Perennial rhinitis or use of a nasal decongestant were found to have no significant effect on nasal absorption of nafarelin. These results are consistent with other studies, which showed that nasal absorption of GnRH agonists is unaffected by nasal congestion possibly because of the large surface area of the nasal mucosa.[6] It is recommended that topical decongestants not be used for 30 minutes after intranasal administration of nafarelin.

The results from this study confirm the feasibility of the intranasal route for the administration of nafarelin. Although the systemic bioavailability of intranasal na-

farelin is variable and relatively low, results from large-scale clinical trials have confirmed the clinical efficacy of this formulation for the long-term treatment of endometriosis.[10] Intranasal administration represents a reliable delivery method and convenient dosage route that is well accepted by patients requiring prolonged treatment.

LETTERS TO THE EDITORS

Intravenous immunoglobulins in postpartum, persistently severe HELLP syndrome: A safe alternative to plasma exchange?

To the Editors: We read with great interest the recent article by Martin et al. (Martin JN Jr, Files JC, Blake PG, et al. Plasma exchange for preeclampsia. I. Postpartum use for persistently severe preeclampsia-eclampsia with HELLP syndrome. AM J OBSTET GYNECOL 1990;162:126-37). The efficiency of plasma exchange in seven well-documented cases actually appears to be convincing because it had already been suggested in some anecdotic cases[1]; however, we would like to draw attention to the risks of plasma-transmitted infections such as non-A, non-B hepatitis; we suggest that intravenous immunoglobulins might be an attractive alternative treatment.

Lian et al.[2] have shown that the immunoglobulin G present in normal adult plasma inhibits the platelet aggregating activity in thrombotic thrombocytopenic purpura plasma and may be partially responsible for the success of plasma infusion therapy in thrombotic thrombocytopenic purpura. The efficiency of immunoglobulins has actually been reported in the treatment of refractory thrombotic thrombocytopenic purpura.[3] Because severe preeclampsia seems to share some common pathophysiologic mechanisms with thrombotic thrombocytopenic purpura[1-4] (as is emphasized by Martin et al.), it appears logical to test the effects of intravenous immunoglobulins in postpartum, persistently severe HELLP (hemolysis, elevated liver enzymes, and low platelet counts) syndrome to avoid the inherent risks of plasma infusion.

Reply

To the Editors: We appreciate the letter from Pourrat about our article. We, too, have concerns regarding the use of human blood products and the potential for transmission of blood-born infections.

We initially chose plasma as our replacement fluid on the basis of the clinical similarity of the HELLP syndrome and thrombotic thrombocytopenic purpura. Our own studies have demonstrated a marked alteration of the von Willebrand factor multimer composition in this syndrome. Plasma exchange is effective in removing these complexes or adding an antiaggregating component from normal plasma.

Case reports suggesting efficacy of intravenous immunoglobulin preparations are difficult to evaluate in refractory cases of thrombotic thrombocytopenic purpura because of multiple modes of therapy. In occasional patients with chronic relapsing thrombotic thrombocytopenic purpura, intravenous immunoglobulin G has not been effective in reversing the process.[1]

This subgroup of patients (HELLP) with plasma-responsive microangiopathic hemolytic processes may very well be suitable for a study of the potential efficacy of intravenous immunoglobulin G.

Applicability of the Poiseuille equation to umbilical artery velocimetry

To the Editors: We read with interest the article by Wright and Ridgway (Wright JW, Ridgway RE. Sources of variability in umbilical artery systolic/diastolic ratios: implications of the Poiseuille equation. AM J OBSTET GYNECOL 1990;163:1788-91). They applied the Poiseuille equation to the umbilical artery and found that in their selected study population the systolic/diastolic ratios obtained were normally distributed. Two points should be taken into consideration when analyzing the results:

1. The applicability of the Poiseuille equation to the circulation depends on several conditions[1]: (a) the fluid is homogeneous; (b) the fluid does not slip at the wall; (c) the flow is laminar; (d) the rate of flow is steady and is not subject to acceleration and deceleration; (e) the tube is long compared with the region being studied; and (f) the tube is rigid, and its diameter does not vary with the internal pressure.

In the umbilical artery, because the flow is pulsatile, conditions c, d, and f are not satisfied.

2. With continuous-wave Doppler it is not possi-

ble to locate the sampling site; however, Doppler studies[2-4] have pointed out the effect of sampling site on Doppler ratios and suggested uniform measurement techniques (e.g., choosing the placental end of the cord).

Reply

To the Editors: We appreciate Degani's interest in our article. We did not intend to imply that the Poiseuille equation is an adequate model for describing the complex flow dynamics of the umbilical circulation. Rather we sought to determine whether the elements in the Poiseuille equation provide clues to factors affecting umbilical artery resistance as measured by the systolic/diastolic ratio.

As noted in our comments, we recognize that continuous-wave Doppler does not permit selection of sampling site along the cord. We initially chose the continuous-wave Doppler system because these devices are commonly available clinically. The studies to which Degani refers had not been published at the time our investigation began. We agree that use of a uniform sampling site should reduce the variability in systolic/diastolic ratios.

Erythromycin, motilin, and meconium

To the Editors: I read with interest the paper by Eschenbach et al. (Eschenbach DA, Nugent RP, Rao AV, et al. A randomized placebo-controlled trial of erythromycin for the treatment of *Ureaplasma urealyticum* to prevent premature delivery. Am J Obstet Gynecol 1991;164:734-42). Erythromycin is a potent agonist of motilin,[1] which in turn is associated with antenatal passage of meconium by the fetus[2] and fetal distress.[3] Is it therefore possible that long-term therapy with erythromycin for up to 9 weeks of pregnancy could increase the incidence of meconium passage with its attendant sequelae? I note that, although there were no reported differences in the erythromycin-treated group, no mention was made of meconium liquor. It is also of interest that in the same issue of the Journal meconium staining of the amniotic fluid is proposed as a marker for intraamniotic infection (Romero R, Hanaoka S, Mazor M, et al. Meconium-stained amniotic fluid: a risk factor for microbial invasion of the amniotic cavity. Am J Obstet Gynecol 1991;164:859-62). *Ureaplasma urealyticum* is noted to be the most prevalent microorganism found in the patients studied; is it possible that some of these patients had been treated with erythromycin, thereby increasing the incidence of meconium passage via the motilin-like action?

Peter Danielian, MD

Department of Obstetrics and Gynecology, Charing Cross and Westminster Medical School, West London Hospital, Hammersmith Road, London W6 7DQ, England

Reply

To the Editors: We have reviewed the data available on meconium staining of amniotic fluid and aspiration syndrome in the newborn from our erythromycin clinical trial. There is no evidence to support the hypothesis that erythromycin increased either the presence of meconium staining of the amniotic fluid (18.9% in the erythromycin group vs 21.0% in the placebo, $p = 0.37$) or the presence of meconium aspiration syndrome (0.69% in the erythromycin group vs 0.36% in the placebo, $p = 0.68$) in women enrolled in the *Ureaplasma* arm of the clinical trial.

The data from the other arms of the clinical trial (treatment of women with *Chlamydia,* Group B streptococcus, or both with erythromycin) in which an additional 1200 women were enrolled were also reviewed. The results showed a similar lack of evidence (20.1% meconium staining in the erythromycin group vs 18.6% in the placebo, $p = 0.49$; 0.81% meconium aspiration in the erythromycin group vs 1.45% in the placebo, $p = 0.42$) for an erythromycin risk.

The possibility of an association of *Ureaplasma urealyticum* with meconium staining or aspiration syndrome cannot be addressed in the clinical trial reported in our article because the test results of all of the women we studied were positive for the presence of *Ureaplasma.* However, in the same issue of the Journal we also

reported the results of the observational study for women with *Ureaplasma* compared with women without *Ureaplasma* (Carey JC, Blackwelder WC, Nugent RP, et al. Antepartum cultures for ureaplasma urealyticum are not useful in predicting pregnancy outcome. AM J OBSTET GYNECOL 1991;164:728-33). In the observational study no association of *Ureaplasma* with either meconium staining (19.0% in the *Ureaplasma*-positive women vs 19.3% in the *Ureaplasma*-negative women, $p = 0.71$) or aspiration syndrome (1.21% vs 0.89%, $p = 0.12$) was found.

It should be noted that the dose of erythromycin used in our study was lower (333 mg three times each day), but the duration was longer (6 to 10 weeks) than that normally used in pregnancy. The protocol also called for the termination of treatment at the end of 35 weeks' gestation, making it less likely that we would find a lingering effect of erythromycin in term or postterm infants, in whom the risk for meconium-related problems is greatest.

We hope that this additional information will help to allay the concerns raised in Danielian's letter.

Hypothermia revisited

To the Editors: The "revisit" of Hazan et al. (Hazan J, Maag U, Chessex P. Association between hypothermia and mortality rate of premature infants—revisited. AM J OBSTET GYNECOL 1991;164:111-2) to the association between hypothermia and the mortality rate of premature infants struck us as being flaw-ridden in design and superficial in result. Hypothermia is defined as a core temperature of <35° C. Axillary temperatures approximate core temperature. However, 5 minutes with the mercury bulb deep in the axilla are required to obtain repeatable equilibrium temperatures within 0.1° C.[1] Axillary temperatures should be used only when no obvious thermal problem exists.[2] Thus although axillary temperature monitoring is acceptable for routine clinical use, it is not the optimal method of collecting scientific data about hypothermic infants. Furthermore, the investigators did not indicate whether they used a regular clinical thermometer, which is incapable of measuring temperatures in the hypothermic range, or a special thermometer capable of accurately measuring body temperatures lower than 35° C.

Although Hazan et al. detail the mean admission temperatures of the infants, no information is supplied as to the severity of hypothermia in the cooled infants. Thus included in the group with axillary temperatures <35° C may be severely chilled babies with body temperatures of, say, 30° C, and also minimally cold infants with body temperatures of, say, 34.5° C. The outcome of these two extremes could be very different. No details are supplied regarding other indexes of illness that most certainly must have existed and undoubtedly contributed to the mortality. This is especially true in the >1000 gm birth-weight group.

Controversy exists as to the optimal method of rewarming hypothermic infants: rapid rewarming or the more conventional slow rewarming. We[3] have shown that a combination of neonatal intensive care plus rapid rewarming under a radiant warmer resulted in minimal mortality even in small, severely chilled premature infants. Unfortunately, Hazan et al. give no information regarding their therapeutic approach, which may well have affected the infants' outcome.

In spite of these caveats it should be pointed out that Hazan et al. did demonstrate that hypothermia in infants weighing >1000 gm was associated with increased mortality. In the <1000 gm group the mortality was >50%; the severity of prematurity and its attendant problems outweighed the contribution of hypothermia. Thus to imply that hypothermia is not a contributing factor to mortality in most premature infants is misleading, and the data of Hazan et al. cannot serve as a basis for medical revisionism.

Michael Kaplan, MB, ChB, and
Arthur I. Eidelman, MD

Department of Neonatology, Shaare Zedek Medical Center, P.O. Box 3235, Jerusalem 91031, Israel

Reply

To the Editors: Kaplan and Eidelman provide us with the opportunity to expand on our retrospective analysis of body temperature on admission in a neonatal unit. That article was kept succinct to remain within the editorial limits of a brief clinical observation. The working definition of hypothermia ranges widely; we chose a priori a value within that range. In our unit skin temperatures are used in everyday practice to avoid trauma; therefore a skin temperature of <35° C was selected as a cut-off point for hypothermia. Temperatures <35° C were indeed read on an electronic thermometer. Among babies reported as having hypothermia on admission, skin temperatures were in the range 32.0 to 32.9° C in two patients, 33.0 to 33.9° C in six patients, and 34.0 to 34.9° C in the others. Five of eight infants with temperatures <34.0° C died. The association between hypothermia and neonatal mortality was revisited (and not revised) because once again it was verified in premature infants with birth weights ranging from 1000 to 1500 gm. Kaplan and Eidelman call our attention to the possibility that the absence of such an association in the more fragile infants (750 to 999

gm) could be caused by methodologic considerations and the immaturity of the thermogenic capacity. That point is well taken. However, we have to consider that this well-known observation might be merely an association for which it is difficult to prove a cause-and-effect relationship because of numerous confounding factors.

Preeclampsia, von Willebrand factor antigen, and endothelial cells

To the Editors: I read with interest the article by Roberts et al. (Roberts JM, Taylor RN, Musci TJ, et al. Preeclampsia: an endothelial cell disorder. AM J OBSTET GYNECOL 1989;161:1200-4), the letter by Liston and Kilpatrick (Liston WA, Kilpatrick DC. Preeclampsia—an endothelial cell disorder plus "something else"? AM J OBSTET GYNECOL 1990;163:1365-6), and the reply by Roberts and Taylor (Roberts JM, Taylor RN. Reply. AM J OBSTET GYNECOL 1990;163:1366) regarding preeclampsia as an endothelial cell disorder. As our colleagues in Edinburgh and San Francisco discussed, the cause of preeclampsia may involve immunologic, genetic, or cytotoxic factors. Interest in the endothelial cell and its specific product, von Willebrand factor, are evident. Although I spend little time on obstetrics these days I offer the following observations, which may help us to understand preeclampsia.

The use of von Willebrand factor antigen (vWF:Ag) as a tool in the diagnosis and staging of inflammatory vasculitis is becoming established.[1] Although it may be assumed that very high levels of vWF:Ag are indicative of injury or damage to the endothelium, vWF:Ag levels rise normally in the acute phase response and after exercise.[2, 3] Hypertension in the rat and in the human being can also induce an increase in vWF:Ag, but serum from hypertensive patients was not found to be cytotoxic.[4] The importance of hypertension has recently been underlined[5] with the finding of impaired release of endothelial-derived relaxing factor by endothelial cells from hypertensives.

Immune complexes have long been suspected of some role in vasculitis and, some would say, preeclampsia. With an isotope release assay, serum from patients with rheumatoid vasculitis was cytotoxic to endothelial cells in vitro. Cytotoxicity correlated with immune complexes, vWF:Ag, and inversely with the fourth component of complement. This suggested that high levels of immune complexes and complement activation in these diseases may act to injure endothelial cells, which in turn release vWF:Ag.[6] The cytokine tumor necrosis factor[7] has also been shown to be cytotoxic to endothelial cells in vitro.

I hope some of these issues may be of value in determining the nature of the "something else." It may be that some combination of hypertension, immune complexes, cytokines, and cytotoxic endogenous factors act on endothelial cells to induce the changes that accumulate to cause preeclampsia.

Reply

To the Editors: We appreciate Blann's interest and comments and are pleased to learn of his studies of endothelial cell injury in hypertension and vasculitis. Certainly this work is very relevant to our hypothesis that maternal vascular endothelial cell injury or activation mediates many of the pathophysiologic features of preeclampsia. Blann's suggestions about von Willebrand factor expression and immune complexes in preeclampsia deserve further comment. Redman et al.[1] were the first to report elevated levels of von Willebrand factor (factor VIII–related antigen) in the plasma of patients with preeclampsia, an observation that has supported the concept of endothelial cell injury or activation in this syndrome. In our initial report,[2] which showed that preeclamptic sera caused increased sodium chromate Cr 51 release from umbilical vein endothelial cells in vitro, we considered the possibility that the observed cytotoxic effect might be mediated by circulating antiendothelial autoantibodies in these patients. Using immunoblotting techniques, we were unable to demonstrate specific antiendothelial autoantibody activities in the sera of women with preeclampsia relative to those of matched controls.

The pitfalls of this approach, however, include the requirements for relatively high-affinity antibodies and their recognition of cognate antigens after denaturation and electrophoretic separation. Indeed, using a more

sensitive whole cell enzyme-linked immunosorbent assay technique, Rappoport et al.[3] did demonstrate the presence of elevated antiendothelial antibody titers in a subpopulation of women with severe preeclampsia. As Blann indicates, similarities between the pathophysiologic features of preeclampsia and rheumatoid vasculitis may provide clues to their causes. The solution of the pathogenesis of preeclampsia and other enigmatic diseases mandates such intellectual contributions from the many disciplines of modern biomedicine.

Comment on fetal breathing movements after premature rupture of membranes

To the Editors: We read with great interest the article by Roberts et al. (Roberts AB, Goldstein I, Romero R, Hobbins JC. Fetal breathing movements after premature rupture of membranes. AM J OBSTET GYNECOL 1991;164:821-5). Their study used videotapes of real-time ultrasonography of 30 minutes' duration to study fetal breathing and trunk movements in patients of 24 to 34 weeks' gestational age after membranes were ruptured.

In 1988 we published a prospective case-control study on the effect of third-trimester premature rupture of membranes on fetal breathing movements.[1] Our patients' gestational ages were 28 to 41 weeks. During a 30-minute biophysical profile test there was a significant decrease in breathing movements after premature rupture of membranes in otherwise uncomplicated pregnancies (90% vs 65%). Fetal body movements were not changed (97% vs 94%).

Among the patient group in which amnionitis, neonatal infection, or antepartum fetal distress was later detected the incidence of fetal body movement was decreased to 69%. These results agree with the study of Roberts et al.; however, in that study Table I indicated that the time incidence of fetal breathing movements increased with increased fetal age, from 2.6% at 24 to 28 weeks' gestation to 13.3% at 31 to 34 weeks. In our study there was no difference found in the incidence of fetal breathing activity between preterm (28 to 36 weeks) and term pregnancies. This information is especially important because most biophysical profile tests are done at >28 weeks' gestation.

In conclusion, our results complement the study of Roberts et al. in regard to the clinical interpretation of biophysical profile. Fetal breathing movements during 30 minutes of observation decreased or were absent because of premature rupture of the membranes.

It would be interesting to know the incidence of patients with absent breathing movements in the study of Roberts et al.

Asko Kivikoski, MD, and Erol Amon, MD

Reply

To the Editors: I was interested to read the comments by Kivikoski and Amon. I acknowledge the work they have done in this field and that in 1988 they reported that patients with premature rupture of membranes and no complications had less chance of having 60 seconds of continuous breathing on a biophysical profile than normal controls.

Kivikoski and Amon are concerned about the impact of these findings on interpretation of the biophysical profile. A recent article[1] compared measurement of total fetal activity (fetal breathing plus fetal movement) with biophysical profiles in 64 patients with premature rupture of membranes. All had amniocentesis performed to diagnose infection. Measurement of total fetal activity proved to be better than biophysical profile in detecting intraamniotic infection. The problem seems to be that the sensitivity in the biophysical profile with regard to movements is set at too low a level, and analysis of the amount of movement performed in 30 minutes together with the amount of breathing gives a better measure of fetal well-being.

Kivikoski and Amon asked about the incidence of patients with absent breathing movements in our study. This incidence depends on the gestation, but overall between 24 and 34 weeks, approximately 20% of patients studied with premature rupture of membranes had completely absent fetal breathing movements during a 30-minute recording.

The natural history of thrombocytopenia associated with preeclampsia

To the Editors: Katz et al. are to be congratulated on their fine article. (Katz VL, Thorp JM Jr, Rozas L,

Bowes WA Jr. The natural history of thrombocytopenia associated with preeclampsia. AM J OBSTET GYNECOL 1990;163:1142-3) Although numerous papers have been written regarding the diagnosis, frequency, treatment, and complications of HELLP syndrome (hemolysis, elevated liver enzymes, and low platelet count), very few authors have addressed the important issue of the time frame of recovery.

I was surprised by the authors' finding that "bypostpartum day 4, 59 of 61 women had rising counts and all but four women had counts >100,000/mm³." Further, the authors noted that in one of these four patients, sepsis, adult respiratory distress syndrome, and disseminated intravascular coagulation were present and presumably were the cause of the prolonged thrombocytopenia.

In contrast a recent paper by Martin et al.[1] showed that for patients with platelet counts falling below 50,000/mm³, only 80% had recovered to >100,000/mm³ by day 4, and <95% of those with nadirs in platelet count between 50,000 and 100,000 had platelet counts >100,000 by day 4. The experience of Martin et al. is similar to ours; of 41 patients with HELLP syndrome and platelet counts falling below 80,000, eight (19%) had platelet counts below 100,000/mm³ by day 4, and two still had platelet counts below 100,000 by day 6.

Katz et al. do not give the mean platelet count among their 61 patients with HELLP syndrome; among our patients the mean lowest platelet count was 39,000 ± 11,200. The mean peak aspartate aminotransferase level was 521 ± 415 IU/L, and the mean peak lactic dehydrogenase level was 1103 ± 597 IU/L. These figures seem comparable to the values given by Martin et al.[1]

Martin et al.[1] showed a significant difference in recovery time depending on the platelet nadir, with longer recovery times for patients whose platelet counts fell below 50,000. I speculate that the reason for the higher rate of recovery among the patients of Katz et al. as opposed to the series of Martin et al. and our own series may relate to differences in disease severity.

Although it is critically important to search for alternative explanations for thrombocytopenia in all patients with HELLP syndrome, our experience is at odds with the conclusion of Katz et al. that "if a patient with preeclampsia does not have a [platelet] . . . count approaching 100,000/mm³ by postpartum day 4 in the absence of any other pathologic conditions, she is beyond the expected time course of thrombocytopenia associated with preeclampsia."

Documentation of high-molecular-weight dextran (Hyskon) solution entering the serum during hysteroscopy

To the Editors: I have read in the surgical literature of cases of noncardiogenic pulmonary edema and coagulopathy[1,2] during hysteroscopy. I provided anesthesia for a patient who had this syndrome,[3] and the cause remained unclear. The recommended dose of high-molecular-weight dextran (Hyskon) solution is <500 ml; however, complications occurred with this volume.

Hyskon hysteroscopy solution continues to be widely used to distend the uterine cavity and visualize its surfaces during diagnostic and therapeutic hysteroscopy. We evaluated the relationship between the amount of Hyskon solution used, the instillation pressures in the uterine cavity, and the serum levels of Hyskon solution. It is my belief that Hyskon solution is absorbed or injected during hysteroscopy, causing pulmonary edema and coagulopathy.

After Institutional Review Board approval and informed consent, 11 class I and II patients scheduled for diagnostic or therapeutic (uterine ablation) hysteroscopy under general anesthesia were studied. Blood samples were obtained to measure Hyskon solution levels. Five patients underwent diagnostic procedures, received a smaller volume of Hyskon solution (<260 ml), and had lower serum Hyskon solution levels of 16.4 ± 22.4 mg/dl. In six ablative procedures, larger volumes of Hyskon solution ranging from 360 to 480 ml, resulted in serum Hyskon solution levels of 1467 ± 913 mg/dl. In all patients mean injection pressures were between 0.5 and 3.9 atm; mean intrauterine pressures were between 10 and 160 mm Hg.

We found much intrauterine Hyskon solution absorption or injection during hysteroscopy. Large intravascular volume expansion occurs with pressurized injection, and medium hypertonicity causes dilutional hyponatremia and anemia. This process may contribute to fluid overload and coagulopathy, especially in hemodynamically compromised patients. During hysteroscopy, only the minimum Hyskon solution volume necessary should be used. Injection pressures should be minimized to reduce intravascular injection. With extensive ablative procedures, a two-stage operation may prevent complications of pulmonary edema and coagulopathy.

Correction

In the article by Vintzileos et al. entitled "Relationship between biophysical activities and umbilical cord blood gas values" (AM J OBSTET GYNECOL 1991;165:707-13), on page 711, Table V is entitled "Umbilical artery blood gas values associated with compromised biophysical activities"; it should have been "Umbilical vein blood gas values associated with compromised biophysical activities."

FACULTY OPENINGS IN OBSTETRICS & GYNECOLOGY FOR GENERALISTS/PERINATOLOGISTS

Full time faculty positions at the University of South Alabama, Department of Obstetrics & Gynecology. Excellent opportunity for teaching, research and clinical service. Individuals must be board eligible or certified in Specialty/Sub-specialty. The academic rank and salary will be dependent upon the training and experience of the applicant. These positions are available immediately.

Please contact:

Ian H. Thorneycroft, Ph.D., M.D.
Professor and Chairman

Full Time Faculty Positions Available at Temple University School of Medicine

Department of Obstetrics, Gynecology and Reproductive Sciences

- MATERNAL FETAL MEDICINE
- GYNECOLOGIC ONCOLOGY
- GENERAL OBSTETRICS, GYNECOLOGY, AND INFECTIOUS DISEASE

The Department of Obstetrics, Gynecology and Reproductive Sciences at Temple University is seeking Board Certified or Board Eligible Obstetrician/Gynecologists. Clinical and academic activities are interested in a department providing tertiary services. Temple University Hospital houses a modern Fetal Center, a large Neonatal Intensive Care Unit and a dedicated Gynecology Unit. In addition, state-of-the-art research facilities are available within the department and collaboratively within the University.
